

man pages section 1M: System Administration Commands

Sun Microsystems, Inc.
901 San Antonio Road
Palo Alto, CA 94303-4900
U.S.A.

Part No: 816-0211-06
December 2001

Copyright 2001 Sun Microsystems, Inc. 901 San Antonio Road Palo Alto, CA 94303-4900 U.S.A. All rights reserved.

This product or document is protected by copyright and distributed under licenses restricting its use, copying, distribution, and decompilation. No part of this product or document may be reproduced in any form by any means without prior written authorization of Sun and its licensors, if any. Third-party software, including font technology, is copyrighted and licensed from Sun suppliers.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, docs.sun.com, AnswerBook, AnswerBook2, and Solaris are trademarks, registered trademarks, or service marks of Sun Microsystems, Inc. in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

The OPEN LOOK and Sun™ Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

Federal Acquisitions: Commercial Software—Government Users Subject to Standard License Terms and Conditions.

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Copyright 2001 Sun Microsystems, Inc. 901 San Antonio Road Palo Alto, CA 94303-4900 U.S.A. Tous droits réservés

Ce produit ou document est protégé par un copyright et distribué avec des licences qui en restreignent l'utilisation, la copie, la distribution, et la décompilation. Aucune partie de ce produit ou document ne peut être reproduite sous aucune forme, par quelque moyen que ce soit, sans l'autorisation préalable et écrite de Sun et de ses bailleurs de licence, s'il y en a. Le logiciel détenu par des tiers, et qui comprend la technologie relative aux polices de caractères, est protégé par un copyright et licencié par des fournisseurs de Sun.

Des parties de ce produit pourront être dérivées du système Berkeley BSD licenciés par l'Université de Californie. UNIX est une marque déposée aux Etats-Unis et dans d'autres pays et licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, docs.sun.com, AnswerBook, AnswerBook2, et Solaris sont des marques de fabrique ou des marques déposées, ou marques de service, de Sun Microsystems, Inc. aux Etats-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux Etats-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et Sun™ a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui en outre se conforment aux licences écrites de Sun.

CETTE PUBLICATION EST FOURNIE "EN L'ETAT" ET AUCUNE GARANTIE, EXPRESSE OU IMPLICITE, N'EST ACCORDEE, Y COMPRIS DES GARANTIES CONCERNANT LA VALEUR MARCHANDE, L'APTITUDE DE LA PUBLICATION A REpondre A UNE UTILISATION PARTICULIERE, OU LE FAIT QU'ELLE NE SOIT PAS CONTREFAISANTE DE PRODUIT DE TIERS. CE DENI DE GARANTIE NE S'APPLIQUERAIT PAS, DANS LA MESURE OU IL SERAIT TENU JURIDIQUEMENT NUL ET NON AVENU.

Index 1769

Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the `intro` pages for more information and detail about each section, and `man(1)` for more information about man pages in general.

NAME	This section gives the names of the commands or functions documented, followed by a brief description of what they do.
SYNOPSIS	This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.
	The following special characters are used in this section:
[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.
. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename ...".
	Separator. Only one of the arguments separated by this character can be specified at a time.
{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

PROTOCOL	This section occurs only in subsection 3R to indicate the protocol description file.
DESCRIPTION	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.
IOCTL	This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the <code>ioctl(2)</code> system call is called <code>ioctl</code> and generates its own heading. <code>ioctl</code> calls for a specific device are listed alphabetically (on the man page for that specific device). <code>ioctl</code> calls are used for a particular class of devices all of which have an <code>io</code> ending, such as <code>mtio(7I)</code> .
OPTIONS	This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.
OPERANDS	This section lists the command operands and describes how they affect the actions of the command.
OUTPUT	This section describes the output – standard output, standard error, or output files – generated by the command.
RETURN VALUES	If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.
ERRORS	On failure, most functions place an error code in the global variable <code>errno</code> indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than

	one condition can cause the same error, each condition is described in a separate paragraph under the error code.
USAGE	This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality: Commands Modifiers Variables Expressions Input Grammar
EXAMPLES	This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as <code>example%</code> , or if the user must be superuser, <code>example#</code> . Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.
ENVIRONMENT VARIABLES	This section lists any environment variables that the command or function affects, followed by a brief description of the effect.
EXIT STATUS	This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.
FILES	This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.
ATTRIBUTES	This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See <code>attributes(5)</code> for more information.
SEE ALSO	This section lists references to other man pages, in-house documentation, and outside publications.

DIAGNOSTICS	This section lists diagnostic messages with a brief explanation of the condition causing the error.
WARNINGS	This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.
NOTES	This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.
BUGS	This section describes known bugs and, wherever possible, suggests workarounds.

Introduction

Intro(1M)

NAME	Intro – introduction to maintenance commands and application programs												
DESCRIPTION	<p>This section describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.</p> <p>Because of command restructuring for the Virtual File System architecture, there are several instances of multiple manual pages that begin with the same name. For example, the <code>mount</code>, pages – <code>mount(1M)</code>, <code>mount_cacheufs(1M)</code>, <code>mount_hsfefs(1M)</code>, <code>mount_nfs(1M)</code>, <code>mount_tmpfs(1M)</code>, and <code>mount_ufs(1M)</code>. In each such case the first of the multiple pages describes the syntax and options of the generic command, that is, those options applicable to all FSTypes (file system types). The succeeding pages describe the functionality of the FSType-specific modules of the command. These pages list the command followed by an underscore (<code>_</code>) and the FSType to which they pertain. Note that the administrator should not attempt to call these modules directly. The generic command provides a common interface to all of them. Thus the FSType-specific manual pages should not be viewed as describing distinct commands, but rather as detailing those aspects of a command that are specific to a particular FSType.</p>												
COMMAND SYNTAX	<p>Unless otherwise noted, commands described in this section accept options and other arguments according to the following syntax:</p> <p><i>name</i> [<i>option</i> (s)] [<i>cmdarg</i> (s)] where:</p> <table><tr><td><i>name</i></td><td>The name of an executable file.</td></tr><tr><td><i>option</i></td><td>– <i>noargletter</i>(s) or, – <i>argletter</i>< ><i>optarg</i></td></tr></table> <p>where < > is optional white space.</p> <table><tr><td><i>noargletter</i></td><td>A single letter representing an option without an argument.</td></tr><tr><td><i>argletter</i></td><td>A single letter representing an option requiring an argument.</td></tr><tr><td><i>optarg</i></td><td>Argument (character string) satisfying preceding <i>argletter</i>.</td></tr><tr><td><i>cmdarg</i></td><td>Pathname (or other command argument) <i>not</i> beginning with – or, – by itself indicating the standard input.</td></tr></table>	<i>name</i>	The name of an executable file.	<i>option</i>	– <i>noargletter</i> (s) or, – <i>argletter</i> < > <i>optarg</i>	<i>noargletter</i>	A single letter representing an option without an argument.	<i>argletter</i>	A single letter representing an option requiring an argument.	<i>optarg</i>	Argument (character string) satisfying preceding <i>argletter</i> .	<i>cmdarg</i>	Pathname (or other command argument) <i>not</i> beginning with – or, – by itself indicating the standard input.
<i>name</i>	The name of an executable file.												
<i>option</i>	– <i>noargletter</i> (s) or, – <i>argletter</i> < > <i>optarg</i>												
<i>noargletter</i>	A single letter representing an option without an argument.												
<i>argletter</i>	A single letter representing an option requiring an argument.												
<i>optarg</i>	Argument (character string) satisfying preceding <i>argletter</i> .												
<i>cmdarg</i>	Pathname (or other command argument) <i>not</i> beginning with – or, – by itself indicating the standard input.												
ATTRIBUTES	See <code>attributes(5)</code> for a discussion of the attributes listed in this section.												
SEE ALSO	<code>getopt(1)</code> , <code>getopt(3C)</code> , <code>attributes(5)</code>												
DIAGNOSTICS	Upon termination, each command returns 0 for normal termination and non-zero to indicate troubles such as erroneous parameters, bad or inaccessible data, or other inability to cope with the task at hand. It is called variously “exit code,” “exit status,” or “return code,” and is described only where special conventions are involved.												
NOTES	Unfortunately, not all commands adhere to the standard syntax.												

System Administration Commands

ab2admin(1M)

NAME	ab2admin – command-line interface for AnswerBook2 administration								
SYNOPSIS	<code>/usr/lib/ab2/bin/ab2admin [-h [<i>command</i>]] [-o <i>command</i> [<i>arguments</i>]]</code>								
DESCRIPTION	<p>The <code>ab2admin</code> command is a command-line interface for administering AnswerBook2 collections and documents on a specified AnswerBook2 server. The command can install and uninstall AnswerBook1 and AnswerBook2 collections to a server, scan for locally installed collections and update the server database, and obtain a listing of collections and books.</p> <p><code>ab2admin</code> server management functions include: stopping the server, starting the server, restarting the server, turning the server log files on or off, and rotating the log files. The server can be configured to resolve links to books located on other AnswerBook2 servers.</p> <p><code>ab2admin</code> can also be used to control server access by adding users to or deleting users from the pool of administrative users. The access control can be enabled or disabled.</p> <p><code>ab2admin</code> can connect to any AnswerBook2 server (local or remote). Certain functions (such as <code>stop</code>, <code>start</code>, and <code>restart</code>) apply only to the local AnswerBook2 server. If the AnswerBook2 server is protected by a password, then a user ID and password are required to initiate an administration task.</p> <p>To run <code>ab2admin</code> interactively, type <code>ab2admin</code> from the command line and then enter commands as prompted. It can also be executed entirely from the command line using the <code>-o</code> option.</p>								
OPTIONS	<p>The following options are supported:</p> <table><tr><td><code>-h [<i>command</i>]</code></td><td>Displays help and specified help on a <i>command</i>.</td></tr><tr><td><code>-o <i>sub-command</i> [<i>arguments</i>]</code></td><td>The supported sub-commands are listed below.</td></tr></table>	<code>-h [<i>command</i>]</code>	Displays help and specified help on a <i>command</i> .	<code>-o <i>sub-command</i> [<i>arguments</i>]</code>	The supported sub-commands are listed below.				
<code>-h [<i>command</i>]</code>	Displays help and specified help on a <i>command</i> .								
<code>-o <i>sub-command</i> [<i>arguments</i>]</code>	The supported sub-commands are listed below.								
Sub-commands	<p>The following sub-commands to the <code>-o</code> option are supported:</p> <table><tr><td><code>access_off [-m <i>server</i>] [-p <i>server_port_number</i>]</code></td><td>Disables the server access log file.</td></tr><tr><td><code>access_on [-m <i>server</i>] [-p <i>server_port_number</i>]</code></td><td>Enables the server access log file.</td></tr><tr><td><code>add_admin -u <i>user_id</i> [-m <i>server</i>] [-p <i>server_port_number</i>]</code></td><td>Adds a user to the authorized list of server administrators.</td></tr><tr><td><code>add_coll -d <i>path</i> [-m <i>server</i>] [-p <i>server_port_number</i>]</code></td><td>Adds AnswerBook1 or AnswerBook2 collections to the specified AnswerBook2 server database.</td></tr></table>	<code>access_off [-m <i>server</i>] [-p <i>server_port_number</i>]</code>	Disables the server access log file.	<code>access_on [-m <i>server</i>] [-p <i>server_port_number</i>]</code>	Enables the server access log file.	<code>add_admin -u <i>user_id</i> [-m <i>server</i>] [-p <i>server_port_number</i>]</code>	Adds a user to the authorized list of server administrators.	<code>add_coll -d <i>path</i> [-m <i>server</i>] [-p <i>server_port_number</i>]</code>	Adds AnswerBook1 or AnswerBook2 collections to the specified AnswerBook2 server database.
<code>access_off [-m <i>server</i>] [-p <i>server_port_number</i>]</code>	Disables the server access log file.								
<code>access_on [-m <i>server</i>] [-p <i>server_port_number</i>]</code>	Enables the server access log file.								
<code>add_admin -u <i>user_id</i> [-m <i>server</i>] [-p <i>server_port_number</i>]</code>	Adds a user to the authorized list of server administrators.								
<code>add_coll -d <i>path</i> [-m <i>server</i>] [-p <i>server_port_number</i>]</code>	Adds AnswerBook1 or AnswerBook2 collections to the specified AnswerBook2 server database.								

```

add_server -M alternate_server -P alternate_server_port_number
           [ -m server ] [ -p server_port_number ]
           Adds an alternate server to the specified server.

auth_off [ -m server ] [ -p server_port_number ]
           Disables server administration verification.

auth_on [ -m server ] [ -p server_port_number ]
           Enables server administration verification.

autostart_no [ -m server ] [ -p server_port_number ]
           Stops AnswerBook2 server from starting automatically when system is (re)booted.

autostart_yes [ -m server ] [ -p server_port_number ]
           Causes AnswerBook2 server to start automatically when system is (re)booted.

browser [ -m server ] [ -p server_port_number ]
           Launches a web browser for accessing AnswerBook2 Administration pages.

change_password -u admin_id [ -m server ] [ -p server_port_number ]
           Changes authorized administrator's password.

del_admin -u user_id [ -m server ] [ -p server_port_number ]
           Deletes a user from the list of authorized server administrators.

del_coll -t collection_title [ -m server ] [ -p server_port_number ]
           Removes AnswerBook1 or AnswerBook2 collections from the specified server's
           database.

del_server -M alternate_server -P alternate_server_port_number
           [ -m server ] [ -p server_port_number ]
           Deletes alternate server from list of servers known to the specified server.

error_off [ -m server ] [ -p server_port_number ]
           Disables the server error log file.

error_on [ -m server ] [ -p server_port_number ]
           Enables the server error log file.

help [ command ]
           Lists all information about a particular command or all commands.

list [ -m server ] [ -p server_port_number ]
           Lists AnswerBook1 and AnswerBook2 collections available on the specified server.
           The listing includes the books contained within collections.

list_server [ -m server ] [ -p server_port_number ]
           Lists all alternate servers defined for the specified server.

menu
           Displays a condensed list of command options.

modify_server_name -s new_server_name [ -m server ] [ -p server_port_number ]
           Modifies the server's name.

```

ab2admin(1M)

`modify_server_port -a new_server_port_number [-m server]`
`[-p server_port_number]`
Modifies the server's port number.

`restart`
Restarts local AnswerBook2 server. Requires root access.

`rotate_access [-m server] [-p server_port_number]`
Saves and resets the server access log file.

`rotate_error [-m server] [-p server_port_number]`
Saves and resets the server error log file.

`scan [-m server] [-p server_port_number]`
Scans for locally installed collections (AnswerBook1 or AnswerBook2) and updates the collections on the specified server's database.

`start`
Starts local AnswerBook2 server. Requires root access.

`start -D`
Starts local AnswerBook2 server in debug mode. Requires root access.

`stop`
Stops local AnswerBook2 server. Requires root access.

`view_access [-m server] [-p server_port_number]`
Views the contents of the server access log file.

`view_config [-m server] [-p server_port_number]`
Views the configuration settings of the server.

`view_error [-m server] [-p server_port_number]`
Views the contents of the server error log file.

USAGE

`quit` Exit interactive mode.

`q` Exit interactive mode.

`bye` Exit interactive mode.

`exit` Exit interactive mode.

`? [command]` Get help in interactive mode.

`h [command]` Get help in interactive mode.

EXAMPLES

EXAMPLE 1 Listing AnswerBook2 collections available on a server

To list the collections available on a server named `foo.com`, using port number `8888`:

```
example% ab2admin -o list -m foo.com -p 8888
```

EXAMPLE 1 Listing AnswerBook2 collections available on a server (Continued)

EXAMPLE 2 Using interactive mode to list collections

To use `ab2admin` in interactive mode for the same operation as shown above:

```
example% ab2admin
>> list -m foo.com -p 8888
```

EXAMPLE 3 Installing an AnswerBook2 collection

To install an AnswerBook2 collection using the `pkgadd` utility:

```
example# pkgadd -d package_directory/ SUNWabsdk
```

The collection directory structure will be copied into the system (by default) to `/opt/answerbooks/`

EXAMPLE 4 Installing an AnswerBook2 collection not updated to server database

To install an AnswerBook2 collection that has been introduced to the system (via `pkgadd`) but did not get updated to the server database:

```
example# ab2admin -o add_coll -d
/opt/answerbooks/english/solaris_2.6/SUNWabsdk
```

(Note: `-d path` must include the `collinfo` file (for an AnswerBook2 collection) or the `ab_cardcatalog` file (for an AnswerBook1 collection).

EXAMPLE 5 Inspecting the definition of an AnswerBook1 collection

To inspect how an AnswerBook1 collection is defined:

```
example% cat /opt/SUNWans/ab_cardcatalog
:id=SUNWab_10_4: \
:version=: \
:title=Solaris XGL 3.1 AnswerBook: \
:tocpath=/net/elirium.Eng/export/answerbook/Solaris_2.4/SUNWaxg/toc: \
:pspath=/net/elirium.Eng/export/answerbook/Solaris_2.4/SUNWaxg/ps: \
:indexpath=/net/elirium.Eng/export/answerbook/Solaris_2.4/SUNWaxg/inde
```

EXAMPLE 6 Inspecting the definition of an AnswerBook2 collection

To inspect how an AnswerBook2 collection is defined:

```
example% cat/opt/answerbooks/english/solaris_2.6/SUNabsd/collinfo
dwCollections {
  coll.45.4 dwCollection
}
dwSetParam coll.45.4 {
  location /opt/answerbooks/english/solaris_2.6/SUNWabsdk
  title "Solaris 2.6 Software Developer AnswerBook Vol 1"
  type EbtCollection
```

EXAMPLE 6 Inspecting the definition of an AnswerBook2 collection (Continued)

}

ATTRIBUTES See attributes(5) for a discussion of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWab2u

SEE ALSO attributes(5)

NAME	ab2cd – run AnswerBook2 server from the Documentation CD
SYNOPSIS	ab2cd [-h] [stop] [-d <i>path_to_CD_mountpoint</i>] [-p <i>port_number</i>] [-s] [-v]
DESCRIPTION	The ab2cd utility runs an AnswerBook2 server directly from the Documentation CD by creating necessary space in the /tmp/.ab2 directory to store configuration files and other necessary data. It attempts to launch a web browser with the appropriate URL to display the library page for the user.
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -d <i>path_to_CD_mountpoint</i> Specifies a mount point for the CD other than /cdrom. -h Displays a usage statement and a brief list of options. -p <i>port_number</i> Specifies a port number to use for the server. Default value is 8888. -s Scans for AnswerBook1 and AnswerBook2 collections installed on the system and adds them to the database of the AnswerBook2 server running from the CD. stop Stops AnswerBook2 server running from the CD and removes any files in the /tmp/.ab2 directory. -v Returns the version number of the ab2cd script.
USAGE	ab2cd expects /cdrom as the default mount point. To override this default, use the -d option. Use the stop option to shut down the server running from the Documentation CD. This option cleans up any files in /tmp/.ab2. By default, the ab2cd script attempts to launch a web browser (preferably Netscape Navigator) with the appropriate URL to display the library page for the user. If Netscape is not found in the user's path, it then looks for other browsers. For an AnswerBook2 server to read multi-byte characters correctly, the iconv utility must be installed on the system. If it is not, the ab2cd script starts the server, but the user cannot correctly view Asian book titles or other information.
EXAMPLES	EXAMPLE 1 Running ab2cd In this example, the user runs the AnswerBook2 server from the CD. The ab2cd script then offers to launch a web browser with the URL for the library page. example# ab2cd Scanning for collections and attempting to start AnswerBook2 server from CD. Please wait ... NAME	ab2regsvr – register an AnswerBook2 document server with FNS (Federated Naming Service)				
SYNOPSIS	<code>/usr/lib/ab2/bin/ab2regsvr [-d] [-h] [-l] [-r] server-url</code>				
DESCRIPTION	<p>The <code>ab2regsvr</code> command sets up the appropriate name space for the AnswerBook2 document server, depending on which naming service has been selected by the system administrator. The naming service can be <code>NIS</code>, <code>NIS+</code>, or <code>files</code>.</p> <p>To register the server with <code>NIS</code>, it is necessary to be logged in as root on the <code>NIS</code> master server. To register with <code>NIS+</code>, administrative privileges are necessary; you can be on either the <code>NIS+</code> master or <code>NIS+</code> client. To register for <code>files</code>, you must be logged in as root on the machine; this is machine-specific and is not seen on other machines.</p> <p>Registering an AnswerBook2 document server with FNS allows a system administrator to specify the default AnswerBook2 server that users access when they select AnswerBook2 from the CDE desktop or from the OpenWindows root menu. The server's URL does not have to be entered into a web browser.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -d Deletes the AnswerBook2 entry in FNS. -h Displays a usage statement and a brief list of options. -l Lists currently registered AnswerBook2 document servers. -r Replaces the currently defined URL for AnswerBook2 with a new URL. 				
OPERANDS	<p>The following operand is supported:</p> <p><code>server-url</code> Fully qualified URL for users to access the registered server.</p>				
EXAMPLES	<p>EXAMPLE 1 Using the <code>ab2regsvr</code> command</p> <p>To register a server named <code>imaserver</code> located at port <code>8888</code>:</p> <pre>example# ab2regsvr http://imaserver.eng.sun.com:8888/</pre>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWab2u</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWab2u
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWab2u				
SEE ALSO	<code>fnlookup(1)</code> , <code>attributes(5)</code> , <code>fns(5)</code>				

accept(1M)

NAME	accept, reject – accept or reject print requests						
SYNOPSIS	accept <i>destination</i> ... reject [-r <i>reason</i>] <i>destination</i> ...						
DESCRIPTION	<p>accept allows the queuing of print requests for the named destinations.</p> <p>reject prevents queuing of print requests for the named destinations.</p> <p>Use <code>lpstat -a</code> to check if destinations are accepting or rejecting print requests.</p> <p>accept and reject must be run on the print server; they have no meaning to a client system.</p>						
OPTIONS	<p>The following options are supported for <code>reject</code>:</p> <p>-r <i>reason</i> Assigns a reason for rejection of print requests for <i>destination</i>. Enclose <i>reason</i> in quotes if it contains blanks. <i>reason</i> is reported by <code>lpstat -a</code>. By default, <i>reason</i> is unknown reason for existing destinations, and new <code>printer</code> for destinations added to the system but not yet accepting requests.</p>						
OPERANDS	<p>The following operands are supported.</p> <p><i>destination</i> The name of the destination accepting or rejecting print requests. Destination specifies the name of a printer or class of printers (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic name. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic names.</p>						
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p><i>non-zero</i> An error occurred.</p>						
FILES	<code>/var/spool/lp/*</code> LP print queue.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWpcu</td></tr><tr><td>CSI</td><td>Enabled (see NOTES)</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWpcu	CSI	Enabled (see NOTES)
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWpcu						
CSI	Enabled (see NOTES)						
SEE ALSO	<code>enable(1)</code> , <code>lp(1)</code> , <code>lpstat(1)</code> , <code>lpadmin(1M)</code> , <code>lpsched(1M)</code> , <code>printers.conf(4)</code> , <code>attributes(5)</code>						

accept(1M)

NOTES | accept and reject affect only queueing on the print server's spooling system. Requests made from a client system remain queued in the client system's queueing mechanism until they are cancelled or accepted by the print server's spooling system.

accept is CSI-enabled except for the *destination* name.

acct(1M)

NAME	acct, acctdisk, acctdusg, accton, acctwtmp, closewtmp, utmp2wtmp – overview of accounting and miscellaneous accounting commands
SYNOPSIS	<pre>/usr/lib/acct/acctdisk /usr/lib/acct/acctdusg [-u filename] [-p filename] /usr/lib/acct/accton [filename] /usr/lib/acct/acctwtmp reason filename /usr/lib/acct/closewtmp /usr/lib/acct/utmp2wtmp</pre>
DESCRIPTION	<p>Accounting software is structured as a set of tools (consisting of both C programs and shell procedures) that can be used to build accounting systems. acctsh(1M) describes the set of shell procedures built on top of the C programs.</p> <p>Connect time accounting is handled by various programs that write records into /var/adm/wtmpx, as described in utmpx(4). The programs described in acctcon(1M) convert this file into session and charging records, which are then summarized by acctmerg(1M).</p> <p>Process accounting is performed by the system kernel. Upon termination of a process, one record per process is written to a file (normally /var/adm/pacct). The programs in acctprc(1M) summarize this data for charging purposes; acctcms(1M) is used to summarize command usage. Current process data may be examined using acctcom(1).</p> <p>Process accounting records and connect time accounting records (or any accounting records in the tacct format described in acct(3HEAD)) can be merged and summarized into total accounting records by acctmerg (see tacct format in acct(3HEAD)). prtacct (see acctsh(1M)) is used to format any or all accounting records.</p> <p>acctdisk reads lines that contain user ID, login name, and number of disk blocks and converts them to total accounting records that can be merged with other accounting records. acctdisk returns an error if the input file is corrupt or improperly formatted.</p> <p>acctdusg reads its standard input (usually from find / -print) and computes disk resource consumption (including indirect blocks) by login.</p> <p>accton without arguments turns process accounting off. If filename is given, it must be the name of an existing file, to which the kernel appends process accounting records (see acct(2) and acct(3HEAD)).</p> <p>acctwtmp writes a utmpx(4) record to filename. The record contains the current time and a string of characters that describe the reason. A record type of ACCOUNTING is</p>

assigned (see `utmpx(4)`) *reason* must be a string of 11 or fewer characters, numbers, \$, or spaces. For example, the following are suggestions for use in reboot and shutdown procedures, respectively:

```
acctwtmp "acctg on" /var/adm/wtmpx
acctwtmp "acctg off" /var/adm/wtmpx
```

For each user currently logged on, `closewtmp` puts a false `DEAD_PROCESS` record in the `/var/adm/wtmpx` file. `runacct` (see `runacct(1M)`) uses this false `DEAD_PROCESS` record so that the connect accounting procedures can track the time used by users logged on before `runacct` was invoked.

For each user currently logged on, `runacct` uses `utmp2wtmp` to create an entry in the file `/var/adm/wtmpx`, created by `runacct`. Entries in `/var/adm/wtmpx` enable subsequent invocations of `runacct` to account for connect times of users currently logged in.

OPTIONS The following options are supported:

`-u filename` Places in *filename* records consisting of those filenames for which `acctdusg` charges no one (a potential source for finding users trying to avoid disk charges).

`-p filename` Specifies a password file, *filename*. This option is not needed if the password file is `/etc/passwd`.

**ENVIRONMENT
VARIABLES**

If any of the `LC_*` variables (`LC_TYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `acct` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `acct` behaves.

`LC_CTYPE` Determines how `acct` handles characters. When `LC_CTYPE` is set to a valid value, `acct` can display and handle text and filenames containing valid characters for that locale. `acct` can display and handle Extended Unix Code (EUC) characters where any character can be 1, 2, or 3 bytes wide. `acct` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

`LC_TIME` Determines how `acct` handles date and time formats. In the "C" locale, date and time handling follows the U.S. rules.

FILES

`/etc/passwd` Used for login name to user ID conversions.

`/usr/lib/acct` Holds all accounting commands listed in sub-class 1M of this manual.

`/var/adm/pacct` Current process accounting file.

System Administration Guide: Basic Administration

NAME	acctadm – configure extended accounting facility
SYNOPSIS	<code>/usr/sbin/acctadm [-DErux] [-d <i>resource_list</i>] [-e <i>resource_list</i>] [-f <i>filename</i>] [task process]</code>
DESCRIPTION	acctadm configures various attributes of the extended accounting facility. Without arguments, acctadm displays the current status of the extended accounting facility.
OPTIONS	<p>The following options are supported:</p> <p>-d <i>resource_list</i> Disable reporting of resource usage for resource. Specify <i>resource_list</i> as a comma-separated list of resources or resource groups.</p> <p style="padding-left: 100px;">This option requires an operand. See OPERANDS.</p> <p>-D Disable accounting of the given operand type without closing the accounting file. This option can be used to temporarily stop writing accounting records to the accounting file without closing it. To close the file use the -x option. See -x.</p> <p>-e <i>resource_list</i> Enable reporting of resource usage for resource. Specify <i>resource_list</i> as a comma-separated list of resources or resource groups.</p> <p style="padding-left: 100px;">This option requires an operand. See OPERANDS.</p> <p>-E Enable accounting of the given operand type without sending the accounting output to a file. This option requires an operand. See OPERANDS.</p> <p>-f <i>filename</i> Send the accounting output for the given operand type to <i>filename</i>. If <i>filename</i> exists, its contents are lost.</p> <p style="padding-left: 100px;">This option requires an operand. See OPERANDS.</p> <p>-r Display available resource groups.</p> <p style="padding-left: 100px;">When this option is used with an operand, it displays resource groups available for a given accounting type. When no operand is specified, this option displays resource groups for all available accounting types. See OPERANDS.</p> <p>-u Configure accounting based on the contents of <code>/etc/acctadm.conf</code>.</p> <p>-x Deactivate accounting of the given operand type. This option also closes the accounting file for the given accounting type if it is currently open.</p> <p style="padding-left: 100px;">This option requires an operand. See OPERANDS.</p>
OPERANDS	The -d , -D , -e , -E , -f , and -x options require an operand.

acctadm(1M)

The following operands are supported:

- process Run `acctadm` on the process accounting components of the extended account facility.
- task Run `acctadm` on the task accounting components of the extended account facility.

The optional final parameter to `acctadm` represents whether the command should act on the process or system task accounting components of the extended account facility.

EXAMPLES

EXAMPLE 1 Displaying current status

The following command displays the current status. In this example, system task accounting is active and tracking only CPU resources. Process accounting is not active.

```
$ acctadm
      Task accounting: active
      Task accounting file: /var/adm/exacct/task
      Tracked task resources: extended,mstate
      Untracked task resources: host
      Process accounting: inactive
      Process accounting file: none
      Tracked process resources: none
      Untracked process resources: extended,host,mstate
```

EXAMPLE 2 Activating basic process accounting

The following command activates basic process accounting:

```
$ acctadm -e basic -f /var/adm/exacct/proc process
```

EXAMPLE 3 Displaying available resource groups

The following command displays available resource groups:

```
$ acctadm -r
process:
  extended pid,uid,gid,cpu,time,command,tty,projid,taskid,ancpid,
           wait-status,flag
  basic    pid,uid,gid,cpu,time,command,tty,flag
task:
  extended taskid,projid,cpu,time,host,mstate,anctaskid
  basic    taskid,projid,cpu,time
```

EXAMPLE 4 Displaying resource groups for task accounting

The following command displays resource groups for task accounting:

```
$ acctadm -r task
  extended taskid,projid,cpu,time,host,mstate,anctaskid
  basic    taskid,projid,cpu,time
```

EXIT STATUS The following exit values are returned:

- 0 Successful completion.

 The modifications to the current configuration were valid and made successfully.
- 1 An error occurred.

 A fatal error occurred either in obtaining or modifying the accounting configuration.
- 2 Invalid command line options were specified.

FILES /etc/acctadm.conf

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `acct(2)`, `attributes(5)`

NOTES Both extended accounting and regular accounting can be active.

Available resources can vary from system to system, and from platform to platform.

acctcms(1M)

NAME	acctcms – command summary from process accounting records
SYNOPSIS	<code>/usr/lib/acct/acctcms [-a [-o] [-p]] [-c] [-j] [-n] [-s] [-t]</code> <i>filename...</i>
DESCRIPTION	acctcms reads one or more <i>filenames</i> , normally in the form described in acct(3HEAD). It adds all records for processes that executed identically named commands, sorts them, and writes them to the standard output, normally using an internal summary format.
OPTIONS	<p>-a Print output in ASCII rather than in the internal summary format. The output includes command name, number of times executed, total kcore-minutes, total CPU minutes, total real minutes, mean size (in K), mean CPU minutes per invocation, "hog factor," characters transferred, and blocks read and written, as in acctcom(1). Output is normally sorted by total kcore-minutes.</p> <p>Use the following options only with the -a option:</p> <p>-o Output a (non-prime) offshift-time-only command summary.</p> <p>-p Output a prime-time-only command summary.</p> <p>When -o and -p are used together, a combination prime-time and non-prime-time report is produced. All the output summaries are total usage except number of times executed, CPU minutes, and real minutes, which are split into prime and non-prime.</p> <p>-c Sort by total CPU time, rather than total kcore-minutes.</p> <p>-j Combine all commands invoked only once under "***other".</p> <p>-n Sort by number of command invocations.</p> <p>-s Any file names encountered hereafter are already in internal summary format.</p> <p>-t Process all records as total accounting records. The default internal summary format splits each field into prime and non-prime-time parts. This option combines the prime and non-prime time parts into a single field that is the total of both, and provides upward compatibility with old style acctcms internal summary format records.</p>
EXAMPLES	<p>EXAMPLE 1 Using the acctcms command.</p> <p>A typical sequence for performing daily command accounting and for maintaining a running total is:</p> <pre>example% acctcms filename ... > today example% cp total previoustotal example% acctcms -s today previoustotal > total example% acctcms -a -s today</pre>

EXAMPLE 1 Using the `acctcms` command. (Continued)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

SEE ALSO `acctcom(1)`, `acct(1M)`, `acctcon(1M)`, `acctmerg(1M)`, `acctprc(1M)`, `acctsh(1M)`, `fwtmp(1M)`, `runacct(1M)`, `acct(2)`, `acct(3HEAD)`, `utmpx(4)`, `attributes(5)`

NOTES Unpredictable output results if `-t` is used on new style internal summary format files, or if it is not used with old style internal summary format files.

acctcon(1M)

NAME	acctcon, acctcon1, acctcon2 – connect-time accounting
SYNOPSIS	<pre>/usr/lib/acct/acctcon [-l <i>lineuse</i>] [-o <i>reboot</i>] /usr/lib/acct/acctcon1 [-p] [-t] [-l <i>lineuse</i>] [-o <i>reboot</i>] /usr/lib/acct/acctcon2</pre>
DESCRIPTION	<p>acctcon converts a sequence of login/logoff records to total accounting records (see the <code>tacct</code> format in <code>acct(3HEAD)</code>). The login/logoff records are read from standard input. The file <code>/var/adm/wtmpx</code> is usually the source of the login/logoff records; however, because it might contain corrupted records or system date changes, it should first be fixed using <code>wtmpfix</code>. The fixed version of file <code>/var/adm/wtmpx</code> can then be redirected to <code>acctcon</code>. The <code>tacct</code> records are written to standard output.</p> <p>acctcon is a combination of the programs <code>acctcon1</code> and <code>acctcon2</code>. <code>acctcon1</code> converts login/logoff records, taken from the fixed <code>/var/adm/wtmpx</code> file, to ASCII output. <code>acctcon2</code> reads the ASCII records produced by <code>acctcon1</code> and converts them to <code>tacct</code> records. <code>acctcon1</code> can be used with the <code>-l</code> and <code>-o</code> options, described below, as well as with the <code>-p</code> and <code>-t</code> options.</p>
OPTIONS	<p><code>-p</code> Print input only, showing line name, login name, and time (in both numeric and date/time formats).</p> <p><code>-t</code> <code>acctcon1</code> maintains a list of lines on which users are logged in. When it reaches the end of its input, it emits a session record for each line that still appears to be active. It normally assumes that its input is a current file, so that it uses the current time as the ending time for each session still in progress. The <code>-t</code> flag causes it to use, instead, the last time found in its input, thus assuring reasonable and repeatable numbers for non-current files.</p> <p><code>-l <i>lineuse</i></code> <i>lineuse</i> is created to contain a summary of line usage showing line name, number of minutes used, percentage of total elapsed time used, number of sessions charged, number of logins, and number of logoffs. This file helps track line usage, identify bad lines, and find software and hardware oddities. Hangup, termination of <code>login(1)</code> and termination of the login shell each generate logoff records, so that the number of logoffs is often three to four times the number of sessions. See <code>init(1M)</code> and <code>utmpx(4)</code>.</p> <p><code>-o <i>reboot</i></code> <code>reboot</code> is filled with an overall record for the accounting period, giving starting time, ending time, number of reboots, and number of date changes.</p>
EXAMPLES	<p>EXAMPLE 1 Using the <code>acctcon</code> command.</p> <p>The <code>acctcon</code> command is typically used as follows:</p> <pre>example% acctcon -l lineuse -o reboots < tmpwtmp > ctacct</pre> <p>The <code>acctcon1</code> and <code>acctcon2</code> commands are typically used as follows:</p>

EXAMPLE 1 Using the `acctcon` command. (Continued)

```
example% acctcon1 -l lineuse -o reboots < tmpwtmp | sort +1n +2 > ctmp
example% acctcon2 < ctmp > ctacct
```

FILES /var/adm/wtmpx History of user access and administration information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

SEE ALSO `acctcom(1)`, `login(1)`, `acct(1M)`, `acctcms(1M)`, `acctmerg(1M)`, `acctprc(1M)`, `acctsh(1M)`, `fwtmp(1M)`, `init(1M)`, `runacct(1M)`, `acct(2)`, `acct(3HEAD)`, `utmpx(4)`, `attributes(5)`

System Administration Guide: Basic Administration

NOTES The line usage report is confused by date changes. Use `wtmpfix` (see `fwtmp(1M)`), with the `/var/adm/wtmpx` file as an argument, to correct this situation.

During a single invocation of any given command, the `acctcon`, `acctcon1`, and `acctcon2` commands can process a maximum of:

- 6000 distinct session
- 1000 distinct terminal lines
- 2000 distinct login names

If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

acctmerg(1M)

NAME acctmerg – merge or add total accounting files

SYNOPSIS `/usr/lib/acct/acctmerg [-a] [-i] [-p] [-t] [-u] [-v] [filename] ...`

DESCRIPTION acctmerg reads its standard input and up to nine additional files, all in the `tacct` format (see `acct(3HEAD)`) or an ASCII version thereof. It merges these inputs by adding records whose keys (normally user ID and name) are identical, and expects the inputs to be sorted on those keys.

OPTIONS

- a Produce output in ASCII version of `tacct`.
- i Produce input in ASCII version of `tacct`.
- p Print input with no processing.
- t Produce a single record that totals all input.
- u Summarize by user ID, rather than by user ID and name.
- v Produce output in verbose ASCII format, with more precise notation for floating-point numbers.

EXAMPLES **EXAMPLE 1** Using the `acctmerg` command.

The following sequence is useful for making "repairs" to any file kept in this format:

```
example% acctmerg -v <filename1 >filename2
```

Edit `filename2` as you want:

```
example% acctmerg -i <filename2 >filename1
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

System Administration Guide: Basic Administration

NAME	acctprc, acctprc1, acctprc2 – process accounting				
SYNOPSIS	<pre> /usr/lib/acct/acctprc /usr/lib/acct/acctprc1 [ctmp] /usr/lib/acct/acctprc2 </pre>				
DESCRIPTION	<p>acctprc reads the standard input, in the form described by , and converts it to total accounting records (see the tacct record in acct(3HEAD)). acctprc divides CPU time into prime time and non-prime time and determines mean memory size (in memory segment units). acctprc then summarizes the tacct records, according to user IDs, and adds login names corresponding to the user IDs. The summarized records are then written to the standard output. acctprc1 reads input in the form described by acct(3HEAD), adds login names corresponding to user IDs, then writes for each process an ASCII line giving user ID, login name, prime CPU time (tics), non-prime CPU time (tics), and mean memory size (in memory segment units). If ctmp is given, it should contain a list of login sessions sorted by user ID and login name. If this file is not supplied, it obtains login names from the password file, just as acctprc does. The information in ctmp helps it distinguish between different login names that share the same user ID.</p> <p>From the standard input, acctprc2 reads records in the form written by acctprc1, summarizes them according to user ID and name, then writes the sorted summaries to the standard output as total accounting records.</p>				
EXAMPLES	<p>EXAMPLE 1 Examples of acctprc.</p> <p>The acctprc command is typically used as shown below:</p> <pre>example% acctprc < /var/adm/pacct > ptacct</pre> <p>The acctprc1 and acctprc2s commands are typically used as shown below:</p> <pre>example% acctprc1 ctmp </var/adm/pacct example% acctprc2 > ptacct</pre>				
FILES	/etc/passwd system password file				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWaccu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWaccu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWaccu				
SEE ALSO	acctcom(1), acct(1M), acctcms(1M), acctcon(1M), acctmerg(1M), acctsh(1M), cron(1M), fwtmp(1M), runacct(1M), acct(2), acct(3HEAD), utmpx(4), attributes(5)				

acctprc(1M)

NOTES | Although it is possible for `acctprc1` to distinguish among login names that share user IDs for commands run from a command line, it is difficult for `acctprc1` to make this distinction for commands invoked in other ways. A command run from `cron(1M)` is an example of where `acctprc1` might have difficulty. A more precise conversion can be done using the `acctwtmp` program in `acct(1M)`. `acctprc` does not distinguish between users with identical user IDs.

A memory segment of the mean memory size is a unit of measure for the number of bytes in a logical memory segment on a particular processor.

During a single invocation of any given command, the `acctprc`, `acctprc1`, and `acctprc2` commands can process a maximum of

- 6000 distinct sessions
- 1000 distinct terminal lines
- 2000 distinct login names

If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

NAME	acctsh, chargefee, ckpacct, dodisk, lastlogin, monacct, nulladm, prctmp, prdaily, prtacct, shutacct, startup, turnacct – shell procedures for accounting
SYNOPSIS	<pre> /usr/lib/acct/chargefee login-name number /usr/lib/acct/ckpacct [blocks] /usr/lib/acct/dodisk [-o] [filename...] /usr/lib/acct/lastlogin /usr/lib/acct/monacct number /usr/lib/acct/nulladm filename... /usr/lib/acct/prctmp filename /usr/lib/acct/prdaily [-c] [-l] [mddd] /usr/lib/acct/prtacct filename [' heading '] /usr/lib/acct/shutacct [' reason '] /usr/lib/acct/startup /usr/lib/acct/turnacct on off switch </pre>
chargefee Command	chargefee can be invoked to charge a <i>number</i> of units to <i>login-name</i> . A record is written to <code>/var/adm/fee</code> , to be merged with other accounting records by <code>runacct(1M)</code> .
ckpacct Command	ckpacct should be initiated using <code>cron(1M)</code> to periodically check the size of <code>/var/adm/pacct</code> . If the size exceeds <i>blocks</i> , 500 by default, <code>turnacct</code> will be invoked with argument <code>switch</code> . To avoid a conflict with <code>turnacct switch</code> execution in <code>runacct</code> , do not run <code>ckpacct</code> and <code>runacct</code> simultaneously. If the number of free disk blocks in the <code>/var</code> file system falls below 500, <code>ckpacct</code> will automatically turn off the collection of process accounting records via the <code>off</code> argument to <code>turnacct</code> . When at least 500 blocks are restored, the accounting will be activated again on the next invocation of <code>ckpacct</code> . This feature is sensitive to the frequency at which <code>ckpacct</code> is executed, usually by <code>cron</code> .
dodisk Command	dodisk should be invoked by <code>cron</code> to perform the disk accounting functions.
lastlogin Command	lastlogin is invoked by <code>runacct(1M)</code> to update <code>/var/adm/acct/sum/loginlog</code> , which shows the last date on which each person logged in.
monacct Command	monacct should be invoked once each month or each accounting period. <i>number</i> indicates which month or period it is. If <i>number</i> is not given, it defaults to the current month (01–12). This default is useful if <code>monacct</code> is to be executed using <code>cron(1M)</code> on the first day of each month. <code>monacct</code> creates summary files in <code>/var/adm/acct/fiscal</code> and restarts the summary files in <code>/var/adm/acct/sum</code> .

acctsh(1M)

nulladm Command	nulladm creates <i>filename</i> with mode 664 and ensures that owner and group are adm. It is called by various accounting shell procedures.
prctmp Command	prctmp can be used to print the session record file (normally <i>/var/adm/acct/nite/ctmp</i> created by acctcon1 (see acctcon(1M))).
prdaily Command	prdaily is invoked by runacct(1M) to format a report of the previous day's accounting data. The report resides in <i>/var/adm/acct/sum/rprt/mmdd</i> where <i>mmdd</i> is the month and day of the report. The current daily accounting reports may be printed by typing prdaily. Previous days' accounting reports can be printed by using the <i>mmdd</i> option and specifying the exact report date desired.
prtacct Command	prtacct can be used to format and print any total accounting (<i>tacct</i>)file.
shutacct Command	shutacct is invoked during a system shutdown to turn process accounting off and append a <i>reason</i> record to <i>/var/adm/wtmpx</i> .
startup Command	startup can be invoked when the system is brought to a multi-user state to turn process accounting on.
turnacct Command	turnacct is an interface to accton (see acct(1M)) to turn process accounting on or off. The switch argument moves the current <i>/var/adm/pacct</i> to the next free name in <i>/var/adm/pacctincr</i> (where <i>incr</i> is a number starting with 1 and incrementing by one for each additional <i>pacct</i> file), then turns accounting back on again. This procedure is called by ckpacct and thus can be taken care of by the cron and used to keep <i>pacct</i> to a reasonable size. shutacct uses turnacct to stop process accounting. startup uses turnacct to start process accounting.

OPTIONS The following options are supported:

- c This option prints a report of exceptional resource usage by command, and may be used on current day's accounting data only.
- l This option prints a report of exceptional usage by login id for the specified date. Previous daily reports are cleaned up and therefore inaccessible after each invocation of monacct.
- o This option uses acctdusg (see acct(1M)) to do a slower version of disk accounting by login directory. *filenames* specifies the one or more filesystem names where disk accounting will be done. If *filenames* are used, disk accounting will be done on these filesystems only. If the -o option is used, *filenames* should be mount points of mounted filesystems. If the -o option is omitted, *filenames* should be the special file names of mountable filesystems.

FILES */usr/lib/acct*
holds all accounting commands listed in section 1M of this manual
/usr/lib/acct/ptecms.awk
contains the limits for exceptional usage by command name

/usr/lib/acct/ptelus.awk
 contains the limits for exceptional usage by login ID

/var/adm/acct/fiscal
 fiscal reports directory

/var/adm/acct/nite
 working directory

/var/adm/acct/sum
 summary directory contains information for monacct

/var/adm/acct/sum/loginlog
 file updated by last login

/var/adm/fee
 accumulator for fees

/var/adm/pacct
 current file for per-process accounting

/var/adm/pacctincr
 used if pacct gets large and during execution of daily accounting procedure

/var/adm/wtmpx
 history of user access and administration information

NOTES See runacct(1M) for the main daily accounting shell script, which performs the accumulation of connect, process, fee, and disk accounting on a daily basis. It also creates summaries of command usage.

adbgen(1M)

NAME	adbgen – generate adb script												
SYNOPSIS	<code>/usr/lib/adb/adbgen [-m <i>model</i>] <i>filename</i>.adb . . .</code>												
DESCRIPTION	<p>adbgen makes it possible to write adb(1) scripts that do not contain hard-coded dependencies on structure member offsets. The input to adbgen is a file named <i>filename</i>.adb that contains header information, then a null line, then the name of a structure, and finally an adb script. adbgen only deals with one structure per file; all member names are assumed to be in this structure. The output of adbgen is an adb script in <i>filename</i>. adbgen operates by generating a C program which determines structure member offsets and sizes, which in turn generate the adb script.</p> <p>The header lines, up to the null line, are copied verbatim into the generated C program. Typically, these are <code>#include</code> statements, which include the headers containing the relevant structure declarations.</p> <p>The adb script part may contain any valid adb commands (see adb(1)), and may also contain adbgen requests, each enclosed in braces (<code>{ }</code>). Request types are:</p> <ul style="list-style-type: none">■ Print a structure member. The request form is <code>{member, format}</code>. <i>member</i> is a member name of the <i>structure</i> given earlier, and <i>format</i> is any valid adb format request or any of the adbgen format specifiers (such as <code>{POINTER}</code>) listed below. For example, to print the <code>p_pid</code> field of the <i>proc</i> structure as a decimal number, you would write <code>{p_pid, d}</code>.■ Print the appropriate adb format character for the given adbgen format specifier. This action takes the data model into consideration. The request form is <code>{format specifier}</code>. The valid adbgen format specifiers are:<table><tr><td><code>{POINTER}</code></td><td>pointer value in hexadecimal</td></tr><tr><td><code>{LONGDEC}</code></td><td>long value in decimal</td></tr><tr><td><code>{ULONGDEC}</code></td><td>unsigned long value in decimal</td></tr><tr><td><code>{ULONGHEX}</code></td><td>unsigned long value in hexadecimal</td></tr><tr><td><code>{LONGOCT}</code></td><td>long value in octal</td></tr><tr><td><code>{ULONGOCT}</code></td><td>unsigned long value in octal</td></tr></table>■ Reference a structure member. The request form is <code>{*member, base}</code>. <i>member</i> is the member name whose value is desired, and <i>base</i> is an adb register name which contains the base address of the structure. For example, to get the <code>p_pid</code> field of the <i>proc</i> structure, you would get the <i>proc</i> structure address in an adb register, for example <code><f</code>, and write <code>{*p_pid, <f}</code>.■ Tell adbgen that the offset is valid. The request form is <code>{OFFSETOK}</code>. This is useful after invoking another adb script which moves the adb <i>dot</i>.■ Get the size of the <i>structure</i>. The request form is <code>{SIZEOF}</code>. adbgen replaces this request with the size of the structure. This is useful in incrementing a pointer to step through an array of structures.	<code>{POINTER}</code>	pointer value in hexadecimal	<code>{LONGDEC}</code>	long value in decimal	<code>{ULONGDEC}</code>	unsigned long value in decimal	<code>{ULONGHEX}</code>	unsigned long value in hexadecimal	<code>{LONGOCT}</code>	long value in octal	<code>{ULONGOCT}</code>	unsigned long value in octal
<code>{POINTER}</code>	pointer value in hexadecimal												
<code>{LONGDEC}</code>	long value in decimal												
<code>{ULONGDEC}</code>	unsigned long value in decimal												
<code>{ULONGHEX}</code>	unsigned long value in hexadecimal												
<code>{LONGOCT}</code>	long value in octal												
<code>{ULONGOCT}</code>	unsigned long value in octal												

- Calculate an arbitrary C expression. The request form is `{EXPR, expression}`. adbggen replaces this request with the value of the expression. This is useful when more than one structure is involved in the script.
- Get the offset to the end of the structure. The request form is `{END}`. This is useful at the end of the structure to get adb to align the *dot* for printing the next structure member.

adbgen keeps track of the movement of the adb *dot* and generates adb code to move forward or backward as necessary before printing any structure member in a script. adbggen's model of the behavior of adb's *dot* is simple: it is assumed that the first line of the script is of the form *struct_address/adb text* and that subsequent lines are of the form *+/adb text*. The adb *dot* then moves in a sane fashion. adbggen does not check the script to ensure that these limitations are met. adbggen also checks the size of the structure member against the size of the adb format code and warns if they are not equal.

OPTIONS The following option is supported:

`-m model` Specifies the data type model to be used by adbggen for the macro. This affects the outcome of the *{format specifier}* requests described under DESCRIPTION and the offsets and sizes of data types. *model* can be `ilp32` or `lp64`. If the `-m` option is not given, the data type model defaults to `ilp32`.

OPERANDS The following operand is supported:

`filename.adb` Input file that contains header information, followed by a null line, the name of the structure, and finally an adb script.

EXAMPLES **EXAMPLE 1** A sample adbggen file.

For an include file `x.h` which contained

```
struct x {
    char    *x_cp;
    char    x_c;
    int     x_i;
};
```

then, an adbggen file (call it `script.adb`) to print the file `x.h` would be:

```
#include "x.h"
x
./"x_cp"16t"x_c"8t"x_i"n{x_cp, {POINTER}}{x_c,C}{x_i,D}
```

After running adbggen as follows,

```
% /usr/lib/adb/adbggen script.adb
```

the output file `script` contains:

```
./"x_cp"16t"x_c"8t"x_i"nXC3+D
```

adbgen(1M)

EXAMPLE 1 A sample adbgen file. (Continued)

For a macro generated for a 64-bit program using the lp64 data model as follows,

```
% /usr/lib/adb/adbgen/ -m lp64 script.adb
```

the output file script would contain:

```
./"x_cp"16t"x_c"8t"x_i"nJC3+D
```

To invoke the script, type:

```
example% adb program
x$<script
```

FILES /usr/platform/*platform-name*/lib/adb/*
platform-specific adb scripts for debugging the 32-bit kernel

/usr/platform/*platform-name*/lib/adb/sparcv9/*
platform-specific adb scripts for debugging the 64-bit SPARC V9 kernel

/usr/lib/adb/*
adb scripts for debugging the 32-bit kernel

/usr/lib/adb/sparcv9/*
adb scripts for debugging the 64-bit SPARC V9 kernel

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO adb(1), uname(1), kadb(1M), attributes(5)

DIAGNOSTICS Warnings are given about structure member sizes not equal to adb format items and about badly formatted requests. The C compiler complains if a structure member that does not exist is referenced. It also complains about an ampersand before array names; these complaints may be ignored.

NOTES *platform-name* can be found using the -i option of uname(1).

BUGS adb syntax is ugly; there should be a higher level interface for generating scripts.

Structure members which are bit fields cannot be handled because C will not give the address of a bit field. The address is needed to determine the offset.

NAME	addbadsec – map out defective disk blocks						
SYNOPSIS	addbadsec [-p] [-a <i>blkno</i> [<i>blkno...</i>]] [-f <i>filename</i>] <i>raw_device</i>						
DESCRIPTION	<p>addbadsec is used by the system administrator to map out bad disk blocks. Normally, these blocks are identified during surface analysis, but occasionally the disk subsystem reports unrecoverable data errors indicating a bad block. A block number reported in this way can be fed directly into addbadsec, and the block will be remapped. addbadsec will first attempt hardware remapping. This is supported on SCSI drives and takes place at the disk hardware level. If the target is an IDE drive, then software remapping is used. In order for software remapping to succeed, the partition must contain an alternate slice and there must be room in this slice to perform the mapping.</p> <p>It should be understood that bad blocks lead to data loss. Remapping a defective block does not repair a damaged file. If a bad block occurs to a disk-resident file system structure such as a superblock, the entire slice might have to be recovered from a backup.</p>						
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Adds the specified blocks to the hardware or software map. If more than one block number is specified, the entire list should be quoted and block numbers should be separated by white space. -f Adds the specified blocks to the hardware or software map. The bad blocks are listed, one per line, in the specified file. -p Causes addbadsec to print the current software map. The output shows the defective block and the assigned alternate. This option cannot be used to print the hardware map. 						
OPERANDS	<p>The following operand is supported:</p> <p><i>raw_device</i> The address of the disk drive (see FILES).</p>						
FILES	The raw device should be /dev/rdisk/c? [t?] d?p0. See disks(1M) for an explanation of SCSI and IDE device naming conventions.						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:						
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Architecture</td> <td>IA</td> </tr> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Architecture	IA	Availability	SUNWcsu

Architecture	IA						
Availability	SUNWcsu						
SEE ALSO	disks(1M), diskscan(1M), fdisk(1M), fmthard(1M), format(1M), attributes(5)						

addbadsec(1M)

NOTES | The `format(1M)` utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the `addbadsec`, `diskscan(1M)`, `fdisk(1M)`, and `fmthard(1M)` commands available for IA. To format an IDE disk, use the DOS "format" utility; however, to label, analyze, or repair IDE disks on IA systems, use the Solaris `format(1M)` utility.

NAME	add_drv – add a new device driver to the system
SYNOPSIS	add_drv [-b <i>basedir</i>] [-c <i>class_name</i>] [-i ' <i>identify_name...</i> '] [-m ' <i>permission</i> ', ' <i>...</i> '] [-n] [-f] [-v] <i>device_driver</i>
DESCRIPTION	<p>The <code>add_drv</code> command is used to inform the system about newly installed device drivers.</p> <p>Each device on the system has a name associated with it. This name is represented by the <code>name</code> property for the device. Similarly, the device may also have a list of driver names associated with it. This list is represented by the <code>compatible</code> property for the device.</p> <p>The system determines which devices will be managed by the driver being added by examining the contents of the <code>name</code> property and the <code>compatible</code> property (if it exists) on each device. If the value in the <code>name</code> property does not match the driver being added, each entry in the <code>compatible</code> property is tried, in order, until either a match occurs or there are no more entries in the <code>compatible</code> property.</p> <p>In some cases, adding a new driver may require a reconfiguration boot. See the NOTES section.</p>
OPTIONS	<p>-b <i>basedir</i> Installs the driver on the system with a root directory of <i>basedir</i> rather than installing on the system executing <code>add_drv</code>. This option is typically used in package post-installation scripts when the package is not being installed on the system executing the <code>pkgadd</code> command. The system using <i>basedir</i> as its root directory must reboot to complete the driver installation.</p> <p>-c <i>class_name</i> The driver being added to the system exports the class <i>class_name</i>.</p> <p>-i '<i>identify_name</i>' A white-space separated list of aliases for the driver <i>device_driver</i>.</p> <p>-m '<i>permission</i>' Specify the file system permissions for device nodes created by the system on behalf of <i>device_driver</i>.</p> <p>-n Do not try to load and attach <i>device_driver</i>, just modify the system configuration files for the <i>device_driver</i>.</p> <p>-f Normally if a reconfiguration boot is required to complete the configuration of the driver into the system, <code>add_drv</code> will not add the driver. The force flag forces <code>add_drv</code> to add the driver even if a reconfiguration boot is required. See the <code>-v</code> flag.</p> <p>-v The verbose flag causes <code>add_drv</code> to provide additional information regarding the success or failure of a driver's configuration into the system. See the</p>

EXAMPLES section.

EXAMPLES **EXAMPLE 1** Adding The SUNW, Example Driver to the System

The following example adds the SUNW, example driver to a 32-bit system, with an alias name of SUNW, alias. It assumes the driver has already been copied to /usr/kernel/drv.

```
example# add_drv -m '* 0666 bin bin', 'a 0644 root sys' \
-i 'SUNW,alias' SUNW,example
```

Every minor node created by the system for the SUNW, example driver will have the permission 0666, and be owned by user bin in the group bin, except for the minor device a, which will be owned by root, group sys, and have a permission of 0644.

EXAMPLE 2 Adding The Driver To The Client /export/root/sun1

The following example adds the driver to the client /export/root/sun1. The driver is installed and loaded when the client machine, sun1, is rebooted. This second example produces the same result as the first, except the changes are on the diskless client, sun1, and the client must be rebooted for the driver to be installed.

```
example# add_drv -m '* 0666 bin bin', 'a 0644 root sys' \
-i 'SUNW,alias' -b /export/root/sun1 \
SUNW,example
```

EXAMPLE 3 Adding A Driver For A Device That Is Already Managed By An Existing Driver

The following example illustrates the case where a new driver is added for a device that is already managed by an existing driver. Consider a device that is currently managed by the driver dumb_framebuffer. The name and compatible properties for this device are as follows:

```
name="display"
compatible="whizzy_framebuffer", "dumb_framebuffer"
```

If add_drv is used to add the whizzy_framebuffer driver, the following will result.

```
example# add_drv whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
```

If the -v flag is specified, the following will result.

```
example# add_drv -v whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
Driver installation failed because the following
entries in /devices would be affected:
```

```
    /devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
    (Device currently managed by driver "dumb_framebuffer")
```

EXAMPLE 3 Adding A Driver For A Device That Is Already Managed By An Existing Driver *(Continued)*

The following entries in /dev would be affected:

```
/dev/fbs/dumb_framebuffer0
```

If the -v and -f flags are specified, the driver will be added resulting in the following.

```
example# add_drv -vf whizzy_framebuffer
```

A reconfiguration boot must be performed to complete the installation of this driver.

The following entries in /devices will be affected:

```
/devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]  
(Device currently managed by driver "dumb_framebuffer")
```

The following entries in /dev will be affected:

```
/dev/fbs/dumb_framebuffer0
```

The above example is currently only relevant to devices exporting a generic device name.

EXIT STATUS

add_drv returns 0 on success and 1 on failure.

Availability	SUNWcsu

SEE ALSO `boot(1M)`, `devlinks(1M)`, `disks(1M)`, `drvconfig(1M)`, `kernel(1M)`, `modinfo(1M)`, `ports(1M)`, `rem_drv(1M)`, `tapes(1M)`, `driver.conf(4)`, `system(4)`, `attributes(5)`, `ddi_create_minor_node(9F)`

Writing Device Drivers

NOTES Aliases may require quoting (with double-quotes) if they contain numbers.

It is possible to add a driver for a device already being managed by a different driver, where the driver being added appears in the device's `compatible` list before the current driver. In such cases, a reconfiguration boot is required (see `boot(1M)` and `kernel(1M)`). After the reconfiguration boot, device nodes in `/devices`, entries in `/dev`, and references to these files may no longer be valid (see the `-v` flag). If a reconfiguration boot would be required to complete the driver installation, `add_drv` will fail unless the `-f` option is specified. See Example 3 in the `EXAMPLES` section.

BUGS `add_drv` will accept a pathname for *device_driver*. However, the kernel does not use the pathname; it only uses the final component and searches the internal driver search path for the driver. This can lead to the kernel loading a different driver than expected.

For this reason, it is not recommended that you use `add_drv` with a pathname. See `kernel(1M)` for more information on the driver search path.

A future version of `add_drv` will not support full pathnames.

NAME	admintool – system administration with a graphical user interface												
SYNOPSIS	<code>/usr/bin/admintool</code>												
DESCRIPTION	<p>admintool is a graphical user interface that enables you to accomplish several system administration tasks on a local system. Membership in the sysadmin group (gid 14) is used to restrict access to administrative tasks. Members of the sysadmin group can use admintool to create, delete, and modify local system files. Non-members have read-only permissions (where applicable).</p> <p>Help is available by using the Help button.</p> <p>admintool is not the tool for a distributed environment. It is used for local administration.</p>												
USAGE	<p>admintool allows you to do the following tasks:</p> <table> <tr> <td>Manage users</td> <td>Use admintool to add, delete, or modify user accounts. admintool makes the appropriate changes to the system's <code>/etc/passwd</code> file (see <code>passwd(4)</code>).</td> </tr> <tr> <td>Manage groups</td> <td>Use admintool to add, delete, or modify groups. admintool makes the appropriate changes to the system's <code>/etc/group</code> file (see <code>group(4)</code>).</td> </tr> <tr> <td>Manage hosts</td> <td>Use admintool to add, delete, or modify hosts. admintool makes the appropriate changes to the system's <code>/etc/hosts</code> file (see <code>hosts(4)</code>).</td> </tr> <tr> <td>Manage printers</td> <td>Use admintool to add or delete access to a printer, or to modify a system's printer access. admintool makes the appropriate changes to the system's <code>/etc/lp</code> directory.</td> </tr> <tr> <td>Manage serial port services</td> <td>Use admintool to enable or disable serial port services. admintool sets up the software services necessary to use a modem or terminal attached to a system's serial port.</td> </tr> <tr> <td>Manage software</td> <td>Use admintool to add or remove software. admintool adds software from a product CD or on a hard disk to an installed system, or removes software from an installed system.</td> </tr> </table>	Manage users	Use admintool to add, delete, or modify user accounts. admintool makes the appropriate changes to the system's <code>/etc/passwd</code> file (see <code>passwd(4)</code>).	Manage groups	Use admintool to add, delete, or modify groups. admintool makes the appropriate changes to the system's <code>/etc/group</code> file (see <code>group(4)</code>).	Manage hosts	Use admintool to add, delete, or modify hosts. admintool makes the appropriate changes to the system's <code>/etc/hosts</code> file (see <code>hosts(4)</code>).	Manage printers	Use admintool to add or delete access to a printer, or to modify a system's printer access. admintool makes the appropriate changes to the system's <code>/etc/lp</code> directory.	Manage serial port services	Use admintool to enable or disable serial port services. admintool sets up the software services necessary to use a modem or terminal attached to a system's serial port.	Manage software	Use admintool to add or remove software. admintool adds software from a product CD or on a hard disk to an installed system, or removes software from an installed system.
Manage users	Use admintool to add, delete, or modify user accounts. admintool makes the appropriate changes to the system's <code>/etc/passwd</code> file (see <code>passwd(4)</code>).												
Manage groups	Use admintool to add, delete, or modify groups. admintool makes the appropriate changes to the system's <code>/etc/group</code> file (see <code>group(4)</code>).												
Manage hosts	Use admintool to add, delete, or modify hosts. admintool makes the appropriate changes to the system's <code>/etc/hosts</code> file (see <code>hosts(4)</code>).												
Manage printers	Use admintool to add or delete access to a printer, or to modify a system's printer access. admintool makes the appropriate changes to the system's <code>/etc/lp</code> directory.												
Manage serial port services	Use admintool to enable or disable serial port services. admintool sets up the software services necessary to use a modem or terminal attached to a system's serial port.												
Manage software	Use admintool to add or remove software. admintool adds software from a product CD or on a hard disk to an installed system, or removes software from an installed system.												
EXIT STATUS	admintool terminates with exit status 0.

SEE ALSO | group(4), hosts(4), passwd(4), attributes(5)

Solaris Advanced User's Guide

WARNINGS | If you use `admintool` to add a host, your local system and your site uses a network name service such as NIS or NIS+, `admintool` host operations may not have the desired effect. This is because information in the network name service will take precedence over the information in the local `/etc/hosts` file, which is where `admintool` updates information.

NOTES | `admintool` modifies files on the local system, i.e., the system on which you are running `admintool`. `admintool` does not modify or update global networked databases such as NIS or NIS+.

NAME	afbconfig, SUNWafb_config – configure the AFB Graphics Accelerator
SYNOPSIS	<pre> /usr/sbin/afbconfig [-dev <i>device-filename</i>] [-res <i>video-mode</i> [now try] [noconfirm nocheck]] [-file machine system] [-deflinear true false] [-defoverlay true false] [-overlayorder first last] [-expvis enable disable] [-sov enable disable] [-maxwinds <i>n</i>] [-extovl enable disable] [-g <i>gamma-correction-value</i>] [-gfile <i>gamma-correction-file</i>] [-propt] [-prconf] [-defaults] /usr/sbin/afbconfig [-propt] [-prconf] /usr/sbin/afbconfig [-help] [-res ?] </pre>
DESCRIPTION	<p>afbconfig configures the AFB Graphics Accelerator and some of the X11 window system defaults for AFB.</p> <p>The following form of afbconfig stores the specified options in the OWconfig file:</p> <pre> /usr/sbin/afbconfig [-dev<i>device-filename</i>] [-res <i>video-mode</i> [now try] [noconfirm nocheck]] [-file machine system] [-deflinear true false] [-defoverlay true false] [-overlayorderfirst last] [-expvisenable disable] [-sov enable disable] [-maxwinds<i>n</i>] [-extovl enable disable] [-g<i>gamma-correction-value</i>] [-gfile<i>gamma-correction-file</i>] [-propt] [-prconf] [-defaults] </pre> <p>The options are used to initialize the AFB device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.</p> <p>The following forms of the afbconfig command invoke only the -prconf, -propt, -help, and -res ? options. None of these options update the OWconfig file.</p> <pre> /usr/sbin/afbconfig [-propt] [-prconf] /usr/sbin/afbconfig [-help] [-res ?] </pre> <p>Additionally, the following invocation of afbconfig ignores all other options:</p> <pre> /usr/sbin/afbconfig [-help] [-res ?] </pre> <p>You can only specify options for one AFB device at a time. Specifying options for multiple AFB devices requires multiple invocations of the afbconfig command.</p> <p>Only AFB-specific options can be specified through afbconfig. The normal window system options for specifying default depth, visual class and so forth are still specified as device modifiers on the openwin command line.</p> <p>You can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.</p>

afbconfig(1M)

Both of these standard `OWconfig` files can only be written by root. Consequently, the `afbconfig` program, which is owned by the root user, always runs with `setuid` root permission.

Option Defaults

For a given invocation of `afbconfig` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value. When the window system is run, if an AFB option has never been specified by way of `afbconfig`, a default value is used. The option defaults are as follows:

<code>-dev</code>	<code>/dev/fbs/afb0</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-deflinear</code>	<code>false</code>
<code>-defoverlay</code>	<code>false</code>
<code>-linearorder</code>	<code>last</code>
<code>-overlayorder</code>	<code>last</code>
<code>-expvis</code>	<code>enabled</code>
<code>-sov</code>	<code>enabled</code>
<code>-maxwids</code>	<code>32</code>
<code>-extovl</code>	<code>enabled</code>
<code>-g</code>	<code>2.22</code>

The default for the `-res` option of `none` means that when the window system is run the screen resolution is the video mode currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, `GX`) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default AFB video mode.

OPTIONS

The following options are supported:

`-defaults`

Resets all option values to their default values.

`-deflinear true | false`

AFB possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

If `true`, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the Xsun(1) `defdepth` and `defclass` options described in the OpenWindows Reference Manual).

If false, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options are chosen as the default. This option cannot be used when the `-defoverlay` option is present, because AFB doesn't possess a linear overlay visual.

`-defoverlay true | false`

The AFB provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the AFB visuals. This is called the overlay visual. Windows created in this visual do not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals damage overlay windows.

The number of colors available to the windows created using this visual depends on the settings for the `-extovl` option. If the `-extovl` is enabled, extended overlay with 256 opaque color values is available. See `-extovl`. If `-extovl` is disabled, extended overlay is not available and the visual has 256 `-maxwids`) number of opaque color values. See `-maxwids`.

If the value of `-defoverlay` is `true`, the overlay visual is made the default visual. If the value of `-defoverlay` is `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `def`, `depth`, and `defclass`, are chosen as the default visual. See the OpenWindows Reference Manual.

Whenever the `defoverlay true` option is used, the default depth and class specified on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message is printed and the `-defoverlay` option is treated as `false`.

The `-defoverlay` option can not be used when the `-deflinear` option specified, because AFB doesn't possess a linear overlay visual.

`-dev device-filename`

Specifies the AFB special file. The default is `/dev/fbs/afb0`.

`-expvis enable | disable`

If enabled, activates OpenGL Visual Expansion. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor and so forth) are in the screen visual list.

`-extovl enable | disable`

If enabled, makes extended overlay available. The overlay visuals have 256 opaque colors. The SOV visuals have 255 opaque colors and 1 transparent color.

This option also enables hardware supported transparency, thus provides better performance for windows using the SOV visuals.

`-file machine | system`

Specifies which `OWconfig` file to update. If `machine` is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is used. If `system` specifies the global `OWconfig` file in the `/usr/openwin` directory tree. If the specified file does not exist, it is created.

afbconfig(1M)

`-g gamma-correction value`

Allows changing the gamma correction value. All linear visuals provide gamma correction. By default, the *gamma-correction-value* is 2.22. Any value less than 0 is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by `XSolarisGetVisualGamma(3)`. See `XSolarisGetVisualGamma(3)` for a description of that function.

This option can be used while the window system is running. Changing the gamma correction value affects all the windows being displayed using the linear visuals.

`-gfile gamma-correction-file`

Loads the gamma correction table from the specified file (*gamma-correction-file*). This file should be formatted to provide the gamma correction values for R, G and B channels on each line. Each of these values should be in hexadecimal format and separated from each other by at least one space. *gamma-correction-file* should also provide 256 such triplets.

An example of a *gamma-correction-file* follows.

```
0x00 0x00 0x00
0x01 0x01 0x01
0x02 0x02 0x02
...
...
0xff 0xff 0xff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction affects all the windows being displayed using the linear visuals. When gamma correction is being done using user specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

`-help`

Prints a list of the `afbconfig` command line options, along with a brief explanation of each.

`-linearorder first | last`

If `first`, linear visuals come before their non-linear counterparts on the X11 screen visual list for the AFB screen. If `last`, the nonlinear visuals come before the linear ones.

`-maxwids n`

Specifies the maximum number of AFB X channel pixel values that are reserved for use as window IDs (WIDs). The remainder of the pixel values in overlay colormaps are used for normal X11 opaque color pixels. The reserved WIDs are allocated on a first-come first-serve basis by 3D graphics windows (such as XGL), MBX windows, and windows that have a non-default visual. The X channel codes 0 to (255 - *n*) are opaque color pixels. The X channel codes (255 - *n* + 1) to 255 are reserved for use as WIDs. Legal values are 1, 2, 4, 8, 16, 32, and 64.

This option is available only if the `-extovl` is disabled.

`-overlayorder first | last`

If `first`, the depth 8 PseudoColor Overlay visual comes before the non-overlay visual on the X11 screen visual list for the AFB screen. If `last`, the non-overlay visual comes before the overlay one.

`-propt`

Prints the current values of all AFB options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to `afbconfig` completes.

The following is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/afb0 ---
OWconfig: machine
Video Mode: 1280x1024x76
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
                  Overlay Visuals are last
OpenGL Visual Expansion: enabled
Server Overlay Visuals: enabled
Extended Overlay: enabled
Underlay WIDs: 64 (not configurable)
Overlay WIDs: 4 (not configurable)
Gamma Correction Value: 2.220
Gamma Correction Table: Available
```

`-prconf`

Prints the AFB hardware configuration.

The following is a typical display:

```
--- Hardware Configuration for /dev/fbs/afb0 ---
Type: double-buffered AFB with Z-buffer
Board: rev 0 (Horizontal)
Number of Floats: 6
PROM Information: @(#)afb.fth x.xx xx/xx/xx
AFB ID: 0x101df06d
DAC: Brooktree 9070, version 1 (Pac2)
3DRAM: Mitsubishi 130a, version x
EDID Data: Available - EDID version 1 revision x
Monitor Sense ID: 4 (Sun 37x29cm RGB color monitor)
Monitor possible resolutions: 1024x768x77, 1024x800x84, 1
                              1152x900x76, 1280x1024x67, 1280x1024x76, 960x680xx108s
Current resolution setting: 1280x1024x76
```

`-sov enable | disable`

If enabled, the root window's `SERVER_OVERLAY_VISUALS` property are advertised. SOV visuals are exported and their transparent types, values and layers can be retrieved through this property. If disabled, the `SERVER_OVERLAY_VISUALS` property are not defined and SOV visuals are not exported.

afbconfig(1M)

`-res video-mode [now | try [noconfirm | nocheck]]`

Specifies the video mode used to drive the monitor connected to the specified AFB device.

The format of these built-in video modes is: *widthxheightxrate*, where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

The *s* suffix of `960x680x112s` and `960x680x108s` means that these are stereo video modes. The *i* suffix of `640x480x60i` and `768x575x50i` designates interlaced video timing. If absent, non-interlaced timing is used.

As a convenience, the `-res` also accepts formats with an at sign (@) in front of the refresh rate instead of *n*, (`1280x1024@76`). Some video-modes, supported by AFB, may not be supported by the monitor. The list of video-modes supported by the AFB device and the monitor can be obtained by running `afbconfig` with the `-res ?` option (the third form shown SYNOPSIS).

A list of all possible video-modes supported on AFB follows:

```
1024x768x60
1024x768x70
1024x768x75
1024x768x77
1024x800x84
1152x900x66
1152x900x76
1280x800x76
1280x1024x60
1280x1024x67
1280x1024x76
960x680x112s (Stereo)
960x680x108s (Stereo)
640x480x60
640x480x60i (Interlaced)
768x575x50i (Interlaced)
```

For convenience, some of the video-modes supported on the AFB have *symbolic names* defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to the `-res` option. The meaning of the symbolic name `none` is that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

A list of symbolic names for video-modes supported on AFB follows:

Name	Corresponding Video Mode
<code>svga</code>	<code>1024x768x60</code>
<code>1152</code>	<code>1152x900x76</code>
<code>1280</code>	<code>1280x1024x76</code>

stereo 960x680x112s
 ntsc 640x480x60i
 pal 768x575x50i
 none (see text above)

The `-res` option also accepts the additional, optional arguments immediately following the video mode specification. Any or all of the following arguments can be specified:

- `noconfirm` Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `afbconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `afbconfig` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `afbconfig` is being run from a shell script.
- `nocheck` If present, the normal error checking based on the monitor sense code is suspended. The video mode specified by the user is accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the AFB device). Use of this option implies `noconfirm` well.
- `now` Updates the video mode in the `OWconfig` file, and immediately programs the AFB device to display this video mode. This is useful for changing the video mode before starting the window system.
- It is inadvisable to use this argument with `afbconfig` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `afbconfig` with the `now` argument, first bring the window system down. If the `now` argument is used within a window system session, the video mode is changed immediately, but the width and height of the affected screen won't change until the window system is exited and re-entered again. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

afbconfig(1M)

try

If present, the specified video mode is programmed on a trial basis. The user is asked to confirm the video mode by typing `y` within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than `y` or Return is considered a `no`. The previous video mode is restored and `afbconfig` does not change the video mode in the `OWconfig` file (other options specified still take effect). If a Return is typed, the user is prompted for a `yes` or `no` answer on whether to keep the new video mode. This option implies the `now` argument (see the warning note on the `now` argument).

EXAMPLES

EXAMPLE 1 Switching the monitor type

The following example switches the monitor type to a resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/sbin/afbconfig -res 1280x1024x76
```

NAME	answerbook2_admin – bring up AnswerBook2 administration tool GUI				
SYNOPSIS	<code>/usr/dt/bin/answerbook2_admin [-h]</code>				
DESCRIPTION	<p>answerbook2_admin brings up the default web browser showing the administration interface for the local AnswerBook2 server. The AnswerBook2 administration tool based on the Web browser provides the same functionality as the ab2admin(1M) command-line administration tool.</p> <p>This functionality is also accessible through the AnswerBook2 Admin option within the System_Admin subset of the Application Manager function on the CDE front panel Applications menu.</p>				
OPTIONS	<p>The following option is supported:</p> <p>-h Displays a usage statement.</p>				
USAGE	At startup time, answerbook2_admin starts up the default web browser (for example, HotJava or Netscape) and displays the URL specified for administering the local AnswerBook2 server (<code>http://localhost:8888</code>). If the user has set up administration access control, the web browser prompts for a valid administrator login and password for this document server before displaying the administration tool.				
FILES	<p><code>/usr/lib/ab2/dweb/data/config/admin_passwd</code> File containing <i>username: password</i></p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWab2m</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWab2m
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWab2m				
SEE ALSO	ab2admin(1M), attributes(5)				
NOTES	Once there is an open web browser and access to the AnswerBook2 Administration tool, use its online Help system to find out more about administering the AnswerBook2 server.				

apache(1M)

NAME	apache – Apache hypertext transfer protocol server overview																						
DESCRIPTION	apache consists of a main server daemon, loadable server modules, some additional support utilities, configuration files, and documentation.																						
FILES	<p>The apache HTTPD server is integrated with Solaris.</p> <p>The following files specify the installation locations for apache:</p> <table><tr><td>/etc/apache</td><td>Contains server configuration files.</td></tr><tr><td></td><td>A newly-installed server must be manually configured before use. Typically this involves copying <code>httpd.conf-example</code> to the <code>httpd.conf</code> file and making local configuration adjustments.</td></tr><tr><td>/usr/apache/bin</td><td>Contains the <code>httpd</code> executable as well as other utility programs.</td></tr><tr><td>/usr/apache/htdocs</td><td>Contains the Apache manual in HTML format. This documentation is accessible by way of a link on the server test page that gets installed upon fresh installation.</td></tr><tr><td>/usr/apache/include</td><td>Contains the Apache header files, which are needed for building various optional server extensions with <code>apxs(8)</code></td></tr><tr><td>/usr/apache/jserv</td><td>Contains documentation for the <code>mod_jserv</code> java servlet module. Documentation can be read with a web browser using the url: <code>file:/usr/apache/jserv/docs/index.html</code></td></tr><tr><td>/usr/apache/libexec</td><td>Contains loadable modules (DSOs) supplied with the server. Any modules which are added using <code>apxs(8)</code> are also copied into this directory.</td></tr><tr><td>/usr/apache/man</td><td>Contains man pages for the server, utility programs, and <code>mod_perl</code>. Add this directory to your <code>MANPATH</code> to read the Apache man pages. See <code>NOTES</code>.</td></tr><tr><td>/usr/apache/perl5</td><td>Contains the modules and library files used by the <code>mod_perl</code> extension to Apache.</td></tr><tr><td>/var/apache/cgi-bin</td><td>Default location for the CGI scripts. This can be changed by altering the <code>httpd.conf</code> file and restarting the server.</td></tr><tr><td>/var/apache/htdocs</td><td>Default document root.</td></tr></table>	/etc/apache	Contains server configuration files.		A newly-installed server must be manually configured before use. Typically this involves copying <code>httpd.conf-example</code> to the <code>httpd.conf</code> file and making local configuration adjustments.	/usr/apache/bin	Contains the <code>httpd</code> executable as well as other utility programs.	/usr/apache/htdocs	Contains the Apache manual in HTML format. /usr/apache/perl5	Contains the modules and library files used by the <code>mod_perl</code> extension to Apache.																						
/var/apache/cgi-bin	Default location for the CGI scripts. This can be changed by altering the <code>httpd.conf</code> file and restarting the server.																						
/var/apache/htdocs	Default document root.																						

This can be changed by altering the `httpd.conf` file and restarting the server.

`/var/apache/icons` Icons used by the server.

This normally shouldn't need to be changed.

`/var/apache/logs` Contains server log files.

The formats, names, and locations of the files in this directory can be altered by various configuration directives in the `httpd.conf` file.

`/var/apache/proxy` Directory used to cache pages if the caching feature of `mod_proxy` is enabled in the `httpd.conf` file.

The location of the cache can also be changed by changing the proxy configuration in the `httpd.conf` file.

NOTES In addition to the documentation and man pages included with Solaris, more information is available at <http://www.apache.org>

The Apache man pages are provided with the programming modules. To view the manual pages for the Apache modules with the `man` command, add `/usr/apache/man` to the `MANPATH` environment variable. See `man(1)` for more information. Running `catman(1M)` on the Apache manual pages is not supported.

arp(1M)

NAME	arp – address resolution display and control								
SYNOPSIS	arp <i>hostname</i> arp -a [-n] arp -d <i>hostname</i> arp -f <i>filename</i> arp -s <i>hostname ether_address</i> [temp] [pub] [trail]								
DESCRIPTION	<p>The arp program displays and modifies the Internet-to-Ethernet address translation tables used by the address resolution protocol (see arp(7P)).</p> <p>With no flags, the program displays the current ARP entry for <i>hostname</i>. The host may be specified by name or by number, using Internet dot notation.</p>								
OPTIONS	<p>-a Display all of the current ARP entries. The definition for the flags in the table are:</p> <table><tr><td>P</td><td>Publish; includes IP address for the machine and the addresses that have explicitly been added by the -s option. ARP will respond to ARP requests for this address.</td></tr><tr><td>S</td><td>Static; not learned for the ARP protocol.</td></tr><tr><td>U</td><td>Unresolved; waiting for ARP response.</td></tr><tr><td>M</td><td>Mapping; only used for the multicast entry for 224.0.0.0</td></tr></table> <p>You can use the -n option with the -a option to disable the automatic numeric IP address-to-name translation. Use arp -an or arp -na to display numeric IP addresses.</p> <p>-d Delete an entry for the host called <i>hostname</i>. This option may only be used by the super-user.</p> <p>-f Read the file named <i>filename</i> and set multiple entries in the ARP tables. Entries in the file should be of the form</p> <p><i>hostname ether_address</i> [temp] [pub] [trail]</p> <p>(see option -s for argument definitions).</p> <p>-s Create an ARP entry for the host called <i>hostname</i> with the Ethernet address <i>ether_address</i>. The Ethernet address is given as six hexadecimal bytes separated by colons. The entry will be permanent unless the word <i>temp</i> is given in the command. If the word <i>pub</i> is given, the entry will be published. For instance, this system will respond to ARP requests for <i>hostname</i> even though the hostname is not its own. The word <i>trail</i> indicates that trailer encapsulations may be sent to this host. arp -s can be used for a limited form of proxy ARP when a host on one of the directly</p>	P	Publish; includes IP address for the machine and the addresses that have explicitly been added by the -s option. ARP will respond to ARP requests for this address.	S	Static; not learned for the ARP protocol.	U	Unresolved; waiting for ARP response.	M	Mapping; only used for the multicast entry for 224.0.0.0
P	Publish; includes IP address for the machine and the addresses that have explicitly been added by the -s option. ARP will respond to ARP requests for this address.								
S	Static; not learned for the ARP protocol.								
U	Unresolved; waiting for ARP response.								
M	Mapping; only used for the multicast entry for 224.0.0.0								

arp(1M)

attached networks is not physically present on the subnet. Another machine can then be configured to respond to ARP requests using `arp -s`. This is useful in certain SLIP or PPP configurations.

aset(1M)

NAME	aset – monitors or restricts accesses to system files and directories		
SYNOPSIS	aset [-p] [-d <i>aset_dir</i>] [-l <i>sec_level</i>] [-n <i>user@host</i>] [-u <i>userlist_file</i>]		
DESCRIPTION	<p>The Automated Security Enhancement Tool (ASET) is a set of administrative utilities that can improve system security by allowing the system administrators to check the settings of system files, including both the attributes (permissions, ownership, etc.) and the contents of the system files. It warns the users of potential security problems and, where appropriate, sets the system files automatically according to the security level specified.</p> <p>The security level for <code>aset</code> can be specified by setting the <code>-l</code> command line option or the <code>ASETSECLEVEL</code> environment variable to be one of 3 values: <code>low</code>, <code>med</code>, or <code>high</code>. All the functionality operates based on the value of the security level.</p> <p>At the <code>low</code> level, <code>aset</code> performs a number of checks and reports any potential security weaknesses.</p> <p>At the <code>med</code> level, <code>aset</code> modifies some of the settings of system files and parameters, thus restricting system access, to reduce the risks from security attacks. Again it will report the security weaknesses and the modifications performed to restrict access. This does not affect the operations of system services. All the system applications and commands will maintain all of their original functionality.</p> <p>At the <code>high</code> level, further restrictions are made to system access, rendering a very defensive system. Security practices which are not normally required are included. Many system files and parameters settings are modified to minimum access permissions. At this level, security is the foremost concern, higher than any other considerations that affect system behavior. The vast majority of system applications and commands will maintain their functionality, although there may be a few that exhibit behaviors that are not familiar in normal system environment.</p> <p>More exact definitions of these levels (what exactly <code>aset</code> will do at each level) can be found in the administrator manual. The <code>asetenv(4)</code> file and the <i>master files</i> (see <code>asetmasters(4)</code>) determine to a large extent what <code>aset</code> performs at each level, and can be used by the experienced administrators to redefine the definitions of the levels to suit their particular needs. These files are provided by default to fit most security conscious environments and in most cases provide adequate security safeguards without modification. They are, however, designed in a way that can be easily edited by experienced administrators with specific needs.</p> <p><code>aset</code> can be periodically activated at the specified security level with default definitions using the <code>-p</code> option. <code>aset</code> will be automatically activated at a frequency specified by the administrator starting from a designated future time (see <code>asetenv(4)</code>). Without the <code>-p</code> option, <code>aset</code> will operate only once immediately.</p>		
OPTIONS	<p>The following options are supported:</p> <table><tr><td><code>-d <i>aset_dir</i></code></td><td>Specifies a working directory other than <code>/usr/aset</code> for ASET. <code>/usr/aset</code> is the default working directory.</td></tr></table>	<code>-d <i>aset_dir</i></code>	Specifies a working directory other than <code>/usr/aset</code> for ASET. <code>/usr/aset</code> is the default working directory.
<code>-d <i>aset_dir</i></code>	Specifies a working directory other than <code>/usr/aset</code> for ASET. <code>/usr/aset</code> is the default working directory.		

	It is where ASET is installed, and is the <i>root</i> directory of all ASET utilities and data files. If another directory is to be used as the ASET working directory you can either define it with the <i>-d</i> option, or by setting the <i>ASETDIR</i> environment variable before invoking <i>aset</i> . The command line option, if specified, overwrites the environment variable.
<i>-l sec_level</i>	Specifies a security level (<i>low</i> , <i>med</i> , or <i>high</i>) for <i>aset</i> to operate at. The default level is <i>low</i> . Each security level is explained in detail above. The level can also be specified by setting the <i>ASETSECLEVEL</i> environment variable before invoking <i>aset</i> . The command line option, if specified, overwrites the environment variable.
<i>-n user@host</i>	Notifies <i>user</i> at machine <i>host</i> . Send the output of <i>aset</i> to <i>user</i> through e-mail. If this option is not specified, the output is sent to the standard output. Note that this is not the reports of ASET, but rather an execution log including error messages if there are any. This output is typically fairly brief. The actual reports of ASET are found in the <i>/usr/aset/reports/latest</i> directory. See the <i>-d</i> option.
<i>-p</i>	Schedules <i>aset</i> to be executed periodically. This adds an entry for <i>aset</i> in the <i>/etc/crontab</i> file. The <i>PERIODIC_SCHEDULE</i> environment variable in the <i>/usr/aset/asetenv</i> file is used to define the time for execution. See <i>crontab(1)</i> and <i>asetenv(4)</i> . If a <i>crontab(1)</i> entry for <i>aset</i> already exists, a warning is produced in the execution log.
<i>-u userlist_file</i>	Specifies a file containing a list of users. <i>aset</i> will perform environment checks (for example, <i>UMASK</i> and <i>PATH</i> variables) on these users. By default, <i>aset</i> only checks for <i>root</i> . <i>userlist_file</i> is an ASCII text file. Each entry in the file is a line that contains only one user name (login name).

USAGE The following paragraphs discuss the features provided by ASET. Hereafter, each feature is referred to as a *task*. The first task, *tune*, is intended to be executed only once per installation of ASET. The other tasks are intended to be executed periodically at the specified frequency.

tune Task This task is used to tighten system file permissions. In standard releases, system files or directories have permissions defined to maximize open information sharing. In a more security conscious environment, the administrator may want to redefine these permission settings to more restrictive values. *aset* allows resetting of these

aset(1M)

permissions, based on the specified security level. Generally, at the low level the permissions are set to what they should be as released. At the medium level the permissions are tightened to ensure reasonable security that is adequate for most environments. At the high level they are further tightened to very restrictive access. The system files affected and the respective restrictions at different levels are configurable, using the `tune.low`, `tune.med`, and `tune.high` files. See `asetmasters(4)`.

cklist Task

System directories that contain relatively static files (that is, their contents and attributes do not change frequently) are examined and compared with a master description file. The `/usr/aset/masters/cklist.level` files are automatically generated the first time the `cklist` task is executed. See `asetenv(4)`. Any discrepancy found is reported. The directories and files are compared based on the following:

- owner and group
- permission bits
- size and checksum (if file)
- number of links
- last modification time

The lists of directories to check are defined in `asetenv(4)`, based on the specified security level, and are configurable using the `CKLISTPATH_LOW`, `CKLISTPATH_MED`, and `CKLISTPATH_HIGH` environment variables. Typically, the lower level lists are subsets of the higher level lists.

usrgrp Task

`aset` checks the consistency and integrity of user accounts and groups as defined in the `passwd` and `group` databases, respectively. Any potential problems are reported. Potential problems for the `passwd` file include:

- `passwd` file entries are not in the correct format.
- User accounts without a password.
- Duplicate user names.
- Duplicate user IDs. Duplicate user IDs are reported unless allowed by the `uid_alias` file. See `asetmasters(4)`.
- Invalid login directories.
- If C2 is enabled, check C2 hidden `passwd` format.

Potential problems for the `group` file include:

- Group file entries not in the right format.
- Duplicate group names.
- Duplicate group IDs.
- Null group passwords.

`aset` checks the local `passwd` file. If the `YPCHECK` environment variable is set to `true`, `aset` also checks the NIS `passwd` files. See `asetenv(4)`. Problems in the NIS

passwd file are only reported and not corrected automatically. The checking is done for all three security levels except where noted.

sysconf Task

aset checks various system configuration tables, most of which are in the /etc directory. aset checks and makes appropriate corrections for each system table at all three levels except where noted. The following discussion assumes familiarity with the various system tables. See the manual pages for these tables for further details.

The operations for each system table are:

/etc/hosts.equiv	<p>The default file contains a single "+" line, thus making every known host a trusted host, which is not advised for system security. aset performs the following operations:</p> <p>Low Warns the administrators about the "+" line.</p> <p>Medium</p> <p>High Warns about and deletes that entry.</p>
/etc/inetd.conf	<p>The following entries for system daemons are checked for possible weaknesses.</p> <p>tftp(1) does not do any authentication. aset ensures that in.tftpd(1M) is started in the right directory on the server and is not running on clients. At the low level, it gives warnings if the mentioned condition is not true. At the medium and high levels it gives warnings, and changes (if necessary) the in.tftpd entry to include the -s /tftpboot option after ensuring the directory /tftpboot exists.</p> <p>ps(1) and netstat(1M) provide valuable information to potential system crackers. These are disabled when aset is executed at a high security level.</p> <p>rexid is also known to have poor authentication mechanism. aset disables rexd for medium and high security levels by commenting out this entry. If rexd is activated with the -s (secure RPC) option, it is not disabled.</p>
/etc/aliases	<p>The decode alias of UUCP is a potential security weakness. aset disables the alias for medium and high security levels by commenting out this entry.</p>
/etc/default/login	<p>The CONSOLE= line is checked to allow root login only at a specific terminal depending on the security level:</p> <p>Low No action taken.</p>

aset(1M)

		Medium
		High Adds the following line to the file: CONSOLE=/dev/console
	/etc/vfstab	aset checks for world-readable or writeable device files for mounted file systems.
	/etc/dfs/dfstab	aset checks for file systems that are exported without any restrictions.
	/etc/ftpusers	At high security level, aset ensures root is in /etc/ftpusers (create if necessary), thus disallowing ftp(1) to be used as root.
	/var/adm/utmpx	aset makes these files not world-writeable for the high level (some applications may not run properly with this setting.)
	/.rhosts	The usage of a .rhosts file for the entire system is not advised. aset gives warnings for the low level and moves it to /.rhosts.bak for levels medium and high.
env Task	aset checks critical environment variables for root and users specified with the -u <i>userlist_file</i> option by parsing the /.profile, /.login, and /.cshrc files. This task checks the PATH variable to ensure that it does not contain '.' as a directory, which makes an easy target for <i>trojan horse</i> attacks. It also checks that the directories in the PATH variable are not world-writeable. Furthermore, it checks the UMASK variable to ensure files are not created as readable or writeable by world. Any problems found by these checks are reported.	
eeeprom Task	Newer versions of the EEPROM allow specification of a <i>secure</i> parameter. See eeprom(1M). aset recommends that the administrator sets the parameter to <i>command</i> for the medium level and to <i>full</i> for the high level. It gives warnings if it detects the parameter is not set adequately.	
firewall Task	At the high security level, aset takes proper measures such that the system can be safely used as a firewall in a network. This mainly involves disabling IP packets forwarding and making routing information invisible. Firewalling provides protection against external access to the network.	
ENVIRONMENT VARIABLES	ASETDIR	Specify ASET's working directory. Defaults to /usr/aset.
	ASETSECLEVEL	Specify ASET's security level. Defaults to low.
	TASKS	Specify the tasks to be executed by aset. Defaults to all tasks.
FILES	/usr/aset/reports	directory of ASET reports

aset.restore(1M)

NAME	aset.restore – restores system files to their content before ASET is installed				
SYNOPSIS	aset.restore [-d <i>aset_dir</i>]				
DESCRIPTION	<p>aset.restore restores system files that are affected by the Automated Security Enhancement Tool (ASET) to their pre-ASET content. When ASET is executed for the first time, it saves and archives the original system files in the /usr/aset/archives directory. The aset.restore utility reinstates these files. It also deschedules ASET, if it is currently scheduled for periodic execution. See asetenv(4).</p> <p>If you have made changes to system files after running ASET, these changes are lost when you run aset.restore. If you want to be absolutely sure that you keep the existing system state, it is recommended that you back-up your system before using aset.restore.</p> <p>You should use aset.restore, under the following circumstances:</p> <p>You want to remove ASET permanently and restore the original system (if you want to deactivate ASET, you can remove it from scheduling).</p> <p>You are unfamiliar with ASET and want to experiment with it. You can use aset.restore to restore the original system state.</p> <p>When some major system functionality is not working properly and you suspect that ASET is causing the problem; you may want to restore the system to see if the problem persists without ASET.</p> <p>aset.restore requires root privileges to execute.</p>				
OPTIONS	<p>The following options are supported:</p> <p>-d <i>aset_dir</i> Specify the working directory for ASET. By default, this directory is /usr/aset. With this option the archives directory will be located under <i>aset_dir</i>.</p>				
FILES	/usr/aset/archives archive of system files prior to executing aset

NAME	audit – control the behavior of the audit daemon				
SYNOPSIS	audit -n -s -t				
DESCRIPTION	The <code>audit</code> command is the general administrator’s interface to maintaining the audit trail. The audit daemon may be notified to read the contents of the <code>audit_control(4)</code> file and re-initialize the current audit directory to the first directory listed in the <code>audit_control</code> file or to open a new audit file in the current audit directory specified in the <code>audit_control</code> file as last read by the audit daemon. The audit daemon may also be signaled to close the audit trail and disable auditing.				
OPTIONS	<p>-n Signal audit daemon to close the current audit file and open a new audit file in the current audit directory.</p> <p>-s Signal audit daemon to read audit control file. The audit daemon stores the information internally.</p> <p>-t Signal audit daemon to close the current audit trail file, disable auditing and die.</p>				
DIAGNOSTICS	The <code>audit</code> command will exit with 0 upon success and a positive integer upon failure.				
FILES	<p>/etc/security/audit_user</p> <p>/etc/security/audit_control</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

SEE ALSO	<code>bsmconv(1M)</code> , <code>praudit(1M)</code> , <code>audit(2)</code> , <code>audit_control(4)</code> , <code>audit_user(4)</code> , <code>attributes(5)</code>				
NOTES	<p>The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See <code>bsmconv(1M)</code> for more information.</p> <p>This command does not modify a process’s preselection mask. It only affects which audit directories are used for audit data storage and to specify the minimum size free.</p>				

auditconfig(1M)

NAME	auditconfig – configure auditing
SYNOPSIS	auditconfig <i>option...</i>
DESCRIPTION	<p>auditconfig provides a command line interface to get and set kernel audit parameters.</p> <p>The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.</p>
OPTIONS	<p>-aconf Set the non-attributable audit mask from the audit_control(4) file. For example:</p> <pre># auditconfig -aconf Configured non-attributable events.</pre> <p>-audit event sorf retval string This command constructs an audit record for audit event <i>event</i> using the process's audit characteristics containing a text token <i>string</i>. The return token is constructed from the <i>sorf</i> (success/failure flag) and the <i>retval</i> (return value). The event is type <i>char*</i>, the <i>sorf</i> is 0/1 for success/failure, <i>retval</i> is an errno value, <i>string</i> is type <i>*char</i>. This command is useful for constructing an audit record with a shell script. An example of this option:</p> <pre># auditconfig -audit AUE_ftpd 0 0 "test string" # audit record from audit trail: header,76,2,ftp access,,Fri Dec 08 08:44:02 2000, + 669 msec subject,abc,root,other,root,other,104449,102336,235 197121 elbow text,test string return,success,0</pre> <p>-chkaconf Checks the configuration of the non-attributable events set in the kernel against the entries in audit_control(4). If the runtime class mask of a kernel audit event does not match the configured class mask, a mismatch is reported.</p> <p>-chkconf Check the configuration of kernel audit event to class mappings. If the runtime class mask of a kernel audit event does not match the configured class mask, a mismatch is reported.</p> <p>-conf Configure kernel audit event to class mappings. Runtime class mappings are changed to match those in the audit event to class database file.</p> <p>-getasid Prints the audit session ID of the current process. For example:</p> <pre># auditconfig -getasid audit session id = 102336</pre> <p>-getaudit Returns the audit characteristics of the current process.</p>

```
# auditconfig -getaudit
audit id = abc(666)
process preselection mask = lo(0x1000,0x1000)
terminal id (maj,min,host) = 235,197121,elbow(129.146.89.77)
audit session id = 102336
```

-getaudit

Prints the audit ID of the current process. For example:

```
# auditconfig -getaudit
audit id = abc(666)
```

-getcar

Prints current active root location (anchored from root at system boot). For example:

```
# auditconfig -getcar
current active root = /
```

-getclass *event*

Display the preselection mask associated with the specified kernel audit event. *event* is the kernel event number or event name.

-getcond

Display the kernel audit condition. The condition displayed is the literal string *auditing*, meaning auditing is enabled and turned on (the kernel audit module is constructing and queuing audit records); *noaudit*, meaning auditing is enabled but turned off (the kernel audit module is not constructing and queuing audit records); *disabled*, meaning that the audit module has not been enabled; or *nospace*, meaning there is no space for saving audit records. See [auditon\(2\)](#) and [auditd\(1M\)](#) for further information.

-getestate *event*

For the specified event (string or event number), print out classes *event* has been assigned. For example:

```
# auditconfig -getestate 20
audit class mask for event AUE_REBOOT(20) = 0x800
# auditconfig -getestate AUE_RENAME
audit class mask for event AUE_RENAME(42) = 0x30
```

-getfsize

Return the maximum audit file size in bytes and the current size of the audit file in bytes.

-getkaudit

Get audit characteristics of machine. For example:

```
# auditconfig -getkaudit
audit id = unknown(-2)
process preselection mask = lo,na(0x1400,0x1400)
terminal id (maj,min,host) = 0,0,(0.0.0.0)
audit session id = 0
```

-getkmask

Get non-attributable pre-selection mask for machine. For example:

auditconfig(1M)

```
# auditconfig -getkmask
audit flags for non-attributable events = lo,na(0x1400,0x1400)

-getpinfo pid
  Display the audit ID, preselection mask, terminal ID, and audit session ID for the
  specified process.

-getpolicy
  Display the kernel audit policy.

-getcwd
  Prints current working directory (anchored from root at system boot). For example:

  # cd /usr/tmp
  # auditconfig -getcwd
  current working directory = /var/tmp

-getqbufsz
  Get audit queue write buffer size. For example:

  # auditconfig -getqbufsz
  audit queue buffer size (bytes) = 1024

-getqctrl
  Get audit queue write buffer size, audit queue hiwater mark, audit queue
  lowater mark, audit queue prod interval (ticks).

  # auditconfig -getqctrl
  audit queue hiwater mark (records) = 100
  audit queue lowater mark (records) = 10
  audit queue buffer size (bytes) = 1024
  audit queue delay (ticks) = 20

-getqdelay
  Get interval at which audit queue is prodded to start output. For example:

  # auditconfig -getqdelay
  audit queue delay (ticks) = 20

-getqhiwater
  Get high water point in undelivered audit records when audit generation will
  block. For example:

  # ./auditconfig -getqhiwater
  audit queue hiwater mark (records) = 100

-getqlowater
  Get low water point in undelivered audit records where blocked processes will
  resume. For example:

  # auditconfig -getqlowater
  audit queue lowater mark (records) = 10

-getstat
  Print current audit statistics information. For example:

  # auditconfig -getstat
  gen nona kern aud ctl enq wrtn wblk rblk drop tot mem
```

```

910 1 725 184 0 910 910 0 231 0 88 48

```

-gettid
Print audit terminal ID for current process. For example:

```

# auditconfig -gettid
terminal id (maj,min,host) = 235,197121,elbow(129.146.89.77)

```

-lsevent
Display the currently configured (runtime) kernel and user level audit event information.

-lspolicy
Display the kernel audit policies with a description of each policy.

-setasid *session-ID* [*cmd*]
Execute shell or *cmd* with specified *session-ID*. For example:

```

# ./auditconfig -setasid 2000 /bin/ksh
#
# ./auditconfig -getpinfo 104485
audit id = abc(666)
process preselection mask = 1o(0x1000,0x1000)
terminal id (maj,min,host) = 235,197121,elbow(129.146.89.77)
audit session id = 2000

```

-setaudit *audit-ID* *preselect_flags* *term-ID* *session-ID* [*cmd*]
Execute shell or *cmd* with the specified audit characteristics.

-setaudit *audit-ID* [*cmd*]
Execute shell or *cmd* with the specified *audit-ID*.

-setclass *event* *audit_flag* [*audit_flag* . . .]
Map the kernel event *event* to the classes specified by *audit_flags*. *event* is an event number or name. An *audit_flag* is a two character string representing an audit class. See `audit_control(4)` for further information.

-setcond [*auditing* | *noaudit* | *nospace*]
Set the kernel audit condition to the *condition* specified where *condition* is the literal string *auditing*, indicating auditing should be enabled; *noaudit*, indicating auditing should be disabled; or *nospace*, which forces a no-space condition. (See `-getcond`, above.)

-setfsize *size*
Set the maximum size of an audit file to *size* bytes. When the size limit is reached, the audit file is closed and another is started.

-setkaudit *IP-address_type* *IP_address*
Set IP address of machine to specified values. *IP-address_type* is *ipv6* or *ipv4*.

-setkmask *audit_flags*
Set non-attributes selection flags of machine.

auditconfig(1M)

- setpmask *pid flags*
Set the preselection mask of the specified process. *flags* is the ASCII representation of the flags similar to that in `audit_control(4)`.
- setpolicy [+|-]*policy_flag*[,*policy_flag* ...]
Set the kernel audit policy. A policy *policy_flag* is literal strings that denotes an audit policy. A prefix of + adds the policies specified to the current audit policies. A prefix of - removes the policies specified from the current audit policies. The following are the valid policy flag strings (`auditconfig -lspolicy` also lists the current valid audit policy flag strings):
 - all Include all policies.
 - arge Include the `execv(2)` system call environment arguments to the audit record. This information is not included by default.
 - argv Include the `execv(2)` system call parameter arguments to the audit record. This information is not included by default.
 - cnt Do not suspend processes when audit resources are exhausted. Instead, drop audit records and keep a count of the number of records dropped. By default, process are suspended until audit resources become available.
 - group Include the supplementary group token in audit records. By default, the group token is not included.
 - none Include no policies.
 - path Add secondary path tokens to audit record. These are typically the pathnames of dynamically linked shared libraries or command interpreters for shell scripts. By default, they are not included.
 - trail Include the trailer token in every audit record. By default, the trailer token is not included.
 - seq Include the sequence token as part of every audit record. By default, the sequence token is not included. The sequence token attaches a sequence number to every audit record.
- setqbufsz *buffer_size*
Set the audit queue write buffer size (bytes).
- setqctrl *hiwater lowater bufisz interval*
Set the audit queue write buffer size (bytes), hiwater audit record count, lowater audit record count, and wakeup interval (ticks).
- setqdelay *interval*
Set the audit queue wakeup interval (ticks). This determines the interval at which the kernel pokes the audit queue, to write audit records to the audit trail.
- setqhiwater *hiwater*
Set the number of undelivered audit records in the audit queue at which audit record generation blocks.

```

-setqlowater lowater
    Set the number of undelivered audit records in the audit queue at which blocked
    auditing processes unblock.

-setsmask asid flags
    Set the preselection mask of all processes with the specified audit session ID.

-setstat
    Reset audit statistics counters.

-setumask asid flags
    Set the preselection mask of all processes with the specified audit ID.

```

EXAMPLES **EXAMPLE 1** A sample auditconfig program

```

#
# map kernel audit event number 10 to the "fr" audit class
#
% auditconfig -setclass 10 fr

#
# turn on inclusion of exec arguments in exec audit records
#
% auditconfig -setpolicy +argv

```

EXIT STATUS 0 Successful completion.

1 An error occurred.

auditd(1M)

NAME	auditd – audit daemon
SYNOPSIS	<code>/usr/sbin/auditd</code>
DESCRIPTION	<p>The audit daemon controls the generation and location of audit trail files. If auditing is desired, auditd reads the <code>audit_control(4)</code> file to get a list of directories into which audit files can be written and the percentage limit for how much space to reserve on each filesystem before changing to the next directory.</p> <p>If auditd receives the signal <code>SIGUSR1</code>, the current audit file is closed and another is opened. If <code>SIGHUP</code> is received, the current audit trail is closed, the <code>audit_control</code> file reread, and a new trail is opened. If <code>SIGTERM</code> is received, the audit trail is closed and auditing is terminated. The program <code>audit(1M)</code> sends these signals and is recommended for this purpose.</p> <p>Each time the audit daemon opens a new audit trail file, it updates the file <code>audit_data(4)</code> to include the correct name.</p>
Auditing Conditions	<p>The audit daemon invokes the program <code>audit_warn(1M)</code> under the following conditions with the indicated options:</p> <p><code>audit_warn soft pathname</code> The file system upon which <i>pathname</i> resides has exceeded the minimum free space limit defined in <code>audit_control(4)</code>. A new audit trail has been opened on another file system.</p> <p><code>audit_warn allsoft</code> All available file systems have been filled beyond the minimum free space limit. A new audit trail has been opened anyway.</p> <p><code>audit_warn hard pathname</code> The file system upon which <i>pathname</i> resides has filled or for some reason become unavailable. A new audit trail has been opened on another file system.</p> <p><code>audit_warn allhard count</code> All available file systems have been filled or for some reason become unavailable. The audit daemon will repeat this call to <code>audit_warn</code> every twenty seconds until space becomes available. <i>count</i> is the number of times that <code>audit_warn</code> has been called since the problem arose.</p> <p><code>audit_warn ebusy</code> There is already an audit daemon running.</p> <p><code>audit_warn tmpfile</code> The file <code>/etc/security/audit/audit_tmp</code> exists, indicating a fatal error.</p> <p><code>audit_warn nostart</code> The internal system audit condition is <code>AUC_FCHDONE</code>. Auditing cannot be started without rebooting the system.</p>

audit_warn auditoff

The internal system audit condition has been changed to not be AUC_AUDITING by someone other than the audit daemon. This causes the audit daemon to exit.

audit_warn postsigterm

An error occurred during the orderly shutdown of the auditing system.

audit_warn getacdir

There is a problem getting the directory list from /etc/security/audit/audit_control.

The audit daemon will hang in a sleep loop until this file is fixed.

FILES /etc/security/audit/audit_control

/etc/security/audit/audit_data

auditreduce(1M)

NAME	auditreduce – merge and select audit records from audit trail files
SYNOPSIS	auditreduce [<i>options</i>] [<i>audit-trail-file...</i>]
DESCRIPTION	<p>auditreduce allows you to select or merge records from audit trail files. Audit files may be from one or more machines.</p> <p>The merge function merges together audit records from one or more input audit trail files into a single output file. The records in an audit trail file are assumed to be sorted in chronological order (oldest first) and this order is maintained by auditreduce in the output file.</p> <p>Unless instructed otherwise, auditreduce will merge the entire audit trail, which consists of all the audit trail files in the directory structure <i>audit_root_dir</i>/*/files (see <i>audit_control(4)</i> for details of the structure of the audit root). Unless stated with the <i>-R</i> or <i>-S</i> option, <i>audit_root_dir</i> defaults to <i>/etc/security/audit</i>. By using the file selection options it is possible to select some subset of these files, or files from another directory, or files named explicitly on the command line.</p> <p>The select function allows audit records to be selected on the basis of numerous criteria relating to the record's content (see <i>audit.log(4)</i> for details of record content). A record must meet all of the <i>record-selection-option</i> criteria to be selected.</p>
Audit Trail Filename Format	<p>Any audit trail file not named on the command line must conform to the audit trail filename format. Files produced by the audit system already have this format. Output file names produced by auditreduce are in this format. It is:</p> <p><i>start-time . end-time . suffix</i></p> <p>where <i>start-time</i> is the 14-character timestamp of when the file was opened, <i>end-time</i> is the 14-character timestamp of when the file was closed, and <i>suffix</i> is the name of the machine which generated the audit trail file, or some other meaningful suffix (e.g., <i>all</i>, if the file contains a combined group of records from many machines). The <i>end-time</i> may be the literal string <i>not_terminated</i>, to indicate that the file is still being written to by the audit system. Timestamps are of the form <i>yyyymmddhhmmss</i> (year, month, day, hour, minute, second). The timestamps are in Greenwich Mean Time (GMT).</p>
File Selection Options	<p>The file selection options indicate which files are to be processed and certain types of special treatment.</p> <p><i>-A</i></p> <p>All of the records from the input files will be selected regardless of their timestamp. This option effectively disables the <i>-a</i>, <i>-b</i>, and <i>-d</i> options. This is useful in preventing the loss of records if the <i>-D</i> option is used to delete the input files after they are processed. Note, however, that if a record is <i>not</i> selected due to another option, then <i>-A</i> will not override that.</p>

-C

Only process complete files. Files whose filename *end-time* timestamp is `not_terminated` are not processed (such a file is currently being written to by the audit system). This is useful in preventing the loss of records if `-D` is used to delete the input files after they are processed. It does not apply to files specified on the command line.

-D *suffix*

Delete input files after they deleted if the entire run is successful. If `auditreduce` detects an error while reading a file, then that file is not deleted. If `-D` is specified, `-A`, `-C` and `-O` are also implied. *suffix* is given to the `-O` option. This helps prevent the loss of audit records by ensuring that all of the records are written, only complete files are processed, and the records are written to a file before being deleted. Note that if both `-D` and `-O` are specified in the command line, the order of specification is significant. The *suffix* associated with the latter specification is in effect.

-M *machine*

Allows selection of records from files with *machine* as the filename suffix. If `-M` is not specified, all files are processed regardless of suffix. `-M` can also be used to allow selection of records from files that contain combined records from many machines and have a common suffix (such as `all`).

-N

Select objects in *new mode*. This flag is off by default, thus retaining backward compatibility. In the existing, *old mode*, specifying the `-e`, `-f`, `-g`, `-r`, or `-u` flags would select not only actions taken with those IDs, but also certain objects owned by those IDs. When running in *new mode*, only actions are selected. In order to select objects, the `-o` option must be used.

-O *suffix*

Direct output stream to a file in the current `audit_root_dir` with the indicated suffix. *suffix* may alternatively contain a full pathname, in which case the last component is taken as the suffix, ahead of which the timestamps will be placed, ahead of which the remainder of the pathname will be placed. If the `-O` option is not specified, the output is sent to the standard output. When `auditreduce` places timestamps in the filename, it uses the times of the first and last records in the merge as the *start-time* and *end-time*.

-Q

Quiet. Suppress notification about errors with input files.

-R *pathname*

Specify the pathname of an alternate audit root directory `audit_root_dir` to be *pathname*. Therefore, rather than using `/etc/security/audit/*/files` by default, `pathname/*/files` will be examined instead.

-S *server*

This option causes `auditreduce` to read audit trail files from a specific location (server directory). *server* is normally interpreted as the name of a subdirectory of

auditreduce(1M)

the audit root, therefore `auditreduce` will look in `audit_root_dir/server/files` for the audit trail files. But if `server` contains any `'/'` characters, it is the name of a specific directory not necessarily contained in the audit root. In this case, `server/files` will be consulted. This option allows archived files to be manipulated easily, without requiring that they be physically located in a directory structure like that of `/etc/security/audit`.

`-V`

Verbose. Display the name of each file as it is opened, and how many records total were written to the output stream.

Record Selection Options

The record selection options listed below are used to indicate which records are written to the output file produced by `auditreduce`.

Multiple arguments of the same type are not permitted.

`-a date-time`

Select records that occurred at or after *date-time*. The *date-time* argument is described under `Option Arguments`, below. *date-time* is in local time. The `-a` and `-b` options can be used together to form a range.

`-b date-time`

Select records that occurred before *date-time*.

`-c audit-classes`

Select records by audit class. Records with events that are mapped to the audit classes specified by *audit-classes* are selected. Audit class names are defined in `audit_class(4)`. The *audit-classes* can be a comma separated list of *audit flags* like those described in `audit_control(4)`. Using the *audit flags*, one can select records based upon success and failure criteria.

`-d date-time`

Select records that occurred on a specific day (a 24-hour period beginning at 00:00:00 of the day specified and ending at 23:59:59). The day specified is in local time. The time portion of the argument, if supplied, is ignored. Any records with timestamps during that day are selected. If any hours, minutes, or seconds are given in *time*, they are ignored. `-d` can not be used with `-a` or `-b`.

`-e effective-user`

Select records with the specified *effective-user*.

`-f effective-group`

Select records with the specified *effective-group*.

`-g real-group`

Select records with the specified *real-group*.

`-j subject-ID`

Select records with the specified *subject-ID* where *subject-ID* is a process ID.

-m *event*

Select records with the indicated *event*. The *event* is the literal string or the *event* number.

-o *object_type=objectID_value*

Select records by object type. A match occurs when the record contains the information describing the specified *object_type* and the object ID equals the value specified by *objectID_value*. The allowable object types and values are as follows:

file=pathname

Select records containing file system objects with the specified pathname, where pathname is a comma separated list of regular expressions. If a regular expression is preceded by a tilde (~), files matching the expression are excluded from the output. For example, the option *file=~usr/openwin,usr,etc* would select all files in *usr* or *etc* except those in *usr/openwin*. The order of the regular expressions is important because *auditreduce* processes them from left to right, and stops when a file is known to be either selected or excluded. Thus the option *file=usr,etc,~usr/openwin* would select all files in *usr* and all files in *etc*. Files in *usr/openwin* are not excluded because the regular expression *usr* is matched first. Care should be given in surrounding the *pathname* with quotes so as to prevent the shell from expanding any tildes.

filegroup=group

Select records containing file system objects with *group* as the owning group.

fileowner=user

Select records containing file system objects with *user* as the owning user.

msgqid=ID

Select records containing message queue objects with the specified *ID* where *ID* is a message queue ID.

msgqgroup=group

Select records containing message queue objects with *group* as the owning or creating group.

msgqowner=user

Select records containing message queue objects with *user* as the owning or creating user.

pid=ID

Select records containing process objects with the specified *ID* where *ID* is a process ID. Process are objects when they are receivers of signals.

procgroup=group

Select records containing process objects with *group* as the real or effective group.

procowner=user

Select records containing process objects with *user* as the real or effective user.

auditreduce(1M)

semid=ID

Select records containing semaphore objects with the specified *ID* where *ID* is a semaphore ID.

semgroup=group

Select records containing semaphore objects with *group* as the owning or creating group.

semowner=user

Select records containing semaphore objects with *user* as the owning or creating user.

shmid=ID

Select records containing shared memory objects with the specified *ID* where *ID* is a shared memory ID.

shmgroup=group

Select records containing shared memory objects with *group* as the owning or creating group.

shmowner=user

Select records containing shared memory objects with *user* as the owning or creating user.

sock=port_number | machine

Select records containing socket objects with the specified *port_number* or the specified *machine* where *machine* is a machine name as defined in `hosts(4)`.

-r real-user

Select records with the specified *real-user*.

-u audit-user

Select records with the specified *audit-user*. When one or more *filename* arguments appear on the command line, only the named files are processed. Files specified in this way need not conform to the audit trail filename format. However, *-M*, *-S*, and *-R* may not be used when processing named files. If the *filename* is *"-"* then the input is taken from the standard input.

Option Arguments

audit-trail-file

An audit trail file as defined in `audit.log(4)`. An audit trail file not named on the command line must conform to the audit trail file name format. Audit trail files produced as output of `auditreduce` are in this format as well. The format is:

start-time . end-time . suffix

start-time is the 14 character time stamp denoting when the file was opened.

end-time is the 14 character time stamp denoting when the file was closed. *end-time* may also be the literal string `not_terminated`, indicating the file is still be written to by the audit daemon or the file was not closed properly (a system crash or abrupt halt occurred). *suffix* is the name of the machine that generated the audit trail

file (or some other meaningful suffix; e.g. `all` would be a good suffix if the audit trail file contains a combined group of records from many machines).

date-time

The *date-time* argument to `-a`, `-b`, and `-d` can be of two forms: An absolute *date-time* takes the form:

```
yyyymmdd [ hh [ mm [ ss ] ] ]
```

where *yyyy* specifies a year (with 1970 as the earliest value), *mm* is the month (01-12), *dd* is the day (01-31), *hh* is the hour (00-23), *mm* is the minute (00-59), and *ss* is the second (00-59). The default is 00 for *hh*, *mm* and *ss*.

An offset can be specified as: `+n d|h|m|s` where *n* is a number of units, and the tags *d*, *h*, *m*, and *s* stand for days, hours, minutes and seconds, respectively. An offset is relative to the starting time. Thus, this form can only be used with the `-b` option.

event

The literal string or ordinal event number as found in `audit_event(4)`. If *event* is not found in the `audit_event` file it is considered invalid.

group

The literal string or ordinal group ID number as found in `group(4)`. If *group* is not found in the `group` file it is considered invalid. *group* may be negative.

pathname

A regular expression describing a pathname.

user

The literal username or ordinal user ID number as found in `passwd(4)`. If the username is not found in the `passwd` file it is considered invalid. *user* may be negative.

EXAMPLES **EXAMPLE 1** The `auditreduce` command.

`praudit(1M)` is available to display audit records in a human-readable form.

This will display the entire audit trail in a human-readable form:

```
% auditreduce | praudit
```

If all the audit trail files are being combined into one large file, then deleting the original files could be desirable to prevent the records from appearing twice:

```
% auditreduce -v -d /etc/security/audit/combined/all
```

This will print what user `milner` did on April 13, 1988. The output will be displayed in a human-readable form to the standard output:

```
% auditreduce -d 19880413 -u milner | praudit
```

auditreduce(1M)

EXAMPLE 1 The `auditreduce` command. (Continued)

The above example may produce a large volume of data if `milner` has been busy. Perhaps looking at only login and logout times would be simpler. The `-c` option will select records from a specified class:

```
% auditreduce -d 19880413 -u milner -c lo | praudit
```

To see `milner`'s login/logout activity for April 13, 14, and 15 the following is used. The results are saved to a file in the current working directory. Note that the name of the output file will have `milnerlo` as the *suffix*, with the appropriate timestamp prefixes. Note that the long form of the name is used for the `-c` option:

```
% auditreduce -a 19880413 -b +3d -u milner -c login_logout -o milnerlo
```

To follow `milner`'s movement about the file system on April 13, 14, and 15 the `chdir` record types could be viewed. Note that in order to get the same time range as the above example we needed to specify the `-b` time as the day after our range. This is because 19880416 defaults to midnight of that day, and records before that fall on 0415, the end-day of the range.

```
% auditreduce -a 19880413 -b 19880416 -u milner -m AUE_CHDIR | praudit
```

In this example the audit records are being collected in summary form (the login/logout records only). The records are being written to a summary file in a different directory than the normal audit root to prevent the selected records from existing twice in the audit root.

```
% auditreduce -d 19880330 -c lo -o /etc/security/audit_summary/logins
```

If activity for user ID 9944 has been observed, but that user is not known to the system administrator, then the following example will search the entire audit trail for any records generated by that user. `auditreduce` will query the system as to the current validity of ID 9944, and print a warning message if it is not currently active:

```
% auditreduce -o /etc/security/audit_suspect/user9944 -u 9944
```

FILES `/etc/security/audit/server/files/*`
location of audit trails, when stored

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `bsmconv(1M)`, `praudit(1M)`, `audit.log(4)`, `audit_class(4)`, `audit_control(4)`, `group(4)`, `hosts(4)`, `passwd(4)`, `attributes(5)`

DIAGNOSTICS	<p>auditreduce will print out error messages if there are command line errors and then exit. If there are fatal errors during the run auditreduce will print an explanatory message and exit. In this case the output file may be in an inconsistent state (no trailer or partially written record) and auditreduce will print a warning message before exiting. Successful invocation returns 0 and unsuccessful invocation returns 1.</p> <p>Since auditreduce may be processing a large number of input files, it is possible that the machine-wide limit on open files will be exceeded. If this happens, auditreduce will print a message to that effect, give information on how many file there are, and exit.</p> <p>If auditreduce prints a record's timestamp in a diagnostic message, that time is in local time. However, when filenames are displayed, their timestamps are in GMT.</p>
BUGS	<p>Conjunction, disjunction, negation, and grouping of record selection options should be allowed.</p>
NOTES	<p>The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.</p>

audit_startup(1M)

NAME	audit_startup – audit subsystem initialization script
SYNOPSIS	<code>/etc/security/audit_startup</code>
DESCRIPTION	The <code>audit_startup</code> script is used to initialize the audit subsystem before the audit daemon is started. This script is configurable by the system administrator, and currently consists of a series of <code>auditconfig(1M)</code> commands to set the system default policy, and download the initial event to class mapping.
SEE ALSO	<code>auditconfig(1M)</code> , <code>auditd(1M)</code> , <code>bsmconv(1M)</code> , <code>attributes(5)</code>
NOTES	The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See <code>bsmconv(1M)</code> for more information.

NAME	auditstat – display kernel audit statistics
SYNOPSIS	auditstat [-c <i>count</i>] [-h <i>numlines</i>] [-i <i>interval</i>] [-n] [-v]
DESCRIPTION	<p>auditstat displays kernel audit statistics. The fields displayed are as follows:</p> <p>aud The total number of audit records processed by the audit(2) system call.</p> <p>ctl This field is obsolete.</p> <p>drop The total number of audit records that have been dropped. Records are dropped according to the kernel audit policy. See auditon(2), AUDIT_CNT policy for details.</p> <p>enq The total number of audit records put on the kernel audit queue.</p> <p>gen The total number of audit records that have been constructed (not the number written).</p> <p>kern The total number of audit records produced by user processes (as a result of system calls).</p> <p>mem The total number of Kbytes of memory currently in use by the kernel audit module.</p> <p>nona The total number of non-attributable audit records that have been constructed. These are audit records that are not attributable to any particular user.</p> <p>rblk The total number of times that auditsvc(2) has blocked waiting to process audit data.</p> <p>tot The total number of Kbytes of audit data written to the audit trail.</p> <p>wblk The total number of times that user processes blocked on the audit queue at the high water mark.</p> <p>wrtn The total number of audit records written. The difference between enq and wrtn is the number of outstanding audit records on the audit queue that have not been written.</p>
OPTIONS	<p>-c <i>count</i> Display the statistics a total of <i>count</i> times. If <i>count</i> is equal to zero, statistics are displayed indefinitely. A time interval must be specified.</p> <p>-h <i>numlines</i> Display a header for every <i>numlines</i> of statistics printed. The default is to display the header every 20 lines. If <i>numlines</i> is equal to zero, the header is never displayed.</p> <p>-i <i>interval</i> Display the statistics every <i>interval</i> where <i>interval</i> is the number of seconds to sleep between each collection.</p> <p>-n Display the number of kernel audit events currently configured.</p> <p>-v Display the version number of the kernel audit module software.</p>

auditstat(1M)

EXIT STATUS | auditstat returns 0 upon success and 1 upon failure.

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

NAME	audit_warn – audit daemon warning script	
SYNOPSIS	/etc/security/audit_warn [option [arguments]]	
DESCRIPTION	<p>The audit_warn script processes warning or error messages from the audit daemon. When a problem is encountered, the audit daemon, auditd(1M) calls audit_warn with the appropriate arguments. The <i>option</i> argument specifies the error type.</p> <p>The system administrator can specify a list of mail recipients to be notified when an audit_warn situation arises by defining a mail alias called audit_warn in aliases(4). The users that make up the audit_warn alias are typically the audit and root users.</p>	
OPTIONS	allhard <i>count</i>	Indicates that the hard limit for all filesystems has been exceeded <i>count</i> times. The default action for this option is to send mail to the audit_warn alias only if the <i>count</i> is 1, and to write a message to the machine console every time. It is recommended that mail <i>not</i> be sent every time as this could result in a the saturation of the file system that contains the mail spool directory.
	allsoft	Indicates that the soft limit for all filesystems has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.
	auditoff	Indicates that someone other than the audit daemon changed the system audit state to something other than AUC_AUDITING. The audit daemon will have exited in this case. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.
	ebusy	Indicates that the audit daemon is already running. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.
	getacdir <i>count</i>	Indicates that there is a problem getting the directory list from audit_control(4). The audit daemon will hang in a sleep loop until the file is fixed. The default action for this option is to send mail to the audit_warn alias only if <i>count</i> is 1, and to write a message to the machine console every time. It is recommended that mail <i>not</i> be sent every time as this could result in a the saturation of the file system that contains the mail spool directory.
	hard <i>filename</i>	Indicates that the hard limit for the file has been exceeded. The default action for this option is to send

audit_warn(1M)

	mail to the <code>audit_warn</code> alias and to write a message to the machine console.
<code>nostart</code>	Indicates that auditing could not be started. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console. Some administrators may prefer to modify <code>audit_warn</code> to reboot the system when this error occurs.
<code>postsigterm</code>	Indicates that an error occurred during the orderly shutdown of the audit daemon. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console.
<code>soft filename</code>	Indicates that the soft limit for <i>filename</i> has been exceeded. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console.
<code>tmpfile</code>	Indicates that the temporary audit file already exists indicating a fatal error. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr

SEE ALSO `audit(1M)`, `auditd(1M)`, `bsmconv(1M)`, `aliases(4)`, `audit.log(4)`, `audit_control(4)`, `attributes(5)`

NAME	automount – install automatic mount points
SYNOPSIS	<code>/usr/sbin/automount</code> [-t <i>duration</i>] [-v]
DESCRIPTION	<p>The automount utility installs <code>autofs</code> mount points and associates an automount map with each mount point. The <code>autofs</code> file system monitors attempts to access directories within it and notifies the <code>automountd(1M)</code> daemon. The daemon uses the map to locate a file system, which it then mounts at the point of reference within the <code>autofs</code> file system. A map can be assigned to an <code>autofs</code> mount using an entry in the <code>/etc/auto_master</code> map or a direct map.</p> <p>If the file system is not accessed within an appropriate interval (10 minutes by default), the <code>automountd</code> daemon unmounts the file system.</p> <p>The file <code>/etc/auto_master</code> determines the locations of all <code>autofs</code> mount points. By default, this file contains four entries:</p> <pre># Master map for automounter # +auto_master /net -hosts -nosuid /home auto_home /xfn -xfn</pre> <p>The <code>+auto_master</code> entry is a reference to an external NIS or NIS+ master map. If one exists, then its entries are read as if they occurred in place of the <code>+auto_master</code> entry. The remaining entries in the master file specify a directory on which an <code>autofs</code> mount will be made followed by the automounter map to be associated with it. Optional mount options may be supplied as an optional third field in the each entry. These options are used for any entries in the map that do not specify mount options explicitly. The automount command is usually run without arguments. It compares the entries <code>/etc/auto_master</code> with the current list of <code>autofs</code> mounts in <code>/etc/mnttab</code> and adds, removes or updates <code>autofs</code> mounts to bring the <code>/etc/mnttab</code> up to date with the <code>/etc/auto_master</code>. At boot time it installs all <code>autofs</code> mounts from the master map. Subsequently, it may be run to install <code>autofs</code> mounts for new entries in the master map or the direct map, or to perform unmounts for entries that have been removed from these maps.</p>
OPTIONS	<p>The following options are supported:</p> <p>-t <i>duration</i> Specifies a <i>duration</i>, in seconds, that a file system is to remain mounted when not in use. The default is 10 minutes.</p> <p>-v Verbose mode. Notifies of <code>autofs</code> mounts, unmounts, or other non-essential information.</p>
Map Entry Format	<p>A simple map entry (mapping) takes the form:</p> <pre>key [-mount-options] location . . .</pre>

automount(1M)

where *key* is the full pathname of the directory to mount when used in a direct map, or the simple name of a subdirectory in an indirect map. *mount-options* is a comma-separated list of mount options, and *location* specifies a file system from which the directory may be mounted. In the case of a simple NFS mount, the options that can be used are as specified in `mount_nfs(1M)`, and *location* takes the form:

```
host : pathname
```

host is the name of the host from which to mount the file system, and *pathname* is the absolute pathname of the directory to mount.

Options to other file systems are documented on the other `mount_*` reference manual pages, for example, `mount_cacheFs(1M)`.

Replicated File Systems

Multiple *location* fields can be specified for replicated NFS file systems, in which case `automount` and the kernel will each try to use that information to increase availability. If the read-only flag is set in the map entry, `automount` mounts a list of locations that the kernel may use, sorted by several criteria. When a server does not respond, the kernel will switch to an alternate server. The sort ordering of `automount` is used to determine how the next server is chosen. If the read-only flag is not set, `automount` will mount the best single location, chosen by the same sort ordering, and new servers will only be chosen when an unmount has been possible, and a remount is done. Servers on the same local subnet are given the strongest preference, and servers on the local net are given the second strongest preference. Among servers equally far away, response times will determine the order if no weighting factors (see below) are used.

If the list includes server locations using both the NFS Version 2 Protocol and the NFS Version 3 Protocol, `automount` will choose only a subset of the server locations on the list, so that all entries will be the same protocol. It will choose servers with the NFS Version 3 Protocol so long as an NFS Version 2 Protocol server on a local subnet will not be ignored. See the *System Administration Guide: IP Services* for additional details.

If each *location* in the list shares the same *pathname* then a single *location* may be used with a comma-separated list of hostnames:

```
hostname,hostname . . . : pathname
```

Requests for a server may be weighted, with the weighting factor appended to the server name as an integer in parentheses. Servers without a weighting are assumed to have a value of zero (most likely to be selected). Progressively higher values decrease the chance of being selected. In the example,

```
man -ro alpha,bravo,charlie(1),delta(4) : /usr/man
```

hosts `alpha` and `bravo` have the highest priority; host `delta` has the lowest.

Server proximity takes priority in the selection process. In the example above, if the server `delta` is on the same network segment as the client, but the others are on different network segments, then `delta` will be selected; the weighting value is ignored. The weighting has effect only when selecting between servers with the same network proximity.

In cases where each server has a different export point, the weighting can still be applied. For example:

```
man -ro alpha:/usr/man bravo,charlie(1):/usr/share/man
      delta(3):/export/man
```

A mapping can be continued across input lines by escaping the NEWLINE with a backslash (\) Comments begin with a number sign (#) and end at the subsequent NEWLINE.

Map Key Substitution

The ampersand (&) character is expanded to the value of the key field for the entry in which it occurs. In this case:

```
jane sparcserver : /home/&
```

the & expands to jane.

Wildcard Key

The asterisk (*) character, when supplied as the key field, is recognized as the catch-all entry. Such an entry will match any key not previously matched. For instance, if the following entry appeared in the indirect map for `/config`:

```
*          & : /export/config/&
```

this would allow automatic mounts in `/config` of any remote file system whose location could be specified as:

```
hostname : /export/config/hostname
```

Variable Substitution

Client specific variables can be used within an automount map. For instance, if `$HOST` appeared within a map, `automount` would expand it to its current value for the client's host name. Supported variables are:

ARCH	The application architecture is derived from the output of <code>uname -m</code>	The architecture name. For example, "sun4" on a sun4u machine.
CPU	The output of <code>uname -p</code>	The processor type. For example, "sparc"
HOST	The output of <code>uname -n</code>	The host name. For example, "biggles"

automount(1M)

OSNAME	The output of <code>uname -s</code>	The OS name. For example, "SunOS"
OSREL	The output of <code>uname -r</code>	The OS release name. For example "5.3"
OSVERS	The output of <code>uname -v</code>	The OS version. For example, "beta1.0"
NATISA	The output of <code>isainfo -n</code>	The native instruction set architecture for the system. For example, "sparcv9"

If a reference needs to be protected from affixed characters, you can surround the variable name with curly braces (`{ }`).

Multiple Mounts

A multiple mount entry takes the form:

```
key [-mount-options] [ [mountpoint] [-mount-options] location . . . ] . . .
```

The initial `/[mountpoint]` is optional for the first mount and mandatory for all subsequent mounts. The optional `mountpoint` is taken as a pathname relative to the directory named by `key`. If `mountpoint` is omitted in the first occurrence, a `mountpoint` of `/` (root) is implied.

Given an entry in the indirect map for `/src`

```
beta      -ro\  
/         svr1,svr2:/export/src/beta  \  
/1.0     svr1,svr2:/export/src/beta/1.0  \  
/1.0/man svr1,svr2:/export/src/beta/1.0/man
```

All offsets must exist on the server under `beta`. `automount` will automatically mount `/src/beta`, `/src/beta/1.0`, and `/src/beta/1.0/man`, as needed, from either `svr1` or `svr2`, whichever host is nearest and responds first.

Other File System Types

The automounter assumes NFS mounts as a default file system type. Other file system types can be described using the `fstype` mount option. Other mount options specific to this file system type can be combined with the `fstype` option. The location field must contain information specific to the file system type. If the location field begins with a slash, a colon character must be prepended, for instance, to mount a CD file system:

```
cdrom -fstype=hsfs,ro : /dev/sr0
```

or to perform an `autofs` mount:

```
src -fstype=autofs auto_src
```

Note: Use this procedure only if you are not using Volume Manager.

Mounts using CacheFS are most useful when applied to an entire map as map defaults. The following entry in the master map describes cached home directory mounts. It assumes the default location of the cache directory, `/cache`.

```
/home auto_home -fstype=cachefs,backfstype=nfs
```

See the NOTES section for information on option inheritance.

- Indirect Maps** An indirect map allows you to specify mappings for the subdirectories you wish to mount under the `directory` indicated on the command line. In an indirect map, each key consists of a simple name that refers to one or more file systems that are to be mounted as needed.
- Direct Maps** Entries in a direct map are associated directly with `autofs` mount points. Each key is the full pathname of an `autofs` mount point. The direct map as a whole is not associated with any single directory.
- Included Maps** The contents of another map can be included within a map with an entry of the form
- ```
+mapname
```
- If *mapname* begins with a slash, it is assumed to be the pathname of a local file. Otherwise, the location of the map is determined by the policy of the name service switch according to the entry for the automounter in `/etc/nsswitch.conf`, such as
- ```
automount: files nis
```
- If the name service is `files`, then the name is assumed to be that of a local file in `/etc`. If the key being searched for is not found in the included map, the search continues with the next entry.
- Special Maps** There are three special maps available: `-hosts`, `-xfn`, and `-null`. The `-hosts` map is used with the `/net` directory and assumes that the map key is the hostname of an NFS server. The `automountd` daemon dynamically constructs a map entry from the server's list of exported file systems. References to a directory under `/net/hermes` will refer to the corresponding directory relative to `hermes` root.
- The `-xfn` map is used to mount the initial context of the Federated Naming Service (FNS) namespace under the `/xfn` directory. For more information on FNS, see `fns(5)`, `fns_initial_context(5)`, `fns_policies(5)`, and the Federated Naming Service Guide.
- The `-null` map cancels a previous map for the directory indicated. This is most useful in the `/etc/auto_master` for cancelling entries that would otherwise be inherited

automount(1M)

from the `+auto_master` include entry. To be effective, the `-null` entries must be inserted before the included map entry.

Executable Maps

Local maps that have the execute bit set in their file permissions will be executed by the automounter and provided with a key to be looked up as an argument. The executable map is expected to return the content of an automounter map entry on its stdout or no output if the entry cannot be determined. A direct map cannot be made executable.

Configuration and the `auto_master` Map

When initiated without arguments, `automount` consults the master map for a list of `autofs` mount points and their maps. It mounts any `autofs` mounts that are not already mounted, and unmounts `autofs` mounts that have been removed from the master map or direct map.

The master map is assumed to be called `auto_master` and its location is determined by the name service switch policy. Normally the master map is located initially as a local file `/etc/auto_master`.

Browsing

The Solaris 2.6 release supports browsability of indirect maps. This allows all of the potential mount points to be visible, whether or not they are mounted. The `-nobrowse` option can be added to any indirect `autofs` map to disable browsing. For example:

```
/net      -hosts      -nosuid,nobrowse
/home     auto_home
```

In this case, any *hostnames* would only be visible in `/net` after they are mounted, but all potential mount points would be visible under `/home`. The `-browse` option enables browsability of `autofs` file systems. This is the default for all indirect maps.

EXIT STATUS

The following exit values are returned:

```
0          Successful completion.
1          An error occurred.
```

FILES

```
/etc/auto_master      master automount map.
/etc/auto_home        map to support automounted home directories.
/etc/nsswitch.conf    the name service switch configuration file.
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

automount(1M)

SEE ALSO isainfo(1), ls(1), uname(1), automountd(1M), mount(1M), mount_cachefs(1M), mount_nfs(1M), attributes(5), fns(5), fns_initial_context(5), fns_policies(5), nfssec(5)

System Administration Guide: IP Services

NOTES autofs mount points must not be hierarchically related. automount does not allow an autofs mount point to be created within another autofs mount.

Since each direct map entry results in a new autofs mount such maps should be kept short.

Entries in both direct and indirect maps can be modified at any time. The new information is used when automountd next uses the map entry to do a mount.

New entries added to a master map or direct map will not be useful until the automount command is run to install them as new autofs mount points. New entries added to an indirect map may be used immediately.

As of the Solaris 2.6 release, a listing (see ls(1)) of the autofs directory associated with an indirect map shows all potential mountable entries. The attributes associated with the potential mountable entries are temporary. The real file system attributes will only be shown once the file system has been mounted.

Default mount options can be assigned to an entire map when specified as an optional third field in the master map. These options apply only to map entries that have no mount options. Note that map entities with options override the default options, as at this time, the options do not concatenate. The concatenation feature is planned for a future release.

When operating on a map that invokes an NFS mount, the default number of retries for the automounter is 0, that is, a single mount attempt, with no retries. Note that this is significantly different from the default (10000) for the mount_nfs(1M) utility.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same.

automountd(1M)

NAME automountd – autofs mount/unmount daemon

SYNOPSIS **automountd** [-Tvn] [-D *name=value*]

DESCRIPTION automountd is an RPC server that answers file system mount and unmount requests from the autofs file system. It uses local files or name service maps to locate file systems to be mounted. These maps are described with the automount(1M) command.

The automountd daemon is automatically invoked in run level 2.

OPTIONS

- T Trace. Expand each RPC call and display it on the standard output.
- v Verbose. Log status messages to the console.
- n Turn off browsing for all autofs mount points. This option overrides the -browse autofs map option on the local host.
- D *name=value* Assign *value* to the indicated automount map substitution variable. These assignments cannot be used to substitute variables in the master map auto_master.

USAGE See largefile(5) for the description of the behavior of automountd when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

FILES /etc/auto_master master map for automounter

NAME	autopush – configures lists of automatically pushed STREAMS modules
SYNOPSIS	<pre>autopush -f filename autopush -g -M major -m minor autopush -r -M major -m minor</pre>
DESCRIPTION	The autopush command configures the list of modules to be automatically pushed onto the stream when a device is opened. It can also be used to remove a previous setting or get information on a setting.
OPTIONS	<p>The following options are supported:</p> <p>-f filename Sets up the autopush configuration for each driver according to the information stored in <i>filename</i>. An autopush file consists of lines of four or more fields, separated by spaces as shown below:</p> <pre>major minor last-minor module1 module2 . . . module8</pre> <p>The first field is a string that specifies the <i>major</i> device name, as listed in the <code>/kernel/drv</code> directory. The next two fields are integers that specify the <i>minor</i> device number and <i>last-minor</i> device number. The fields following represent the names of modules. If <i>minor</i> is <code>-1</code>, then all minor devices of a major driver specified by <i>major</i> are configured, and the value for <i>last-minor</i> is ignored. If <i>last-minor</i> is <code>0</code>, then only a single minor device is configured. To configure a range of minor devices for a particular major, <i>minor</i> must be less than <i>last-minor</i>.</p> <p>The remaining fields list the names of modules to be automatically pushed onto the stream when opened, along with the position of an optional anchor. The maximum number of modules that can be pushed is eight. The modules are pushed in the order they are specified. The optional special character sequence [<i>anchor</i>] indicates that a STREAMS anchor should be placed on the stream at the module previously specified in the list; it is an error to specify more than one anchor or to have an anchor first in the list.</p> <p>A nonzero exit status indicates that one or more of the lines in the specified file failed to complete successfully.</p> <p>-g Gets the current configuration setting of a particular <i>major</i> and <i>minor</i> device number specified with the <code>-M</code> and <code>-m</code> options respectively and displays the autopush modules associated with it. It will also return the starting minor device number if the request corresponds to a setting of a range (as described with the <code>-f</code> option).</p> <p>-m minor Specifies the minor device number.</p>

autopush(1M)

-M *major* Specifies the major device number.

-r Removes the previous configuration setting of the particular *major* and *minor* device number specified with the **-M** and **-m** options respectively. If the values of *major* and *minor* correspond to a previously established setting of a range of minor devices, where *minor* matches the first minor device number in the range, the configuration would be removed for the entire range.

EXIT STATUS The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

EXAMPLES **EXAMPLE 1** Using the autopush command.

The following example gets the current configuration settings for the *major* and *minor* device numbers as indicated and displays the autopush modules associated with them for the character-special device `/dev/term/a`:

```
example# autopush -g -M 29 -m 0
Major      Minor      Lastminor  Modules
   29         0           1      ldterm ttcompat
```

FILES `/etc/iu.ap`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

STREAMS Programming Guide

NAME	bdconfig – configures the bd (buttons and dials) stream				
SYNOPSIS	bdconfig [<i>startup</i>] [<i>off</i>] [<i>on</i>] [<i>term</i>] [<i>status</i>] [<i>verbose</i>]				
DESCRIPTION	The <code>bdconfig</code> utility is responsible for configuring the autopush facility and defining to the system what serial device to use for the <code>bd</code> stream.				
OPTIONS	<p>If no options are given, then an interactive mode is assumed. In this mode the current status is presented along with this usage line, and a series of interactive questions asked to determine the user's desires.</p> <p>Root privilege is required to change the configuration. The <code>status</code> option does not require root privilege. <code>bdconfig</code> can be installed as a <code>setuid</code> root program.</p> <p>The non-interactive options below can be given in any order.</p> <p><i>term</i> Specify to the system the serial device for <code>bd</code> use. This option implies the <code>on</code> option unless the <code>off</code> option is present.</p> <p><i>iff</i> Reconfigure the configured <code>term</code> for <code>tty</code> use.</p> <p><i>on</i> Reconfigure the configured <code>term</code> for <code>bd</code> use. If <i>term</i> has not been previously specified, interactive questions are asked to determine the user's desires.</p> <p><i>startup</i> Configure as was last configured before the system went down. This option is used by the <code>startup</code> script, and precludes the use of the <code>on</code>, <code>off</code>, and <i>term</i> options. This option implies non-interactive mode.</p> <p><i>status</i> Emit the current configuration in terms of the words used as options: <code>off</code>, <code>on</code>, <code>/dev/term/a</code>, <code>/dev/term/b</code>, and so forth. This option implies non interactive mode.</p> <p><i>verbose</i> <code>bdconfig</code> describes what it finds and what it is doing.</p>				
EXIT STATUS	The <code>bdconfig</code> utility returns 0 on success, 1 on general error, and 2 on argument error.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWdialh</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWdialh
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWdialh				
SEE ALSO	<code>autopush(1M)</code> , <code>attributes(5)</code> , <code>x_buttontest(6)</code> , <code>x_dialtest(6)</code> , <code>bd(7M)</code> , <code>sad(7D)</code> , <code>streamio(7I)</code>				
NOTES	All <code>bdconfig</code> does is configure the AUTOPUSH facility. <code>bdconfig</code> does not actually manipulate the serial port or stream in any way. Only the first open of a dismantled stream will see the effects of a previously run <code>bdconfig</code> .				

bdconfig(1M)

The `bdconfig` utility is silent except for error messages unless:

- a) invoked with no args: status / usage line emitted
- b) interactive modes are invoked as described above
- c) the verbose option is used

BUGS The interface does not support more than one dialbox and one buttonbox, both of which must be on the same serial device.

There should be a library routine to read, parse, and validate records in the `iu.ap` file, so that `bdconfig` could return to the appropriate record in `iu.ap` as the default configuration.

NAME	boot – start the system kernel or a standalone program
SPARC	<p>boot [<i>OBP names</i>] [<i>file</i>] [-aϵV] [-D <i>default-file</i>] [<i>boot-flags</i>] [—] [<i>client-program-args</i>]</p> <p>b [<i>device</i> [(<i>c</i>, <i>u</i>, <i>p</i>)]] [-aϵV] [-D <i>default-file</i>] [<i>boot-flags</i>] [—] [<i>client-program-args</i>]</p>
IA	<p>b [<i>file</i>] [-ϵ] [<i>boot-args</i>]</p> <p>i</p>
DESCRIPTION	<p>Bootstrapping is the process of loading and executing a standalone program. For the purpose of this discussion, bootstrapping means the process of loading and executing the bootable operating system. Typically, the standalone program is the operating system kernel (see <code>kernel(1M)</code>), but any standalone program can be booted instead. On a SPARC-based system, the diagnostic monitor for a machine is a good example of a standalone program other than the operating system that can be booted.</p> <p>If the standalone is identified as a dynamically-linked executable, <code>boot</code> will load the interpreter (linker/loader) as indicated by the executable format and then transfer control to the interpreter. If the standalone is statically-linked, it will jump directly to the standalone.</p> <p>Once the kernel is loaded, it starts the UNIX system, mounts the necessary filesystems (see <code>vfstab(4)</code>), and runs <code>/sbin/init</code> to bring the system to the "initdefault" state specified in <code>/etc/inittab</code>. See <code>inittab(4)</code>.</p>
SPARC Bootstrap Procedure	<p>On SPARC based systems, the bootstrap procedure on most machines consists of the following basic phases.</p> <p>After the machine is turned on, the system firmware (in PROM) executes power-on self-test (POST). The form and scope of these tests depends on the version of the firmware in your system.</p> <p>After the tests have been completed successfully, the firmware attempts to autoboot if the appropriate flag has been set in the non-volatile storage area used by the firmware. The name of the file to load, and the device to load it from can also be manipulated.</p> <p>These flags and names can be set using the <code>eeeprom(1M)</code> command from the shell, or by using PROM commands from the <code>ok</code> prompt after the system has been halted.</p> <p>The second level program is either <code>ufsboot</code> (when booting from a disk), or <code>inetboot</code> (when booting across the network).</p> <p>Network Booting</p> <p>Network booting can follow either of two paths, RARP/<code>bootparams</code> or DHCP (Dynamic Host Configuration Protocol), depending on the functions available in and configuration of the PROM. Machines of the <code>sun4u</code> kernel architecture have DHCP-capable PROMs and boot from the network using RARP/<code>bootparams</code> by</p>

boot(1M)

default. Whichever network boot path is specified, RARP or DHCP, is followed all the way through to multi-user mode; there is no mixture of the RARP and DHCP activities.

The boot command syntax for specifying the two methods of network booting are:

```
boot net:rarp
boot net:dhcp
```

The command:

```
boot net
```

without a `rarp` or `dhcp` specifier, invokes the default method for network booting over the network interface for which `net` is an alias.

The sequence of events for network booting using RARP/bootparams is described in the following paragraphs. The sequence for DHCP follows the RARP/bootparams description.

When booting over the network using RARP/bootparams, the PROM makes a reverse ARP request and when it receives a reply, the PROM broadcasts a TFTP request to fetch `inetboot` over the network from any server that responds and executes it. `inetboot` also makes another reverse ARP request, then uses the bootparams protocol (see `bootparams(4)`) to locate its root filesystem. It then fetches the kernel across the network using the NFS protocol and then executes it.

When booting over the network using DHCP, the PROM broadcasts the hardware address and kernel architecture and requests an IP address, boot parameters, and network configuration information. After a DHCP server responds and is selected (from among potentially multiple servers), that server sends to the client an IP address and all other information needed to boot the client. After receipt of this information, the client PROM downloads `inetboot`, loads that file into memory, and executes it. `inetboot` invokes the kernel, which loads the files it needs and releases `inetboot`. Startup scripts then initiate the DHCP agent (see `dhcpage(1M)`), which implements the further activities of the DHCP.

Booting from Disk

When booting from disk (or disk-like device), the bootstrapping process consists of two conceptually distinct phases, primary boot and secondary boot. In the primary boot phase, the PROM loads the primary boot block from blocks 1 to 15 of the disk partition selected as the boot device.

If the pathname to the standalone is relative (does not begin with a slash), the second level boot will look for the standalone in a platform-dependent search path. This path is guaranteed to contain `/platform/platform-name`. Many SPARC platforms next search the platform-specific path entry `/platform/hardware-class-name`. See

OpenBoot PROM
boot Command
Behavior

filesystem(5). If the pathname is absolute, `boot` will use the specified path. The `boot` program then loads the standalone at the appropriate address, and then transfers control.

If the filename is not given on the command line or otherwise specified, for example, by the `boot-file` NVRAM variable, `boot` chooses an appropriate default file to load based on what software is installed on the system, the capabilities of the hardware and firmware, and on a user configurable policy file (see FILES, below).

The OpenBoot `boot` command takes arguments of the following form:

```
ok boot [device-specifier] [arguments]
```

The default `boot` command has no arguments:

```
ok boot
```

If no *device-specifier* is given on the `boot` command line, OpenBoot typically uses the *boot-device* or *diag-device* `nvr`am variable. If no optional *arguments* are given on the command line, OpenBoot typically uses the *boot-file* or *diag-file* `nvr`am variable as default `boot` arguments. (If the system is in diagnostics mode, *diag-device* and *diag-file* are used instead of *boot-device* and *boot-file*).

arguments may include more than one string. All *argument* strings are passed to the secondary booter; they are not interpreted by OpenBoot.

If any *arguments* are specified on the `boot` command line, then neither the *boot-file* nor the *diag-file* `nvr`am variable is used. The contents of the `nvr`am variables are not merged with command line arguments. For example, the command

```
ok boot -s
```

ignores the settings in both *boot-file* and *diag-file*; it interprets the string "-s" as *arguments*. `boot` will not use the contents of *boot-file* or *diag-file*.

The commands

```
ok boot netand
```

`ok boot cdrom` have no arguments; they will use the settings in *boot-file* or *diag-file*, if they are set, as default filename and arguments and pass them to `boot`. Accordingly, if *boot-file* is set to the 64-bit kernel filename and you attempt to boot the installation CD with `boot cdrom`, `boot` will fail if the installation CD contains only a 32-bit kernel.

Since the contents of *boot-file* or *diag-file* may be ignored depending on the form of the `boot` command used, reliance upon the *boot-file* should be discouraged for most production systems. To change the OS policy, change the policy file. A significant exception is when a production system has both 32-bit and 64-bit packages installed, but the production system requires use of the 32-bit OS.

In most cases, it is best to allow the `boot` command to choose an appropriate default based upon the system type, system hardware and firmware, and upon what is

boot(1M)

installed on the root filesystem. It is accepted practice to augment the `boot` command's policy by modifying the policy file; however, changing *boot-file* or *diag-file* may generate unexpected results in certain circumstances.

This behavior is found on most OpenBoot 2.x and 3.x based systems. Note that differences may occur on some platforms.

IA Bootstrap Procedure

On IA based systems, the bootstrapping process consists of two conceptually distinct phases, primary boot and secondary boot. The primary boot is implemented in the BIOS ROM on the system board, and BIOS extensions in ROMs on peripheral boards. It is distinguished by its ability to control the installed peripheral devices and to provide I/O services through software interrupts. It begins the booting process by loading the first physical sector from a floppy disk, hard disk, or CD-ROM, or, if supported by the system or network adapter BIOS, by reading a bootstrap program from a network boot server. The primary boot is implemented in IA real-mode code.

The secondary boot is loaded by the primary boot. It is implemented in 32-bit, paged, protected mode code. It also loads and uses peripheral-specific BIOS extensions written in IA real-mode code. The secondary boot is called `boot.bin` and is capable of reading and booting from a UFS file system on a hard disk or a CD or by way of a LAN using the NFS protocol.

The secondary boot is responsible for running the Configuration Assistant program which determines the installed devices in the system (possibly with help from the user). The secondary boot then reads the script in `/etc/bootrc`, which controls the booting process. This file contains `boot interpreter` commands, which are defined below, and can be modified to change defaults or to adapt to a specific machine.

The standard `/etc/bootrc` script prompts the user to enter a `b` character to boot with specified options, an `i` character to invoke the interpreter interactively, or any other character to boot the default kernel. Once the kernel is loaded, it starts the operating system, loads the necessary modules, mounts the necessary filesystems (see `vfstab(4)`), and runs `/sbin/init` to bring the system to the "initdefault" state specified in `/etc/inittab`. See `inittab(4)`.

SPARC

<i>OBP names</i>	Specify the open boot prom designations. For example, on Desktop SPARC based systems, the designation <code>/sbus/esp@0,800000/sd@3,0:a</code> indicates a SCSI disk (<code>sd</code>) at target 3, lun0 on the SCSI bus, with the <code>esp</code> host adapter plugged into slot 0.
<i>file</i>	Name of a standalone program to boot. If a filename is not explicitly specified, either on the <code>boot</code> command line or in the <i>boot-file</i> NVRAM variable, <code>boot</code> chooses an appropriate default filename. On most systems, the default filename is the 32-bit kernel. On systems capable of supporting both the 32-bit and 64-bit kernels, the 64-bit kernel will be chosen in preference to

		the 32-bit kernel. <code>boot</code> chooses an appropriate default <i>file</i> to boot based on what software is installed on the system, the capabilities of the hardware and firmware, and on a user configurable policy file.
-a		The boot program interprets this flag to mean <code>ask me</code> , and so it prompts for the name of the standalone. The <code>'-a'</code> flag is then passed to the standalone program.
-f		When booting an Autoclient system, this flag forces the boot program to bypass the client's local cache and read all files over the network from the client's file server. This flag is ignored for all non-Autoclient systems. The <code>-f</code> flag is then passed to the standalone program.
-V		Display verbose debugging information.
-D <i>default-file</i>		Explicitly specify the <i>default-file</i> . On some systems, <code>boot</code> chooses a dynamic default file, used when none is otherwise specified. This option allows the <i>default-file</i> to be explicitly set and can be useful when booting <code>kadb(1M)</code> since, by default, <code>kadb</code> loads the <i>default-file</i> as exported by the <code>boot</code> program.
<i>boot-flags</i>		The boot program passes all <i>boot-flags</i> to <i>file</i> . They are not interpreted by <code>boot</code> . See the <code>kernel(1M)</code> and <code>kadb(1M)</code> manual pages for information about the options available with the default standalone program.
<i>client-program-args</i>		The boot program passes all <i>client-program-args</i> to <i>file</i> . They are not interpreted by <code>boot</code> .
IA	<i>file</i>	Name of a standalone program to boot. The default is to boot <code>/platform/platform-name/kernel/unix</code> from the root partition, but you can specify another program on the command line.
	-f	When booting an Autoclient system, this flag forces the boot program to bypass the client's local cache and read all files over the network from the client's file server. This flag is ignored for all non-Autoclient systems. The <code>-f</code> flag is then passed to the standalone program.
	<i>boot-args</i>	The boot program passes all <i>boot-args</i> to <i>file</i> . They are not interpreted by <code>boot</code> . See <code>kernel(1M)</code> and <code>kadb(1M)</code> for information about the options available with the kernel.

**IA BOOT
SEQUENCE
DETAILS**

After a PC-compatible machine is turned on, the system firmware in the BIOS ROM executes a power-on self test (POST), runs BIOS extensions in peripheral board ROMs, and invokes software interrupt INT 19h, Bootstrap. The INT 19h handler typically performs the standard PC-compatible boot, which consists of trying to read the first

boot(1M)

IA Primary Boot

physical sector from the first diskette drive, or, if that fails, from the first hard disk. The processor then jumps to the first byte of the sector image in memory.

The first sector on a floppy disk contains the master boot block. The boot block is responsible for loading the image of the boot loader `strap.com`, which then loads the secondary boot, `boot.bin`. A similar sequence occurs for CD-ROM boot, but the master boot block location and contents are dictated by the El Torito specification. The El Torito boot also leads to `strap.com`, which in turn loads `boot.bin`.

The first sector on a hard disk contains the master boot block, which contains the master boot program and the FDISK table, named for the PC program that maintains it. The master boot finds the active partition in the FDISK table, loads its first sector, and jumps to its first byte in memory. This completes the standard PC-compatible hard disk boot sequence.

An IA FDISK partition for the Solaris software begins with a one-cylinder boot slice, which contains the partition boot program (`pboot`) in the first sector, the standard Solaris disk label and volume table of contents (VTOC) in the second and third sectors, and the `bootblk` program in the fourth and subsequent sectors. When the FDISK partition for the Solaris software is the active partition, the master boot program (`mboot`) reads the partition boot program in the first sector into memory and jumps to it. It in turn reads the `bootblk` program into memory and jumps to it. Regardless of the type of the active partition, if the drive contains multiple FDISK partitions, the user is given the opportunity to reboot another partition.

`bootblk` or `strap.com` (depending upon the active partition type) reads `boot.bin` from the file system in the Solaris root slice and jumps to its first byte in memory.

For network booting, you have the choice of the boot floppy or Intel's Preboot eXecution Environment (PXE) standard. When booting from the network using the boot floppy, you can select which network configuration strategy you want by editing the boot properties, changing the setting for `net-config-strategy`. By default, `net-config-strategy` is set to `rarp`. It can have two settings, `rarp` or `dhcp`. When booting from the network using PXE, the system or network adapter BIOS uses DHCP to locate a network bootstrap program (NBP) on a boot server and reads it using Trivial File Transfer Protocol (TFTP). The BIOS executes the NBP by jumping to its first byte in memory. The NBP uses DHCP to locate the secondary bootstrap on a boot server, reads it using TFTP, and executes it.

IA Secondary Boot

The secondary boot, `boot.bin`, switches the processor to 32-bit, paged, protected mode, and performs some limited machine initialization. It runs the Configuration Assistant program which either auto-boots the system, or presents a list of possible boot devices, depending on the state of the `auto-boot?` variable (see `eeprom(1M)`).

Disk target devices (including CDROM drives) are expected to contain UFS filesystems. Network devices can be configured to use either DHCP or Reverse Address Resolution Protocol (RARP) and `bootparams` RPC to discover the machine's IP address and which server will provide the root file system. The root file system is

	then mounted using NFS. After a successful root mount, <code>boot .bin</code> invokes a command interpreter, which interprets <code>/etc/bootrc</code> .
Secondary Boot Programming Language for IA	The wide range of hardware that must be supported on IA based systems demands great flexibility in the booting process. This flexibility is achieved in part by making the secondary boot programmable. The secondary boot contains an interpreter that accepts a simple command language similar to those of <code>sh</code> and <code>csh</code> . The primary differences are that pipelines, loops, standard output, and output redirection are not supported.
IA Lexical Structure	<p>The boot interpreter splits input lines into words separated by blanks and tabs. The metacharacters are dollar sign (<code>\$</code>), single-quote (<code>'</code>), double-quote (<code>"</code>), number sign (<code>#</code>), new-line, and backslash (<code>\</code>). The special meaning of metacharacters can be avoided by preceding them with a backslash. A new-line preceded by a backslash is treated as a blank. A number sign introduces a comment, which continues to the next new-line.</p> <p>A string enclosed in a pair of single-quote or double-quote characters forms all or part of a single word. White space and new-line characters within a quoted string become part of the word. Characters within a quoted string can be quoted by preceding them with a backslash character; thus a single-quote character can appear in a single-quoted string by preceding it with a backslash. Two backslashes produce a single backslash, and a new-line preceded by a backslash produces a new-line in the string.</p>
IA Variables	<p>The boot maintains a set of variables, each of which has a string value. The first character of a variable name must be a letter, and subsequent characters can be letters, digits, or underscores. The <code>set</code> command creates a variable and/or assigns a value to it, or displays the values of variables. The <code>unset</code> command deletes a variable.</p> <p>Variable substitution is performed when the interpreter encounters a dollar-sign that is not preceded by a backslash. The variable name following the dollar sign is replaced by the value of the variable, and parsing continues at the beginning of the value. Variable substitution is performed in double-quoted strings, but not in single-quoted strings. A variable name can be enclosed in braces to separate it from following characters.</p>
IA Commands	A command is a sequence of words terminated by a new-line character. The first word is the name of the command and subsequent words are arguments to the command. All commands are built-in commands. Standalone programs are executed with the <code>run</code> command.
IA Conditional Execution of Commands	<p>Commands can be conditionally executed by surrounding them with the <code>if</code>, <code>elseif</code>, <code>else</code>, and <code>endif</code> commands:</p> <pre> if <i>expr1</i> . . . elseif <i>expr2</i> . . . elseif <i>expr3</i> . . . else </pre>

`endif` An `if` block may be embedded in other `if` blocks.

IA Expressions

The `set`, `if`, and `elseif` commands evaluate arithmetic expressions with the syntax and semantics of the C programming language. The `|`, `&&`, `|`, `^`, `&`, `==`, `!=`, `<`, `>`, `<=`, `>=`, `>>`, `<<`, `+`, `-`, `*`, `/`, `%`, `~`, and `!` operators are accepted, as are `(`, `)`, and comma. Signed 32-bit integer arithmetic is performed.

Expressions are parsed after the full command line has been formed. Each token in an expression must be a separate argument word, so blanks must separate all tokens on the command line.

Before an arithmetic operation is performed on an operand word, it is converted from a string to a signed 32-bit integer value. After an optional leading sign, a leading `0` produces octal conversion and a leading `0x` or `0X` produces hexadecimal conversion. Otherwise, decimal conversion is performed. A string that is not a legal integer is converted to zero.

Several built-in functions for string manipulation are provided. Built-in function names begin with a dot. String arguments to these functions are not converted to integers. To cause an operator, for example, `-`, to be treated as a string, it must be preceded by a backslash, and that backslash must be quoted with another backslash. Also be aware that a null string can produce a blank argument, and thus an expression syntax error. For example:

```
if .strneq ( ${usrarg}X , \- , 1 ) is the safe way to test whether the variable usrarg
starts with a -, even if it could be null.
```

IA I/O

The boot interpreter takes its input from the system console or from one or more files. The source command causes the interpreter to read a file into memory and begin parsing it. The console command causes the interpreter to take its input from the system console. Reaching EOF causes the interpreter to resume parsing the previous input source. CTRL-D entered at the beginning of console line is treated as EOF.

The `echo` command writes its arguments to the display. The `read` command reads the system console and assigns word values to its argument variables.

IA Debugging

The `verbose` command turns verbose mode on and off. In verbose mode, the interpreter displays lines from the current source file and displays the command as actually executed after variable substitution.

The `singlestep` command turns singlestep mode on and off. In singlestep mode, the interpreter displays `step ?` before processing the next command, and waits for keyboard input, which is discarded. Processing proceeds when ENTER is pressed. This allows slow execution in verbose mode.

IA Initialization	When the interpreter is first invoked by the boot, it begins execution of a compiled-in initialization string. This string typically consists of "source /etc/bootrc\n" to run the boot script in the root file system.
IA Communication With Standalone Programs	The boot passes information to standalone programs through arguments to the run command. A standalone program can pass information back to the boot by setting a boot interpreter variable using the <code>var_ops()</code> boot service function. It can also pass information to the kernel using the <code>setprop()</code> boot service function. The <code>whoami</code> property is set to the name of the standalone program.
IA Built-in Commands	<p><code>console</code> Interpret input from the console until CTRL-D.</p> <p><code>echo arg1 ...</code> Display the arguments separated by blanks and terminate with a new-line.</p> <p><code>echo -n arg1 ...</code> Display the arguments separated by blanks, but do not terminate with a new-line.</p> <p><code>getprop <i>propname varname</i></code> Assign the value of property <i>propname</i> to the variable <i>varname</i>. A property value of length zero produces a null string. If the property does not exist, the variable is not set.</p> <p><code>getproplen <i>propname varname</i></code> Assign the length in hexadecimal of the value of property <i>propname</i> to the variable <i>varname</i>. Property value lengths include the terminating null. If the property does not exist, the variable is set to 0xFFFFFFFF (-1).</p> <p><code>if <i>expr</i></code> If the expression <i>expr</i> is true, execute instructions to the next <code>elseif</code>, <code>else</code>, or <code>endif</code>. If <i>expr</i> is false, do not execute the instructions.</p> <p><code>elseif <i>expr</i></code> If the preceding <code>if</code> and <code>elseif</code> commands all failed, and <i>expr</i> is true, execute instructions to the next <code>elseif</code>, <code>else</code>, or <code>endif</code>. Otherwise, do not execute the instructions.</p> <p><code>else</code> If the preceding <code>if</code> and <code>elseif</code> commands all failed, execute instructions to the next <code>elseif</code>, <code>else</code>, or <code>endif</code>. Otherwise, do not execute the instructions.</p> <p><code>endif</code> Revert to the execution mode of the surrounding block.</p> <p><code>help</code> Display a help screen that contains summaries of all available boot shell commands.</p> <p><code>read <i>name1</i> ...</code> Read a line from the console, break it into words, and assign them as values to the variables <i>name1</i>, and so forth.</p>

boot(1M)

`readt time . . .`
Same as `read`, but timeout after `time` seconds.

`run name arg1 . . .`
Load and transfer control to the standalone program `name`, passing it `arg1` and further arguments.

`set`
Display all the current variables and their values.

`set name`
Set the value of the variable `name` to the null string.

`set name word`
Set the value of the variable `name` to `word`.

`set name expr`
Set the value of the variable `name` to the value of `expr`. `expr` must consist of more than one word. The value is encoded in unsigned hexadecimal, so that `-1` is represented by `0xFFFFFFFF`.

`setcolor`
Set the text mode display attributes. Allowable colors are `black`, `blue`, `green`, `cyan`, `red`, `magenta`, `brown`, `white`, `gray`, `lt_blue`, `lt_green`, `lt_cyan`, `lt_red`, `lt_magenta`, `yellow`, and `hi_white`.

`setprop propname word`
Set the value of the property `propname` to `word`.

`singlestep` or `singlestep on`
Turn on singlestep mode, in which the interpreter displays `step ?` before each command is processed, and waits for keyboard input. Press ENTER to execute the next command.

`singlestep off`
Turn off singlestep mode.

`source name`
Read the file `name` into memory and begin to interpret it. At EOF, return to the previous source of input.

`unset name`
Delete the variable `name`.

`verbose` or `verbose on`
Turn on verbose mode, which displays lines from source files and commands to be executed.

`verbose off`
Turn off verbose mode.

IA Built-in Functions

The following built-in functions are accepted within expressions:

<code>.strcmp(string1, string2)</code>	Returns an integer value that is less than, equal to, or greater than zero, as <i>string1</i> is lexicographically less than, equal to, or greater than <i>string2</i> .
<code>.strncmp(string1, string2, n)</code>	Returns an integer value that is less than, equal to, or greater than zero, as <i>string1</i> is lexicographically less than, equal to, or greater than <i>string2</i> . At most, <i>n</i> characters are compared.
<code>.streq(string1, string2)</code>	Returns true if <i>string1</i> is equal to <i>string2</i> , and false otherwise.
<code>.strneq(string1, string2, n)</code>	Returns true if <i>string1</i> is equal to <i>string2</i> , and false otherwise. At most, <i>n</i> characters are compared.
<code>.strfind(string, addr, n)</code>	Scans <i>n</i> locations in memory starting at <i>addr</i> , looking for the beginning of <i>string</i> . The <i>string</i> in memory need not be null-terminated. Returns true if <i>string</i> is found, and false otherwise. <code>.strfind</code> can be used to search for strings in the ROM BIOS and BIOS extensions that identify different machines and peripheral boards.

SPARC **EXAMPLE 1** To Boot the Default Kernel In Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, respond to the `ok` prompt with one of the following:

```
boot -as
```

```
boot disk3 -as
```

32-bit SPARC **EXAMPLE 2** To Boot `kadb` Specifying The 32-Bit Kernel As The Default File

To boot `kadb` specifying the 32-bit kernel as the default file:

```
boot kadb -D kernel/unix
```

EXAMPLE 3 To Boot the 32-Bit Kernel Explicitly

To boot the 32-bit kernel explicitly, the kernel file name should be specified. So, to boot the 32-bit kernel in single-user interactive mode, respond to the `ok` prompt with one of the following:

```
boot kernel/unix -as
```

```
boot disk3 kernel/unix -as
```

boot(1M)

	EXAMPLE 3 To Boot the 32-Bit Kernel Explicitly <i>(Continued)</i>
64-bit SPARC	EXAMPLE 4 To Boot the 64-Bit Kernel Explicitly To boot the 64-bit kernel explicitly, the kernel file name should be specified. So, to boot the 64-bit kernel in single-user interactive mode, respond to the ok prompt with one of the following: <pre>boot kernel/sparcv9/unix -as</pre> <pre>boot disk3 kernel/sparcv9/unix -as</pre> Refer to the NOTES section "Booting UltraSPARC Systems" before booting the 64-bit kernel using an explicit filename.
IA	EXAMPLE 5 To Boot the Default Kernel In Single-User Interactive Mode To boot the default kernel in single-user interactive mode, respond to the > prompt with one of the following: <pre>b -as</pre> <pre>b kernel/unix -as</pre>
FILES	<pre>/platform/<i>platform-name</i>/ufsboot</pre> second level program to boot from a disk or CD. <pre>/etc/inittab</pre> table in which the "initdefault" state is specified. <pre>/sbin/init</pre> program that brings the system to the "initdefault" state. <pre>/platform/<i>platform-name</i>/boot.conf</pre> <pre>/platform/<i>hardware-class-name</i>/boot.conf</pre> Primary and alternate pathnames for the boot policy file. Note that the policy file is not implemented on all platforms. <pre>/platform/<i>platform-name</i>/kernel/unix</pre> default program to boot system. <pre>/platform/<i>platform-name</i>/kernel/sparcv9/unix</pre> default program to boot system. See NOTES section "Booting UltraSPARC Systems."

System Administration Guide: Basic Administration

Sun Hardware Platform Guide

OpenBoot Command Reference Manual

WARNINGS The `boot` utility is unable to determine which files can be used as bootable programs. If the booting of a file that is not bootable is requested, the `boot` utility loads it and branches to it. What happens after that is unpredictable.

NOTES *platform-name* can be found using the `-i` option of `uname(1)`. *hardware-class-name* can be found using the `-m` option of `uname(1)`.

64-bit SPARC **Booting UltraSPARC Systems**

Certain platforms may need a firmware upgrade to run the 64-bit kernel. See the *Sun Hardware Platform Guide* for details. If the 64-bit kernel packages are installed and `boot` detects that the platform needs a firmware upgrade to run 64-bit, `boot` displays a message on the console and chooses the 32-bit kernel as the default file instead.

On systems containing 200MHz or lower UltraSPARC-1 processors, it is possible for a user to run a 64-bit program designed to exploit a problem that could cause a processor to stall. Since 64-bit programs cannot run on the 32-bit kernel, the 32-bit kernel is chosen as the default file on these systems.

The code sequence that exploits the problem is very unusual and is not likely to be generated by a compiler. Assembler code had to be specifically written to demonstrate the problem. It is highly unlikely that a legitimate handwritten assembler routine would use this code sequence.

Users willing to assume the risk that a user might accidentally or deliberately run a program that was designed to cause a processor to stall may choose to run the 64-bit kernel by modifying the `boot` policy file. Edit `/platform/platform-name/boot.conf` so that it contains an uncommented line with the variable named `ALLOW_64BIT_KERNEL_ON_UltraSPARC_1_CPU` set to the value `true` as shown in the example that follows:

```
ALLOW_64BIT_KERNEL_ON_UltraSPARC_1_CPU=true
```

For more information, see the *Sun Hardware Platform Guide*.

IA Only Because the “-” key on national language keyboards has been moved, an alternate key must be used to supply arguments to the `boot` command on an IA based system

boot(1M)

using these keyboards. Use the “-” on the numeric keypad. The specific language keyboard and the alternate key to be used in place of the “-” during bootup is shown below.

Keyboard	Substitute Key
Italy	'
Spain	'
Sweden	+
France	?
Germany	?

For example, `b -r` would be typed as `b +r` on Swedish keyboards, although the screen display will show as `b -r`.

NAME	bsmconv, bsmunconv – enable or disable the Basic Security Module (BSM) on Solaris
SYNOPSIS	<pre>/etc/security/bsmconv [rootdir...]</pre> <pre>/etc/security/bsmunconv [rootdir...]</pre>
DESCRIPTION	<p>The <code>bsmconv</code> and <code>bsmunconv</code> scripts are used to enable or disable the BSM features on a Solaris system. The optional argument <code>rootdir</code> is a list of one or more root directories of diskless clients which have already been configured by way of the Host Manager, see <code>admintool(1M)</code></p> <p>To enable or disable BSM on a diskless client, a server, or a stand-alone system, logon as super-user to the system being converted and use the <code>bsmconv</code> or <code>bsmunconv</code> commands without any options.</p> <p>To enable or disable BSM on a diskless client from that client's server, logon to the server as super-user and use <code>bsmconv</code>, specifying the root directory of each diskless client you wish to affect. For example, the command:</p> <pre>myhost# bsmconv /export/root/client1 /export/root/client2</pre> <p>enables BSM on the two machines named <code>client1</code> and <code>client2</code>. While the command:</p> <pre>myhost# bsmconv</pre> <p>enables BSM only on the machine called <code>myhost</code>. It is no longer necessary to enable BSM on both the server and its diskless clients.</p> <p>After running <code>bsmconv</code> the system can be configured by editing the files in <code>/etc/security</code>. Each diskless client has its own copy of configuration files in its root directory. You might want to edit these files before rebooting each client.</p> <p>Following the completion of either script, the affected system(s) should be rebooted to allow the auditing subsystem to come up properly initialized.</p>
FILES	<p>The following files are created by <code>bsmconv</code>:</p> <pre>/etc/security/device_maps</pre> <p>Administrative file defining the mapping of device special files to allocatable device names.</p> <pre>/etc/security/device_allocate</pre> <p>Administrative file defining parameters for device allocation.</p>
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	busstat – report bus-related performance statistics
SYNOPSIS	<pre>busstat -e <i>device-inst</i> -h -l</pre> <pre>busstat [-a] [-n] [-w <i>device-inst</i> [,pic0=<i>event</i>,picn=<i>event</i>]]... [-r</pre> <pre> <i>device-inst</i>]... [<i>interval</i> [<i>count</i>]]</pre>
DESCRIPTION	<p>busstat provides access to the bus-related performance counters in the system. These performance counters allow for the measurement of statistics like hardware clock cycles, bus statistics including DMA and cache coherency transactions on a multiprocessor system. Each bus device that supports these counters can be programmed to count a number of events from a specified list. Each device supports one or more Performance Instrumentation Counters (PIC) that are capable of counting events independently of each other.</p> <p>Separate events can be selected for each PIC on each instance of these devices. busstat summarizes the counts over the last interval seconds, repeating forever. If a count is given, the statistics are repeated count times.</p> <p>Only root users can program these counters. Non-root users have the option of reading the counters that have been programmed by a root user.</p> <p>The default value for the <i>interval</i> argument is 1 second, and the default <i>count</i> is unlimited.</p> <p>The devices that export these counters are highly platform-dependent and the data may be difficult to interpret without an in-depth understanding of the operation of the components that are being measured and of the system they reside in.</p>
OPTIONS	<p>The following options are supported:</p> <p>-a Display absolute counter values. The default is delta values.</p> <p>-e <i>device-inst</i> Display the list of events that the specified device supports for each pic.</p> <p>Specify <i>device-inst</i> as device (name) followed by an optional instance number. If an instance number is specified, the events for that instance are displayed. If no instance number is specified, the events for the first instance of the specified device are displayed.</p> <p>-h Print a usage message.</p> <p>-l List the devices in the system which support performance counters.</p> <p>-n Do not display a title in the output. The default is to display titles.</p>

busstat(1M)

`-r device-inst`

Read and display all pic values for the specified device

Specify *device-inst* as *device* (name) followed by *instance number*, if specifying an instance number of a device whose counters are to be read and displayed. If all instances of this device are to be read, use *device* (name) without an instance number. All pic values will be sampled when using the `-r` option.

`-w device-inst [pic0=event] [picn=event]`

Program (write) the specified devices to count the specified events. Write access to the counters is restricted to root users only. Non-root users can use `-r` option.

Specify *device-inst* as *device* (name) followed by an optional *instance number*. If specifying an instance number of a device to program these events on. If all instances of this device are to be programmed the same, then use *device* without an instance number. Specify an event to be counted for a specified pic by providing a comma separated list of *picn=event* values.

The `-e` option displays all valid event names for each device. Any devices that are programmed will be sampled every interval seconds and repeated count times. It is recommended that the interval specified is small enough to ensure that counter wraparound will be detected. The rate at which counters wraparound varies from device to device. If a user is programming events using the `-w` option and `busstat` detects that another user has changed the events that are being counted, the tool will terminate as the programmed devices are now being controlled by another user. Only one user can be programming a device instance at any one time. Extra devices can be sampled using the `-r` option. Using multiple instances of the `-w` option on the same command line, with the same *device-inst* specifying a different list of events for the pics will give the effect of multiplexing for that device. `busstat` will switch between the list of events for that device every interval seconds. Event can be a string representing the event name, or even a number representing the bit pattern to be programmed into the Performance Control Register (PCR). This assumes explicit knowledge of the meaning of the control register bits for a device. The number can be specified in hexadecimal, decimal, or octal, using the usual conventions of `strtol(3C)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Another user is writing to the same devices.

SPARC Only

EXAMPLE 1 Programming and monitoring the Address Controller counters

In this example, `ac0` refers to the Address Controller instance 0. The counters are programmed to count Memory Bank stalls on an Ultra Enterprise system at 10 second intervals with the values displayed in absolute form instead of deltas.

EXAMPLE 1 Programming and monitoring the Address Controller counters *(Continued)*

```
# busstat -a -w ac0,pic0=mem_bank0_stall,pic1=mem_bank1_stall 10
time dev  event0          pic0  event1          pic1
10  ac0  mem_bank0_stall  1234  mem_bank1_stall  5678
20  ac0  mem_bank0_stall  5678  mem_bank1_stall  12345
30  ac0  mem_bank0_stall  12345  mem_bank1_stall  56789
...
```

For a complete list of the supported events for a device, use the `-e` option.

EXAMPLE 2 Programming and monitoring the counters on all instances of the Address Controller

In this example, `ac` refers to all `ac` instances. This example programs all instances of the Address Controller counters to count `_clock` cycles and `mem_bank0_rds` at 2 second intervals, 100 times, displaying the values as deltas.

```
# busstat -w ac,pic0=clock_cycles,pic1=mem_bank0_rds 2 100
time dev  event0          pic0  event1          pic1
2    ac0  clock_cycles    167242902  mem_bank0_rds  3144
2    ac1  clock_cycles    167254476  mem_bank0_rds  1392
4    ac0  clock_cycles    168025190  mem_bank0_rds  40302
4    ac1  clock_cycles    168024056  mem_bank0_rds  40580
...
```

EXAMPLE 3 Monitoring the events being counted

This example monitors the events that are being counted on the `sbus1` device, 100 times at 1 second intervals. It suggests that a root user has changed the events that `sbus1` was counting to be `dvma_tlb_misses` and `interrupts` instead of `pio_cycles`.

```
% busstat -r sbus0 1 100

time  dev  event0          pic0  event1          pic1
1     sbus1  pio_cycles      2321  pio_cycles      2321
2     sbus1  pio_cycles      48    pio_cycles      48
3     sbus1  pio_cycles      49    pio_cycles      49
4     sbus1  pio_cycles      2281  pio_cycles      2281
5     sbus1  dvma_tlb_misses  0     interrupts      0
6     sbus1  dvma_tlb_misses  6     interrupts      2
7     sbus1  dvma_tlb_misses  8     interrupts      11
...
```

EXAMPLE 4 Event Multiplexing

This example programs `ac0` to alternate between counting (clock cycles, `mem_bank0_rds`) and (`addr_pkts`, `data_pkts`) at 2 second intervals while also monitoring what `ac1` is counting :

busstat(1M)

EXAMPLE 4 Event Multiplexing (Continued)

It shows the expected output of the above `busstat` command. Another root user on the machine has changed the events that this user had programmed and `busstat` has detected this and terminates the command with a message.

```
# busstat -w ac0,pic0=clock_cycles,pic1=mem_bank0_rds \  
          -w ac0,pic0=addr_pkts,pic1=data_pkts \  
          -r ac1 2  
  
time    dev    event0          pic0          event1         pic1  
2       ac0    addr_pkts       12866         data_pkts      17015  
2       ac1    rio_pkts        385           rio_pkts        385  
4       ac0    clock_cycles    168018914     mem_bank0_rds  2865  
4       ac1    rio_pkts        506           rio_pkts        506  
6       ac0    addr_pkts       144236        data_pkts      149223  
6       ac1    rio_pkts        522           rio_pkts        522  
8       ac0    clock_cycles    168021245     mem_bank0_rds  2564  
8       ac1    rio_pkts        387           rio_pkts        387  
10      ac0    addr_pkts       144292        data_pkts      159645  
10      ac1    rio_pkts        506           rio_pkts        506  
12      ac0    clock_cycles    168020364     mem_bank0_rds  2665  
12      ac1    rio_pkts        522           rio_pkts        522  
busstat: events changed (possibly by another busstat).  
#
```

NAME	cachefsd – CacheFS daemon				
SYNOPSIS	<code>/usr/lib/fs/cacheefs/cachefsd</code>				
DESCRIPTION	<p>The <code>cachefsd</code> server implements features of the cache filesystem (CacheFS). It is invoked at boot time and run if the <code>/</code> (root) and <code>/usr</code> filesystems are being cached. If <code>/usr</code> is being cached, <code>cachefsd</code> is invoked by <code>inetd(1M)</code> from <code>inetd.conf(4)</code>. At run time, <code>cachefsd</code> is invoked by the <code>inetd</code> mechanism in response to an RPC request from a user command such as <code>mount_cacheefs(1M)</code>.</p> <p>The <code>cachefsd</code> server supports the “disconnected mode” of CacheFS. In this mode, a user can continue to read and, depending on the option selected, write to files in a cached filesystem when the NFS server for the cached files is not available.</p> <p>The <code>cachefsd</code> daemon performs the following functions in support of the CacheFS:</p> <ul style="list-style-type: none"> ■ Implements the connection policy. The daemon determines whether the NFS server backing the cache is connected or disconnected from the cache, or is in transition from the connected or disconnected states. ■ Implements “log rolling,” wherein the daemon monitors a disconnected NFS server for reconnection. After such a server returns to a connected state, <code>cachefsd</code> rolls any local changes to cached files (kept in a log) back to the server. ■ Manages “packing,” wherein <code>cachefsd</code> makes a best effort to ensure that files in a user-specified list are available in the cache in disconnected mode. ■ Supports user interfaces by supplying statistics, reporting conflicts between the cache and the back filesystem, and supporting a list of files for packing. <p>The running of <code>cachefsd</code> is required for the disconnected mode of CacheFS.</p>				
OPTIONS	<code>-r</code> Used for invoking <code>cachefsd</code> for the <code>/</code> filesystem.

cachefslog(1M)

NAME	<code>cachefslog</code> – Cache File System logging
SYNOPSIS	<code>cachefslog</code> [-f <i>logfile</i> -h] <i>cachefs_mount_point</i>
DESCRIPTION	The <code>cachefslog</code> command displays where CacheFS statistics are being logged. Optionally, it sets where CacheFS statistics are being logged, or it halts logging for a cache specified by <i>cachefs_mount_point</i> . The <i>cachefs_mount_point</i> argument is a mount point of a cache file system. All file systems cached under the same cache as <i>cachefs_mount_point</i> will be logged.
OPTIONS	The following options are supported. You must be super-user to use the -f and -h options. -f <i>logfile</i> Specify the log file to be used. -h Halt logging.
OPERANDS	<i>cachefs_mount_point</i> A mount point of a cache file system.
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>cachefslog</code> when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
EXAMPLES	<p>EXAMPLE 1 Checking the Logging of a directory.</p> <p>The example below checks if the directory <code>/home/sam</code> is being logged:</p> <pre>example% cachefslog /home/sam not logged: /home/sam</pre> <p>EXAMPLE 2 Changing the <i>logfile</i>.</p> <p>The example below changes the <i>logfile</i> of <code>/home/sam</code> to <code>/var/tmp/samlog</code>:</p> <pre>example# cachefslog -f /var/tmp/samlog /home/sam /var/tmp/samlog: /home/sam</pre> <p>EXAMPLE 3 Verifying the change of a <i>logfile</i>.</p> <p>The example below verifies the change of the previous example:</p> <pre>example% cachefslog /home/sam /var/tmp/samlog: /home/sam</pre> <p>EXAMPLE 4 Halting the logging of a directory.</p> <p>The example below halts logging for the <code>/home/sam</code> directory:</p> <pre>example# cachefslog -h /home/sam not logged: /home/sam</pre>
EXIT STATUS	The following exit values are returned: 0 success

non-zero an error has occurred.

DIAGNOSTICS `Invalid path` It is illegal to specify a path within a cache file system.

cachefspack(1M)

NAME	<code>cachefspack</code> – pack files and file systems in the cache
SYNOPSIS	<code>cachefspack</code> [-h] [-i -p -u] [-f <i>packing-list</i>] [-U <i>cache-directory</i>] [<i>file...</i>]
DESCRIPTION	The <code>cachefspack</code> utility is used to set up and maintain files in the cache. This utility affords greater control over the cache, ensuring that the specified files will be in the cache whenever possible.
OPTIONS	The following options are supported: -f <i>packing-list</i> Specify a file containing a list of files and directories to be packed. Options within subdirectories and files can also be specified. The format and rules governing <i>packing-list</i> are described on the <code>packingrules(4)</code> manual page. Directories are packed recursively. Symlinks that match a regular expression on a <code>LIST</code> command are followed. Symlinks encountered while recursively processing directories are not followed. -h Help. Print a brief summary of all the options. -i View information about the packed files. -p Pack the file or files specified by <i>file</i> . This is the default behavior. -u Unpack the file or files specified by <i>file</i> . -U <i>cache-directory</i> Unpack all files in the specified cache directory.
OPERANDS	The following operands are supported: <i>file</i> A path name of a file to be packed or unpacked.
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>cachefspack</code> when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
EXAMPLES	EXAMPLE 1 The following example packs the file <code>projects</code> in the cache. % <code>cachefspack -p projects</code> EXAMPLE 2 The following example packs the files <code>projects</code> , <code>updates</code> , and <code>master_plan</code> in the cache. % <code>cachefspack -p projects updates master_plan</code> EXAMPLE 3 The following example unpacks the file <code>projects</code> from the cache. % <code>cachefspack -u projects</code>

EXAMPLE 4 The following example unpacks the files `projects`, `updates`, and `master_plan` from the cache.

```
% cachefspack -u projects updates master_plan
```

EXAMPLE 5 The following example unpacks all files in the cache directory `cache1`.

```
% cachefspack -U /cache/cache1
```

EXAMPLE 6 The following example illustrates the use of a packing list to specify files to be packed in the cache. The contents of `lists.pkg` are as follows:

```
IGNORE SCCS BASE /src/junk LIST *.c LIST *.h
```

This example will pack all files in the directory `/src/junk` with `.c` and `.h` extensions that do not contained the string `SCCS` in the file's path name.

```
% cachefspack -f lists.pkg
```

EXIT STATUS

0 Successful completion.

>0 An error occurred.

cachefsstat(1M)

NAME	cachefsstat – Cache File System statistics						
SYNOPSIS	<code>/usr/bin/cachefsstat [-z] [path...]</code>						
DESCRIPTION	<p>The <code>cachefsstat</code> command displays statistical information about the cache file system mounted on <i>path</i>. The statistical information includes cache hits and misses, consistency checking, and modification operations. If <i>path</i> is not specified, all mounted cache file systems are used.</p> <p><code>cachefsstat</code> can also be used to reinitialize this information (see <code>-z</code> option).</p> <p>The statistical information has the following format:</p> <pre><cache hit rate> <consistency checks> <modifies></pre> <p>where:</p> <table><tr><td><i>hit rate</i></td><td>The percentage of cache hits over the total number of attempts, followed by the actual numbers of hits and misses.</td></tr><tr><td><i>consistency checks</i></td><td>The number of consistency checks performed, followed by the number that passed, and the number that failed.</td></tr><tr><td><i>modifies</i></td><td>The number of modify operations, including writes, creates, etc.</td></tr></table>	<i>hit rate</i>	The percentage of cache hits over the total number of attempts, followed by the actual numbers of hits and misses.	<i>consistency checks</i>	The number of consistency checks performed, followed by the number that passed, and the number that failed.	<i>modifies</i>	The number of modify operations, including writes, creates, etc.
<i>hit rate</i>	The percentage of cache hits over the total number of attempts, followed by the actual numbers of hits and misses.						
<i>consistency checks</i>	The number of consistency checks performed, followed by the number that passed, and the number that failed.						
<i>modifies</i>	The number of modify operations, including writes, creates, etc.						
OPTIONS	<p>The following option is supported:</p> <p><code>-z</code> Zero (reinitialize) statistics. Execute <code>cachefsstat -z</code> before executing <code>cachefsstat</code> again to gather statistics on the cache performance. This option can only be use by the superuser. The statistics printed reflect those just before the statistics are reinitialized.</p>						
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>cachefsstat</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).						
EXAMPLES	<p>EXAMPLE 1 Example of <code>cachefsstat</code>.</p> <pre>example% cachefsstat /home/sam cache hit rate: 73% (1234 hits, 450 misses) consistency checks: 700 (650 pass, 50 fail) modifies: 321</pre>						
EXIT STATUS	<p>The following exit values are returned:</p> <table><tr><td>0</td><td>success</td></tr><tr><td>non-zero</td><td>an error has occurred.</td></tr></table>	0	success	non-zero	an error has occurred.		
0	success						
non-zero	an error has occurred.

cachefswssize(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO cachefslog(1M), cachefsstat(1M), cfsadmin(1M), attributes(5), largefile(5)

DIAGNOSTICS problems were encountered writing log file
There were problems encountered when the kernel was writing the logfile. The most common problem is running out of disk space.

invalid log file
The logfile is not a valid logfile or was created with a newer version of Solaris than the one where cachefswssize is running.

captoinfo(1M)

NAME	captoinfo – convert a termcap description into a terminfo description				
SYNOPSIS	captoinfo [-1] [-v...] [-V] [-w <i>width</i>] <i>filename</i> ...				
DESCRIPTION	<p>captoinfo looks in <i>filename</i> for termcap descriptions. For each one found, an equivalent terminfo description is written to standard output, along with any comments found. A description which is expressed as relative to another description (as specified in the termcap <code>tc = field</code>) is reduced to the minimum superset before being displayed.</p> <p>If no <i>filename</i> is given, then the environment variable <code>TERMCAP</code> is used for the filename or entry. If <code>TERMCAP</code> is a full pathname to a file, only the terminal whose name is specified in the environment variable <code>TERM</code> is extracted from that file. If the environment variable <code>TERMCAP</code> is not set, then the file <code>/usr/share/lib/termcap</code> is read.</p>				
OPTIONS	<p>-1 Display the fields one to a line. Otherwise, the fields are printed several to a line, with a maximum width of 60 characters.</p> <p>-v Display tracing information on the standard error as the program runs. Specifying additional -v options displays more detailed information.</p> <p>-V Display the version of the program in use on the standard error and then exit.</p> <p>-w <i>width</i> Change the output to <i>width</i> characters.</p>				
FILES	<p><code>/usr/share/lib/terminfo/??/*</code> compiled terminal description database</p> <p><code>/usr/share/lib/termcap</code></p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>infocmp(1M)</code> , <code>curses(3CURSES)</code> , <code>terminfo(4)</code> , <code>attributes(5)</code>				
NOTES	captoinfo should be used to convert termcap entries to terminfo entries because the termcap database may not be supplied in future releases.				

NAME	catman – create the formatted files for the reference manual
SYNOPSIS	<code>/usr/bin/catman [-c] [-n] [-p] [-t] [-w] [-M <i>directory</i>]</code> <code>[-T <i>macro-package</i>] [<i>sections</i>]</code>
DESCRIPTION	<p>The <code>catman</code> utility creates the preformatted versions of the on-line manual from the <code>nroff(1)</code> or <code>sgml(5)</code> input files. This feature allows easy distribution of the preformatted manual pages among a group of associated machines (for example, with <code>rdist(1)</code>), since it makes the directories of preformatted manual pages self-contained and independent of the unformatted entries.</p> <p><code>catman</code> also creates the <code>windex</code> database file in the directories specified by the <code>MANPATH</code> or the <code>-M</code> option. The <code>windex</code> database file is a three column list consisting of a keyword, the reference page that the keyword points to, and a line of text that describes the purpose of the utility or interface documented on the reference page. Each keyword is taken from the comma separated list of words on the <code>NAME</code> line before the ‘-’ (dash). The reference page that the keyword points to is the first word on the <code>NAME</code> line. The text after the – on the <code>NAME</code> line is the descriptive text in the third column. The <code>NAME</code> line must be immediately preceded by the page heading line created by the <code>.TH</code> macro (see <code>NOTES</code> for required format).</p> <p>Each manual page is examined and those whose preformatted versions are missing or out of date are recreated. If any changes are made, <code>catman</code> recreates the <code>windex</code> database.</p> <p>If a manual page is a <i>shadow</i> page, that is, it sources another manual page for its contents, a symbolic link is made in the <code>catx</code> or <code>fmtx</code> directory to the appropriate preformatted manual page.</p> <p>Shadow files in an unformatted <code>nroff</code> source file are identified by the first line being of the form <code>.so manx/yyy.x</code>.</p> <p>Shadow files in the <code>SGML</code> sources are identified by the string <code>SHADOW_PAGE</code>. The file entity declared in the shadow file identifies the file to be sourced.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-c</code> Create unformatted <code>nroff</code> source files in the appropriate <code>man</code> subdirectories from the <code>SGML</code> sources. This option will overwrite any existing file in the <code>man</code> directory of the same name as the <code>SGML</code> file. <code>-n</code> Do not create (or recreate) the <code>windex</code> database. If the <code>-n</code> option is specified, the <code>windex</code> database is not created and the <code>apropos</code>, <code>whatis</code>, <code>man -f</code>, and <code>man -k</code> commands will fail. <code>-p</code> Print what would be done instead of doing it.

catman(1M)

-t	Create <code>troffed</code> entries in the appropriate <code>fmt</code> subdirectories instead of <code>nroffing</code> into the <code>cat</code> subdirectories.
-w	Only create the <code>windex</code> database that is used by <code>whatis(1)</code> and the <code>man(1)</code> <code>-f</code> and <code>-k</code> options. No manual reformatting is done.
-M <i>directory</i>	Update manual pages located in the specified <i>directory</i> , (<code>/usr/share/man</code> by default). If the <code>-M</code> option is specified, the directory argument must not contain a <code>,</code> (comma), since a comma is used to delineate section numbers. See <code>man(1)</code> .
-T <i>macro-package</i>	Use <i>macro-package</i> in place of the standard manual page macros, (<code>man(5)</code> by default).

OPERANDS The following operand is supported:

sections If there is one parameter not starting with a `'-`, it is taken to be a space separated list of manual sections to be processed by `catman`. If this operand is specified, only the manual sections in the list will be processed. For example,

```
catman 1 2 3
```

only updates manual sections 1, 2, and 3. If specific sections are not listed, all sections in the `man` directory specified by the environment variable `MANPATH` are processed.

ENVIRONMENT VARIABLES

`TROFF` The name of the formatter to use when the `-t` flag is given. If not set, `troff(1)` is used.

`MANPATH` A colon-separated list of directories that are processed by `catman` and `man(1)`. Each directory can be followed by a comma-separated list of sections. If set, its value overrides `/usr/share/man` as the default directory search path, and the `man.cf` file as the default section search path. The `-M` and `-s` flags, in turn, override these values.

FILES

<code>/usr/share/man</code>	default manual directory location
<code>/usr/share/man/man*/**.*</code>	raw <code>nroff</code> input files
<code>/usr/share/man/sman*/**.*</code>	raw SGML input files
<code>/usr/share/man/cat*/**.*</code>	preformatted <code>nroffed</code> manual pages
<code>/usr/share/man/fmt*/**.*</code>	preformatted <code>troffed</code> manual pages
<code>/usr/share/man/windex</code>	table of contents and keyword database
<code>/usr/lib/makewhatis</code>	command script to make <code>windex</code> database
<code>/usr/share/lib/tmac/an</code>	default macro package

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc
CSI	Enabled

SEE ALSO `apropos(1)`, `man(1)`, `nroff(1)`, `rdist(1)`, `rm(1)`, `troff(1)`, `whatis(1)`, `attributes(5)`, `man(5)`, `sgml(5)`

DIAGNOSTICS `man?/xxx.? (.so'ed from man?/yyy.?)`: No such file or directory
The file outside the parentheses is missing, and is referred to by the file inside them.

`target of .so in man?/xxx.? must be relative to /usr/man`
catman only allows references to filenames that are relative to the directory `/usr/man`.

`opendir:man?`: No such file or directory
A harmless warning message indicating that one of the directories catman normally looks for is missing.

`*.*`: No such file or directory
A harmless warning message indicating catman came across an empty directory.

WARNINGS If a user, who has previously run catman to install the `cat*` directories, upgrades the operating system, the entire `cat*` directory structure should be removed prior to running catman. See `rm(1)`.

Do not re-run catman to re-build the `whatis` database unless the complete set of `man*` directories is present. catman builds this `windex` file based on the `man*` directories.

NOTES To generate a valid `windex` index file, catman has certain requirements. Within the individual man page file, catman requires two macro lines to have a specific format. These are the `.TH` page heading line and the `.SH NAME` line.

The `.TH` macro requires at least the first three arguments, that is, the filename, section number, and the date. The `.TH` line starts off with the `.TH` macro, followed by a space, the man page filename, a single space, the section number, another single space, and the date. The date should appear in double quotes and is specified as "day month year," with the month always abbreviated to the first three letters (Jan, Feb, Mar, and so forth).

The `.SH NAME` macro, also known as the `NAME` line, must immediately follow the `.TH` line, with nothing in between those lines. No font changes are permitted in the `NAME` line. The `NAME` line is immediately followed by a line containing the man page

catman(1M)

filename; then shadow page names, if applicable, separated by commas; a dash; and a brief summary statement. These elements should all be on one line; no carriage returns are permitted.

An example of proper coding of these lines is:

```
.TH nismatch 1M "10 Apr 1998"  
.SH NAME  
nismatch, nisgrep \- utilities for searching NIS+ tables
```

NAME	cfgadm – configuration administration
SYNOPSIS	<pre> /usr/sbin/cfgadm [-f] [-y -n] [-v] [-o hardware_options] -c function ap_id... /usr/sbin/cfgadm [-f] [-y -n] [-v] [-o hardware_options] -x hardware_function ap_id... /usr/sbin/cfgadm [-v] [-a] [-s listing_options] [-o hardware_options] [-l [ap_id ap_type]] /usr/sbin/cfgadm [-v] [-o hardware_options] -t ap_id... /usr/sbin/cfgadm [-v] [-o hardware_options] -h [ap_id ap_type] </pre>
DESCRIPTION	<p>The <code>cfgadm</code> command provides configuration administration operations on dynamically reconfigurable hardware resources. These operations include displaying status, (<code>-l</code>), initiating testing, (<code>-t</code>), invoking configuration state changes, (<code>-c</code>), invoking hardware specific functions, (<code>-x</code>), and obtaining configuration administration help messages (<code>-h</code>). Configuration administration is performed at <i>attachment points</i>, which are places where system software supports dynamic reconfiguration of hardware resources during continued operation of Solaris.</p> <p>Configuration administration makes a distinction between hardware resources that are physically present in the machine and hardware resources that are configured and visible to Solaris. The nature of configuration administration functions are hardware specific, and are performed by calling hardware specific libraries.</p> <p>Configuration administration operates on an <i>attachment point</i>. Hardware resources located at attachment points can or can not be physically replaceable during system operation, but are dynamically reconfigurable by way of the configuration administration interfaces.</p> <p>An attachment point defines two unique elements, which are distinct from the hardware resources that exist beyond the attachment point. The two elements of an attachment point are a <i>receptacle</i> and an <i>occupant</i>. Physical insertion or removal of hardware resources occurs at attachment points and results in a receptacle gaining or losing an occupant. Configuration administration supports the physical insertion and removal operations as well as other configuration administration functions at an attachment point.</p> <p>Attachment points have associated state and condition information. The configuration administration interfaces provide control for transitioning attachment point states. A receptacle can exist in one of three states: <code>empty</code>, <code>disconnected</code> or <code>connected</code>, while an occupant can exist in one of two states: <code>configured</code> or <code>unconfigured</code>.</p> <p>A receptacle can provide the <code>empty</code> state, which is the normal state of a receptacle when the attachment point has no occupants. A receptacle can also provide the <code>disconnected</code> state if it has the capability of isolating its occupants from normal system access. Typically this state is used for various hardware specific testing prior to bringing the occupant's resources into full use by the system, or as a step in preparing</p>

an occupant for physical removal or reconfiguration. A receptacle in the `disconnected` state isolates its occupant from the system as much as its hardware allows, but can provide access for testing and setup. A receptacle must provide the `connected` state, which allows normal access to hardware resources contained on any occupants. The `connected` state is the normal state of a receptacle that contains an occupant and that is not currently undergoing configuration administration operations.

The hardware resources contained on an occupant in the `unconfigured` state are not represented by normal Solaris data structures and are thus not available for use by Solaris. Operations allowed on an unconfigured occupant are limited to configuration administration operations. The hardware resources of an occupant in the `configured` state are represented by normal Solaris data structures and thus some or all of those hardware resources can be in use by Solaris. All occupants provide both the `configured` and `unconfigured` states,

An attachment point can be in one of five conditions: `unknown`, `ok`, `failing`, `failed`, or `unusable`. An attachment point can enter the system in any condition depending upon results of power-on tests and non-volatile record keeping.

An attachment point with an occupant in the `configured` state is in one of four conditions: `unknown`, `ok`, `failing`, or `failed`. If the condition is not `failing` or `failed` an attachment point can change to `failing` during the course of operation if a hardware dependent recoverable error threshold is exceeded. If the condition is not `failed` an attachment point can change to `failed` during operation as a result of an unrecoverable error.

An attachment point with an occupant in the `unconfigured` state can be in any of the defined conditions. The condition of an attachment point with an `unconfigured` occupant can decay from `ok` to `unknown` after a machine dependent time threshold. Initiating a test function changes the attachment point's condition to `ok`, `failing` or `failed` depending on the outcome of the test. An attachment point that does not provide a test function can leave the attachment point in the `unknown` condition. If a test is interrupted, the attachment point's condition can be set to the previous condition, `unknown` or `failed`. An attachment point in the `unknown`, `ok`, `failing`, or `failed` conditions can be re-tested.

An attachment point can exist in the `unusable` condition for a variety of reasons, such as inadequate power or cooling for the receptacle, an occupant that is unidentifiable, unsupported, incorrectly configured, etc. An attachment point in the `unusable` condition can never be used by the system. It typically remains in this condition until the physical cause is remedied.

An attachment point also maintains busy information that indicates when a state change is in progress or the condition is being reevaluated.

Attachment points are referred to using hardware specific identifiers (*ap_ids*) that are related to the type and location of the attachment points in the system device hierarchy. An *ap_id* can not be ambiguous, it must identify a single attachment point.

Two types of *ap_id* specifications are supported: physical and logical. A physical *ap_id* contains a fully specified pathname, while a logical *ap_id* contains a shorthand notation that identifies an attachment point in a more user-friendly way.

For example, an attachment point representing a system's backplane slot number 7 could have a physical *ap_id* of `/devices/central/fhc/sysctrl:slot7` while the logical *ap_id* could be `system:slot7`. Another example, the third receptacle on the second PCI I/O bus on a system could have a logical *ap_id* of `pci2:plug3`.

Attachment points may also be created dynamically. A dynamic attachment point is named relative to a base attachment point which is present in the system. *ap_ids* for dynamic attachment points consist of a base component followed by two colons (`::`) and a dynamic component. The base component is the base attachment point *ap_id*. The dynamic component is hardware specific and generated by the corresponding hardware specific library.

For example, consider a base attachment point, which represents a SCSI HBA, with the physical *ap_id* `/devices/sbus@1f,0/SUNW,fas@e,8800000:scsi` and logical *ap_id* `c0`. A disk attached to this SCSI HBA could be represented by a dynamic attachment point with logical *ap_id* `c0::dsk/c0t0d0` where `c0` is the base component and `dsk/c0t0d0` is the hardware specific dynamic component. Similarly the physical *ap_id* for this dynamic attachment point would be:
`/devices/sbus@1f,0/SUNW,fas@e,8800000:scsi::dsk/c0t0d0`

An *ap_type* is a partial form of a logical *ap_id* that can be ambiguous and not specify a particular attachment point. An *ap_type* is a substring of the portion of the logical *ap_id* up to but not including the colon (`:`) separator. For example, an *ap_type* of `pci` would show all attachment points whose logical *ap_ids* begin with `pci`.

The use of *ap_types* is discouraged. The new `select` sub-option to the `-s` option provides a more general and flexible mechanism for selecting attachment points. See `OPTIONS`.

The `cfgadm` command interacts primarily with hardware dependent functions contained in hardware specific libraries and thus its behavior is hardware dependent.

For each configuration administration operation a service interruption can be required. Should the completion of the function requested require a noticeable service interruption to interactive users, a prompt is output on the standard error output for confirmation on the standard input before the function is started. Confirmation can be overridden using the `-y` or `-n` options to always answer yes or no respectively. Hardware specific options, such as test level, are supplied as sub-options using the `-o` option.

Operations that change the state of the system configuration are audited by the system log daemon `syslogd(1M)`.

The arguments for this command conform to the `getopt(3C)` and `getsubopt(3C)` syntax convention.

cfgadm(1M)

OPTIONS

The following options are supported:

-a

Specifies that the -l option must also list dynamic attachment points.

-c *function*

Performs the state change *function* on the attachment point specified by *ap_id*.

Specify *function* as *insert*, *remove*, *disconnect*, *connect*, *configure* or *unconfigure*. These functions cause state transitions at the attachment point by calling hardware specific library routines and are defined in the following list.

<i>insert</i>	Performs operations that allows the user to manually insert an occupant or to activate a hardware supplied mechanism that performs the physical insertion. <i>insert</i> can have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors can cause this function to fail and set the receptacle condition to unusable.
<i>remove</i>	Performs operations that allow the user to manually remove an occupant or to activate a hardware supplied mechanism to perform the physical removal. <i>remove</i> can have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors can cause this function to fail and set the receptacle condition to unusable.
<i>disconnect</i>	Performs hardware specific operations to put a receptacle in the disconnected state, which can prevent an occupant from operating in a normal fashion through the receptacle.
<i>connect</i>	Performs hardware specific operations to put the receptacle in the connected state, which allows an occupant to operate in a normal fashion through the receptacle.
<i>configure</i>	Performs hardware specific operations that allow an occupant's hardware resources to be usable by Solaris. Occupants that are configured are part of the system configuration and are available for manipulation by Solaris device manipulation maintenance commands (eg: <i>psradm(1M)</i> , <i>mount(1M)</i> , <i>ifconfig(1M)</i>).
<i>unconfigure</i>	Performs hardware specific operations that logically remove an occupant's hardware resources from the system. The occupant must currently be configured and its hardware resources must not be in use by Solaris.

State transition functions can fail due to the condition of the attachment point or other hardware dependent considerations. All state change *functions* in the direction of adding resources, (*insert*, *connect* and *configure*) are passed onto the hardware specific library when the attachment point is in the *ok* or *unknown* condition. All other conditions require the use of the force option to allow these *functions* to be passed on to the hardware specific library. Attachment point condition does not prevent a hardware specific library being called for related to the removal (*remove*, *disconnect* and *unconfigure*), of hardware resources from the system. Hardware specific libraries can reject state change *functions* if the attachment point is in the *unknown* condition.

The condition of an attachment point is not necessarily changed by the state change functions, however errors during state change operations can change the attachment point condition. An attempt to override a condition and force a state change that would otherwise fail can be made by specifying the force option (*-f*). Hardware specific safety and integrity checks can prevent the force option from having any effect.

-f

Forces the specified action to occur. Typically, this is a hardware dependent override of a safety feature. Forcing a state change operation can allow use of the hardware resources of occupant that is not in the *ok* or *unknown* conditions, at the discretion of any hardware dependent safety checks.

-h [ap_id | ap_type ...]

Prints out the help message text. If *ap_id* or *ap_type* is specified, the help routine of the hardware specific library for the attachment point indicated by the argument is called.

-l [ap_id | ap_type ...]

Lists the state and condition of attachment points specified. Attachment points can be filtered by using the *-s* option and *select* sub-option. Invoking *cfgadm* without one of the action options is equivalent to *-l* without an argument. The format of the list display is controlled by the *-v* and *-s* options. When the *-a* option is specified attachment points are dynamically expanded.

-n

Suppress any interactive confirmation and assume that the answer is *no*. If neither *-n* or *-y* is specified, interactive confirmation is obtained through the standard error output and the standard input. If either of these standard channels does not correspond to a terminal (as determined by *isatty(3C)*) then the *-n* option is assumed.

-o hardware_options

Supplies hardware specific options to the main command option. The format and content of the hardware option string is completely hardware specific. The option string *hardware_options* conforms to the *get.subopt(3C)* syntax convention.

-s listing_options

Supplies listing options to the list (-l) command. *listing_options* conforms to the getsubopt(3C) syntax convention. The sub-options are used to specify the attachment point selection criteria (*select=select_string*), the type of matching desired (*match=match_type*), order of listing (*sort=field_spec*), the data that is displayed (*cols=field_spec* and *cols2=field_spec*), the column delimiter (*delim=string*) and whether to suppress column headings (*noheadings*).

When the *select* sub-option is specified, only attachment points which match the specified criteria will be listed. The *select* suboption has the following syntax:

```
cfgadm -s select=attr1(value1):attr2(value2)...
```

where an *attr* is one of *ap_id*, *class* or *type*. *ap_id* refers to the logical *ap_id* field, *class* refers to attachment point class and *type* refers to the type field.

value1, *value2*, etc. are the corresponding values to be matched. The type of match can be specified by the *match* sub-option as follows:

```
cfgadm -s match=match_type,select=attr1(value1)...
```

where *match_type* can be either *exact* or *partial*. The default value is *exact*.

Arguments to the *select* suboption can be quoted to protect them from the shell.

A *field_spec* is one or more *data-fields* concatenated using colon (:), as in *data-field:data-field:data-field*. A *data-field* is one of *ap_id*, *physid*, *r_state*, *o_state*, *condition*, *type*, *busy*, *status_time*, *status_time_p*, *class*, and *info*. The *ap_id* field output is the logical name for the attachment point, while the *physid* field contains the physical name. The *r_state* field can be *empty*, *disconnected* or *connected*. The *o_state* field can be *configured* or *unconfigured*. The *busy* field can be either *y* if the attachment point is busy, or *n* if it is not. The *type* and *info* fields are hardware specific. The *status_time_p* field is a parsable version of the *status_time* field. If an attachment point has an associated class, the *class* field lists the class name. If an attachment point does not have an associated class, the *class* field lists *none*.

The order of the fields in *field_spec* is significant: For the *sort* sub-option, the first field given is the primary sort key. For the *cols* and *cols2* sub-options, the fields are printed in the order requested. The order of sorting on a *data-field* can be reversed by placing a minus (-) before the *data-field* name within the *field_spec* for the *sort* sub-option. The default value for *sort* is *ap_id*. The default values for *cols* and *cols2* depend on whether the *-v* option is given: Without it *cols* is *ap_id:r_state:o_state:condition* and *cols2* is not set. With *-v* *cols* is *ap_id:r_state:o_state:condition:info* and *cols2* is *status_time:type:busy:physid:.* The default value for *delim* is a single space. The value of *delim* can be a string of arbitrary length. The delimiter cannot include comma (,) character, see getsubopt(3C). These listing options can be used to create parsable output. See NOTES.

-t

Performs a test of one or more attachment points. The test function is used to re-evaluate the condition of the attachment point. Without a test level specifier in *hardware_options*, the fastest test that identifies hard faults is used.

More comprehensive tests are hardware specific and are selected using the *hardware_options*.

The results of the test is used to update the condition of the specified occupant to either `ok` if no faults are found, `failing` if recoverable faults are found or `failed` if any unrecoverable faults are found.

If a test is interrupted, the attachment point's condition can be restored to its previous value or set to `unknown` if no errors were found or `failing` if only recoverable errors were found or to `failed` if any unrecoverable errors were found. The attachment point should only be set to `ok` upon normal completion of testing with no errors.

-v

Executes in verbose mode. For the `-c`, `-t` and `-x` options outputs a message giving the results of each attempted operation. Outputs detailed help information for the `-h` option. Outputs verbose information for each attachment point for the `-l` option.

-x *hardware_function*

Performs hardware specific functions. Private hardware specific functions can change the state of a receptacle or occupant. Attachment point conditions can change as the result of errors encountered during private hardware specific functions. The format and content of the *hardware_function* string is completely hardware specific. The option string *hardware_function* conforms to the `getsubopt(3C)` syntax convention.

-y

Suppresses any interactive confirmation and assume that the answer is yes.

USAGE The required privileges to use this command are hardware dependent. Typically, a default system configuration restricts all but the list option to the superuser.

EXAMPLES **EXAMPLE 1** Listing attachment points in the device tree

The following example lists all attachment points except dynamic attachment points.

```
example# cfgadm
```

Ap_Id	Type	Receptacle	Occupant	Cond
system:slot0	cpu/mem	connected	configured	ok
system:slot1	sbus-upa	connected	configured	ok
system:slot2	cpu/mem	connected	configured	ok
system:slot3	unknown	connected	unconfigured	unknown
system:slot4	dual-sbus	connected	configured	failing
system:slot5	cpu/mem	connected	configured	ok
system:slot6	unknown	disconnected	unconfigured	unusable

EXAMPLE 1 Listing attachment points in the device tree (Continued)

```
system:slot7    unknown    empty          unconfigured    ok
c0              scsi-bus   connected      configured       unknown
c1              scsi-bus   connected      configured       unknown
```

EXAMPLE 2 Listing all configurable hardware information

The following example lists all current configurable hardware information, including those represented by dynamic attachment points:

```
example# cfgadm -al
```

Ap_Id	Type	Receptacle	Occupant	Cond
system:slot0	cpu/mem	connected	configured	ok
system:slot1	sbus-upa	connected	configured	ok
system:slot2	cpu/mem	connected	configured	ok
system:slot3	unknown	connected	unconfigured	unknown
system:slot4	dual-sbus	connected	configured	failing
system:slot5	cpu/mem	connected	configured	ok
system:slot6	unknown	disconnected	unconfigured	unusable
system:slot7	unknown	empty	unconfigured	ok
c0	scsi-bus	connected	configured	unknown
c0::dsk/c0t14d0	disk	connected	configured	unknown
c0::dsk/c0t11d0	disk	connected	configured	unknown
c0::dsk/c0t8d0	disk	connected	configured	unknown
c0::rmt/0	tape	connected	configured	unknown
c1	scsi-bus	connected	configured	unknown

EXAMPLE 3 Selective listing based on attachment point attributes

The following example lists all attachment points whose class begins with `scsi`, `ap_id` begins with `c` and `type` field begins with `scsi`. The argument to the `-s` option is quoted to protect it from the shell.

```
example# cfgadm -s "match=partial,select=class(scsi):ap_id(c):type(scsi)"
```

Ap_Id	Type	Receptacle	Occupant	Cond
c0	scsi-bus	connected	configured	unknown
c1	scsi-bus	connected	configured	unknown

EXAMPLE 4 Listing current configurable hardware information in verbose mode.

The following example lists current configurable hardware information for *ap-type* system in verbose mode:

```
example# cfgadm -v -l system
```

Ap_Id	Type	Receptacle	Occupant	Condition	Information
When	Type	Busy	Phys_Id		
system:slot1		connected	configured	ok	
Apr 4 23:50	sbus-upa	n	/devices/central/fhc/sysctrl:slot1		
system:slot3		connected	configured	ok	non-detachable
Apr 17 11:20	cpu/mem	n	/devices/central/fhc/sysctrl:slot3		

EXAMPLE 4 Listing current configurable hardware information in verbose mode.
(Continued)

```
system:slot5          connected configured ok
Apr  4 23:50 cpu/mem  n          /devices/central/fhc/sysctrl:slot5
system:slot7          connected configured ok
Apr  4 23:50 dual-sbus n          /devices/central/fhc/sysctrl:slot7
```

EXAMPLE 5 The hardware specific extended test.

The following example tests two occupants using the hardware specific extended test:

```
example# cfgadm -v -o extended -t system:slot3 system:slot5
Testing attachment point system:slot3 ... ok
Testing attachment point system:slot5 ... ok
```

EXAMPLE 6 The force option.

The following example configures an occupant in the failing state to the system using the force option:

```
example# cfgadm -f -c configure system:slot3
```

EXAMPLE 7 Unconfiguring an occupant from the system.

The following example unconfigures an occupant from the system:

```
example# cfgadm -c unconfigure system:slot4
```

EXAMPLE 8 Configuring an occupant at an attachment point

The following example configures an occupant:

```
example# cfgadm -c configure c0::dsk/c0t0d0
```

ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `cfgadm`: `LC_TIME`, `LC_MESSAGES`, `NLSPATH` and `TZ`.

- `LC_MESSAGES` Determines how `cfgadm` displays column headings and error messages. Listing output data is not affected by the setting of this variable.
- `LC_TIME` Determines how `cfgadm` displays human readable status changed time (`status_time`).
- `TZ` Specifies the timezone used when converting the status changed time. This applies to both the human readable (`status_time`) and parsable (`status_time_p`) formats.

EXIT STATUS

The following exit values are returned:

cfgadm(1M)

- 0 Successful completion.
- 1 An error occurred.
- 2 Configuration administration not supported on specified target.
- 3 Usage error.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `cfgadm_pci(1M)`, `cfgadm_sbd(1M)`, `cfgadm_scsi(1M)`, `ifconfig(1M)`, `mount(1M)`, `prtdiag(1M)`, `psradm(1M)`, `syslogd(1M)`, `config_admin(3CFGADM)`, `getopt(3C)`, `getsubopt(3C)`, `isatty(3C)`, `attributes(5)`, `environ(5)`,

DIAGNOSTICS Diagnostic messages appear on the standard error output. Other than options and usage errors, the following are diagnostic messages produced by this utility:

`cfgadm: Configuration administration not supported on ap_id`

`cfgadm: No library found for ap_id`

`cfgadm: ap_id is ambiguous`

`cfgadm: operation: Insufficient privileges`

`cfgadm: Attachment point is busy, try again`

`cfgadm: No attachment points with specified attributes found`

`cfgadm: System is busy, try again`

`cfgadm: operation: Operation requires a service interruption`

`cfgadm: operation: Data error: error_text`

`cfgadm: operation: Hardware specific failure: error_text`

See `config_admin(3CFGADM)` for additional details regarding error messages.

NOTES Hardware resources enter the unconfigured pool in a hardware specific manner. This can occur at various times such as: system initialization or as a result of an unconfigure operation. An occupant that is in the unconfigured state is not available for use by the system until specific intervention occurs. This intervention can be manifested as an operator initiated command or it can be by way of an automatic configuring mechanism.

The listing option of the `cfgadm` command can be used to provide parsable input for another command, for example within a shell script. For parsable output, the `-s`

option must be used to select the fields required. The `-s` option can also be used to suppress the column headings. The following fields always produce parsable output: `ap_id`, `physid`, `r_state`, `o_state`, `condition`, `busy`, `status_time_p`, `class`, and `type`. Parsable output never has white-space characters embedded in the field value.

The following shell script fragment finds the first good unconfigured occupant of type CPU.

```
found=
cfgadm -l -s "noheadings,cols=ap_id:r_state:condition:type" | \
while read ap_id r_state cond type
do
    if [ "$r_state" = unconfigured -a "$cond" = ok -a "$type" = CPU ]
    then
        if [ -z "$found" ]
        then
            found=$ap_id
        fi
    fi
done
if [ -n "$found" ]
then
    echo "Found CPU $found"
fi
```

The format of the parsable time field (`status_time_p`) is `YYYYMMDDhhmmss`, giving the year, month, day, hour, minute and second in a form suitable for string comparison.

Reference should be made to the hardware specific documentation for details of System Configuration Administration support.

cfgadm_ac(1M)

NAME	cfgadm_ac – EXX00 memory system administration
SYNOPSIS	<pre>/usr/sbin/cfgadm [-c configure] [-f] [-o disable-at-boot enable-at-boot] ac#:bank# ... /usr/sbin/cfgadm [-c unconfigure] [-o disable-at-bootp enable-at-boot] ac#:bank# ... /usr/sbin/cfgadm [-v] [-o quick normal extended, [max_errors=#]] -t ac#:bank#... /usr/sbin/cfgadm -x relocate-test ac#:bank# ... /usr/sbin/cfgadm [-l] -o disable-at-boot enable-at-boot ac#:bank# ...</pre>
DESCRIPTION	<p>The ac hardware specific library <code>/usr/platform/sun4u/lib/cfgadm/cfgadm_ac.so.1</code> provides the functionality for configuring and unconfiguring memory banks on E6X00, E5X00, E4X00 and E3X00 systems as part of the Dynamic Reconfiguration of CPU/Memory boards using <code>cfgadm_sysctrl(1M)</code>.</p> <p>Memory banks appear as attachment points in the device tree. For each CPU/Memory board, two attachment points are published, one for each bank on the board: <code>bank0</code> and <code>bank1</code>. If the bank is unpopulated, the receptacle state is <code>empty</code>. If the bank is populated, the receptacle state is <code>connected</code>. The receptacle state of a memory bank can never be disconnected. The occupant state of a connected memory bank can be configured or unconfigured. If the occupant state is configured, the memory is in use by Solaris, if unconfigured it is not.</p>
OPTIONS	<p>Refer to <code>cfgadm(1M)</code> for complete descriptions of the command options.</p> <p>The following options are supported:</p> <p><code>-c configure unconfigure</code></p> <p>Change the occupant state. The <code>configure</code> argument ensures that the memory is initialized and adds the memory to the Solaris memory pool. The <code>unconfigure</code> argument removes the memory from use by Solaris. When a CPU/Memory board is to be removed from a system, both banks of memory must be unconfigured.</p> <p><code>cfgadm</code> refuses the <code>configure</code> operation if the memory on the board is marked <code>disabled-at-boot</code> (see <code>info</code> field), unless either the <code>-f</code> (force) option or the enable at boot flag, (<code>-o enable-at-boot</code>), is given. The <code>configure</code> operation takes a short time proportional to the size of memory that must be initialized.</p> <p><code>cfgadm</code> refuses the <code>unconfigure</code> operation if there is not enough uncommitted memory in the system (<code>VM viability error</code>) or if the bank to be unconfigured has memory that can't be removed (<code>non-relocatable pages error</code>). The presence of non-relocatable pages is indicated by the word <code>permanent</code> in the <code>info</code> listing field. Removing memory from use by Solaris may take a significant time due to factors such as system load and how much paging to secondary storage is required.</p>

The `unconfigure` operation can be cancelled at any time and the memory returned to the fully configured state by interrupting the command invocation with a signal. The `unconfigure` operation self-cancels if no memory can be removed within a timeout period. The default timeout period of 60 seconds can be changed using the `-o timeout=#` option, with a value of 0 disabling the timeout.

`-f`

Force option. Use this option to override the block on configuring a memory bank marked as disabled at boot in the non-volatile `disabled-memory-list` variable. See *Platform Notes:Sun Enterprise 6x00/5x00/4x00/3x00 Systems*

`-l`

List option. This option is supported as described in `cfgadm(1M)`.

The `type` field is always `memory`.

The `info` field has the following information for empty banks:

```
slot# empty
```

The `slot#` indicates the system slot into which the CPU/Memory board is inserted. For example, if this were `slot11` the attachment point for use with `cfgadm` to manipulate the associated board would be `sysctrl0:slot11`. The `info` field has the following information for connected banks:

```
slot# sizeMb|sizeGb [(sizeMb|sizeGb used)] base 0x###
      [interleaved #-way] [disabled at boot] [permanent]
```

The size of the bank is given in Mb or Gb as appropriate. If the memory is less than completely used, the used size is reported. The physical base address is given in hexadecimal. If the memory bank is interleaved with some other bank, the interleave factor is reported. If the memory on the board is disabled at boot using the non-volatile `disabled-memory-list` variable, this is reported. If the bank has memory that cannot be removed this is reported as permanent.

`-o disable-at-boot | enable-at-boot`

These options allow the state of the non-volatile `disabled-memory-list` variable to be modified. These options can be used in conjunction with the issuing of a `-c` option or with the explicit or implied listing command, `-l`, if no command is required. Use of `-o enable-at-boot` with the `configure` command to override the block on configuring memory on a board in the disabled memory list.

`-o extended | normal | quick`

Use with the `-t` option to specify test level.

The `normal` test level ensures that each memory cell stores both a 0 and a 1, and checks that all cells are separately addressable. The `quick` test level only does the 0s and 1s test, and typically misses address line problems. The `extended` test uses patterns to test for adjacent cell interference problems. The default test level is `normal`. See `-t` option.

cfgadm_ac(1M)

- o max_errors=#
Use with the `-t` option to specify the maximum number of allowed errors. If not specified, a default of 32 is assumed.
- o timeout=#
Use with the `unconfigure` command to set the self-cancelling timeout. The default value is 60 and the unit is seconds. A value of 0 means no timeout.
- t
Test an unconfigured bank of memory. Specify the test level using the `-o quick | normal | extended` option.

cfgadm exits with a 0 (success) if the *test* was able to run on the memory bank. The result of the test is available in the condition for the attachment point.
- v
Verbose option. Use this option in combination with the `-t` option to display detailed progress and results of tests.
- x relocate-test
For all pages of memory in use on the specified memory bank, a relocation operation as used in the `unconfigure` command is attempted. The success of this operation does not guarantee that the bank can be unconfigured. Failure indicates that it probably cannot be unconfigured. This option is for test purposes only.

OPERANDS The following operand is supported:

*ac#:*bank#

The attachment points for memory banks are published by instances of the address controller (ac) driver (*ac#*). One instance of the ac driver is created for each system board, but only those instances associated with CPU/Memory boards publish the two bank attachment points, bank0 and bank1.

This form conforms to the logical `ap_id` specification given in `cfgadm(1M)`. The corresponding physical `ap_ids` are listed in the **FILES** section.

The ac driver instance numbering has no relation to the slot number for the corresponding board. The full physical attachment point identifier has the slot number incorporated into it as twice the slot number in hexadecimal directly following the `fhc@` part.

FILES /devices/fhc@*,f8800000/ac@0,1000000:bank?
attachment points

Platform Notes:Sun Enterprise 6x00/5x00/4x00/3x00 Systems

NOTES Refer to the *Sun Enterprise 6x00, 5x00, 4x00 and 3x00 Systems Dynamic Reconfiguration User's Guide* for additional details regarding dynamic reconfiguration of EXX00 system CPU/Memory boards.

cfgadm_pci(1M)

NAME	cfgadm_pci – PCI Hotplug hardware specific commands for cfgadm										
SYNOPSIS	<pre>/usr/sbin/cfgadm [-f] [-y -n] [-v] [-o hardware_options] -c function ap_id [ap_id] /usr/sbin/cfgadm [-f] [-y -n] [-v] [-o hardware_options] -x hardware_function ap_id [ap_id] /usr/sbin/cfgadm [-v] [-s listing_options] [-o hardware_options] [-l [ap_id ap_type]] /usr/sbin/cfgadm [-v] [-o hardware_options] -t ap_id [ap_id] /usr/sbin/cfgadm [-v] [-o hardware_function] -h [ap_id ap_type]</pre>										
DESCRIPTION	<p>The PCI hardware specific library <code>/usr/lib/cfgadm/pci.so.1</code> provides the support for hot plugging pci adapter cards into pci hot pluggable slots in a system that is hot plug capable, through <code>cfgadm(1M)</code>. See <code>cfgadm(1M)</code>.</p> <p>For PCI Hot Plug, each hot plug slot on a specific PCI bus is represented by an attachment point of that specific PCI bus.</p> <p>An attachment point consist of two parts: a receptacle and an occupant. The receptacle under PCI hot plug is usually referred to as the physical hot pluggable slot; and the occupant is usually referred to as the PCI adapter card that plugs into the slot.</p> <p>Attachment points are named through <code>ap_ids</code>. There are two types of <code>ap_ids</code>: logical and physical. The physical <code>ap_id</code> is based on the physical pathname, that is, <code>/devices/pci@1/hpc0_slot3</code>, whereas the logical <code>ap_id</code> is a shorter, and more user-friendly name. For PCI hot pluggable slots, the logical <code>ap_id</code> is usually the corresponding hot plug controller driver name plus the logical slot number, that is, <code>pci0:hpc0slot1</code>; pci nexus driver, with hot plug controller driver named <code>hpc</code> and slot number 1. The <code>ap_type</code> for Hot plug PCI is <code>pci</code>.</p> <p>Note that the <code>ap_type</code> is not the same as the information in the <code>Type</code> field.</p> <p>See the <i>System Administration Guide, Volume I</i> for a detailed description of the hot plug procedure.</p>										
OPTIONS	<p>The following options are supported:</p> <p><code>-c function</code></p> <p>The following <i>functions</i> are supported for PCI hot pluggable slots:</p> <table><tr><td>configure</td><td>Configure the PCI device in the slot to be used by Solaris.</td></tr><tr><td>connect</td><td>Connect the slot to PCI bus.</td></tr><tr><td>disconnect</td><td>Disconnect the slot from the PCI bus.</td></tr><tr><td>insert</td><td>Not supported.</td></tr><tr><td>remove</td><td>Not supported.</td></tr></table>	configure	Configure the PCI device in the slot to be used by Solaris.	connect	Connect the slot to PCI bus.	disconnect	Disconnect the slot from the PCI bus.	insert	Not supported.	remove	Not supported.
configure	Configure the PCI device in the slot to be used by Solaris.										
connect	Connect the slot to PCI bus.										
disconnect	Disconnect the slot from the PCI bus.										
insert	Not supported.										
remove	Not supported.										

- unconfigure Logically remove the PCI device's resources from the system.
- f
Not supported.
- h *ap_id* | *ap_type*
Print out PCI hot plug specific help message.
- l *list*
List the values of PCI Hot Plug slots.
- o *hardware_options*
No hardware specific options are currently defined.
- s *listing_options*
Same as the generic `cfgadm(1M)`.
- t *ap_id*
This command is only supported on platforms which support testing capability on the slot.
- v
Execute in verbose mode.

When `-v` is used with `-l` option the `cfgadm` command outputs information about the attachment point. For PCI Hot Plug, the `Information` field will be the slot's system label. This string will be obtained from the `slot-name` property of the slot's bus node. The information in the `Type` field is printed with or without the `-v` option. The occupant `Type` field will describe the contents of the slot. There are 2 possible values:

`NULL` The slot is empty. `NULL` should be unknown. There could be a card in the slot that is simply not configured.

subclass,board The card in the slot is either a single- function or multi-function device.

subclass is a string representing the subclass code of the device, for example, `SCSI`, `ethernet`, `pci-isa`, and so forth. If the card is a multi-functional device, `MULT` will get printed instead.

board is a string representing the board type of the device, for example, `hp` for PCI Hot Plug adapter, `hs` for Hot Swap Board, `nhs` for Non—Hot Swap cPCI Board, `bhs` for Basic Hot Swap cPCI Board, `fhs` for Full Hot Swap cPCI Board.

Most `pci` cards with more than one device on them are not actually multi-function devices, but are implemented as a `pci` bridge with arbitrary devices

behind it. In that case, the subclass displayed will be that of the `pci` bridge.

-x hardware_function

Perform hardware specific function. These hardware specific functions should not normally change the state of a receptacle or occupant.

The following *hardware_functions* are supported:

`enable_slot` | `disable_slot`

Change the state of the slot and preserve the state of slot across reboot. Preservation of state across reboot is only supported on select platforms.

`enable_slot` enables the addition of hardware to this slot for hot plugging and at boot time.

`disable_slot` disables the addition of hardware to this slot for hot plugging and at boot time. When a slot is disabled its condition is shown as unusable.

`enable_autoconfig` | `disable_autoconfig`

Change the ability to autoconfigure the occupant of the slot. Only platforms that support auto configuration support this feature.

`enable_autoconfig` enables the ability to autoconfigure the slot.

`diabile_autoconfig` disables the ability to autoconfigure the slot.

`led=[led_sub_arg],mode=[mode_sub_arg]`

Without sub-arguments, print a list of the current LED settings. With sub-arguments, set the mode of a specific LED for a slot.

Specify *led_sub_arg* as `fault`, `power`, `att`, or `active`.

Specify *mode_sub_arg* as `on`, `off` or `blink`.

Changing the state of the LED does not change the state of the receptacle or occupant. Normally, the LEDs are controlled by the hot plug controller, no user intervention is necessary. Use this command for testing purposes.

Caution: Changing the state of the LED can misrepresent the state of occupant or receptacle.

The following command prints the values of LEDs:

```
example# cfgadm -x led pci0:hpc0_slot1Ap_Id          Led
pci0:hpc0_slot1  power=on,fault=off,active=off,attn=off
```

The following command turns on the Fault LED:

```
example# cfgadm -x led=fault,mode=on pci0:hpc0_slot1
```

The following command turns off the Power LED:

```
example# cfgadm -x led=power,mode=off pci0:hpc0_slot0
```

The following command sets the *active* LED to blink to indicate the location of the slot:

```
example# cfgadm -x led=active,mode=on pci0:hpc0_slot3
```

EXAMPLES **EXAMPLE 1** Printing out the Value of Each Slot

The following command prints out the values of each slot:

```
example# cfgadm -l
Ap_Id          Type          Receptacle  Occupant    Condition
pci1:hpc0_slot0  unknown      empty       unconfigured unknown
pci1:hpc0_slot1  unknown      empty       unconfigured unknown
pci1:hpc0_slot2  unknown      empty       unconfigured unknown
pci1:hpc0_slot3  HP/SCSI     connected   configured  ok
pci1:hpc0_slot4  unknown      empty       unconfigured unknown
```

EXAMPLE 2 Replacing a Card

The following command lists all DR-capable attachment points:

```
example# cfgadm
Ap_Id          Type          Receptacle  Occupant    Condition
c0             scsi-bus     connected   configured  unknown
pci_pci0:cpci_slot1 stpcipci/fhs connected   configured  ok
pci_pci0:cpci_slot  unknown      empty       unconfigured unknown
pci_pci0:cpci_slot4 stpcipci/fhs connected   configured  ok
pci_pci0:cpci_slot5  unknown      empty       unconfigured unknown
```

The following command unconfigures and electrically disconnects the card:

```
example# cfgadm -c disconnect pci_pci0:cpci_slot4
```

The change can be verified by entering the following command:

```
example# cfgadm
Ap_Id          Type          Receptacle  Occupant    Condition
c0             scsi-bus     connected   configured  unknown
pci_pci0:cpci_slot1 stpcipci/fhs connected   configured  ok
pci_pci0:cpci_slot  unknown      empty       unconfigured unknown
pci_pci0:cpci_slot4  unknown      disconnected unconfigured unknown
pci_pci0:cpci_slot  unknown      empty       unconfigured unknown
```

Now the card can be swapped. The following command electrically connects and configures the card:

```
example# cfgadm -c configure pci_pci0:cpci_slot4
```

The change can be verified by entering the following command:

cfgadm_pci(1M)

EXAMPLE 2 Replacing a Card (Continued)

```
# cfgadm
Ap_Id          Type          Receptacle  Occupant    Condition
c0             scsi-bus     connected   configured  unknown
pci_pci0:cpci_slot1  stpcipci/fhs connected   configured  ok
pci_pci0:cpci_slot2  unknown      empty       unconfigured unknown
pci_pci0:cpci_slot4  stpcipci/fhs connected   configured  ok
pci_pci0:cpci_slot5  unknown      empty       unconfigured unknown
```

FILES /usr/lib/cfgadm/libpci.so.1 Hardware specific library for PCI hot plugging.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

System Administration Guide: Basic Administration

NAME	cfgadm_sbd – cfgadm commands for system board administration						
SYNOPSIS	<pre> cfgadm -l [-a] [-o parsable] <i>ap_id...</i> cfgadm -c <i>function</i> [-f] [-y -n] [-o unassign nopoweroff] [-v] <i>ap_id...</i> cfgadm -t [-v] <i>ap_id...</i> cfgadm -x [-f] [-v] <i>function ap_id...</i> </pre>						
DESCRIPTION	<p>The <code>cfgadm_sbd</code> plugin provides dynamic reconfiguration functionality for connecting, configuring, unconfiguring, and disconnecting class <code>sbd</code> system boards. It also enables you to connect or disconnect a system board from a running system without having to reboot the system.</p> <p>The <code>cfgadm</code> command resides in <code>/usr/sbin</code>. See <code>cfgadm(1M)</code>. The <code>cfgadm_sbd</code> plugin resides <code>/usr/platform/sun4u/lib/cfgadm</code>.</p> <p>Each board slot appears as a single attachment point in the device tree. Each component appears as a dynamic attachment point. You can view the type, state, and condition of each component, and the states and condition of each board slot by using the <code>-a</code> option.</p> <p>The <code>cfgadm</code> options perform differently depending on the platform. Additionally, the form of the attachment points is different depending on the platform. See the Platform Notes section for more information.</p>						
Component Conditions	<p>The following are the names and descriptions of the component conditions:</p> <table border="0"> <tr> <td>failed</td> <td>The component failed testing.</td> </tr> <tr> <td>ok</td> <td>The component is operational.</td> </tr> <tr> <td>unknown</td> <td>The component has not been tested.</td> </tr> </table>	failed	The component failed testing.	ok	The component is operational.	unknown	The component has not been tested.
failed	The component failed testing.						
ok	The component is operational.						
unknown	The component has not been tested.						
Component States	<p>The following is the name and description of the receptacle state for components:</p> <table border="0"> <tr> <td>connected</td> <td>The component is connected to the board slot.</td> </tr> </table> <p>The following are the names and descriptions of the occupant states for components:</p> <table border="0"> <tr> <td>configured</td> <td>The component is available for use by the Solaris operating environment.</td> </tr> <tr> <td>unconfigured</td> <td>The component is not available for use by the Solaris operating environment.</td> </tr> </table>	connected	The component is connected to the board slot.	configured	The component is available for use by the Solaris operating environment.	unconfigured	The component is not available for use by the Solaris operating environment.
connected	The component is connected to the board slot.						
configured	The component is available for use by the Solaris operating environment.						
unconfigured	The component is not available for use by the Solaris operating environment.						
Board Conditions	<p>The following are the names and descriptions of the board conditions.</p> <table border="0"> <tr> <td>failed</td> <td>The board failed testing.</td> </tr> <tr> <td>ok</td> <td>The board is operational.</td> </tr> <tr> <td>unknown</td> <td>The board has not been tested.</td> </tr> </table>	failed	The board failed testing.	ok	The board is operational.	unknown	The board has not been tested.
failed	The board failed testing.						
ok	The board is operational.						
unknown	The board has not been tested.						

Board States	<p>unusable The board slot is unusable.</p> <p>Inserting a board changes the receptacle state from empty to disconnected. Removing a board changes the receptacle state from disconnected to empty.</p> <p>Caution: Removing a board that is in the connected state or that is powered on and in the disconnected state crashes the operating system and can result in permanent damage to the system.</p> <p>The following are the names and descriptions of the receptacle states for boards:</p> <p>connected The board is powered on and connected to the system bus. You can view the components on a board only after it is in the connected state.</p> <p>disconnected The board is disconnected from the system bus. A board can be in the disconnected state without being powered off. However, a board must be powered off and in the disconnected state before you remove it from the slot.</p> <p>empty A board is not present.</p> <p>The occupant state of a disconnected board is always unconfigured. The following table contains the names and descriptions of the occupant states for boards:</p> <p>configured At least one component on the board is configured.</p> <p>unconfigured All of the components on the board are unconfigured.</p>
---------------------	--

Dynamic System Domains

Platforms based on dynamic system domains (DSDs, referred to as domains in this document) divide the slots in the chassis into electrically isolated hardware partitions (that is, DSDs). Platforms that are not based on DSDs assign all slots to the system permanently.

A slot can be empty or populated, and it can be assigned or available to any number of domains. The number of slots available to a given domain is controlled by an available component list (ACL) that is maintained on the system controller. The ACL is not the access control list provided by the Solaris operating environment.

A slot is visible to a domain only if the slot is in the domain's ACL and if it is not assigned to another domain. An unassigned slot is visible to all domains that have the slot in their ACL. After a slot has been assigned to a domain, the slot is no longer visible to any other domain.

A slot that is visible to a domain, but not assigned, must first be assigned to the domain before any other state changing commands are applied. The assign can be done explicitly using `-x assign` or implicitly as part of a connect. A slot must be unassigned from a domain before it can be used by another domain. The unassign is always explicit, either directly using `-x unassign` or as an option to disconnect using `-o unassign`.

State Change Functions

Functions that change the state of a board slot or a component on the board can be issued concurrently against any attachment point. Only one state changing operation is permitted at a given time. A Y in the Busy field in the state changing information indicates an operation is in progress.

The following list contains the functions that change the state:

- configure
- unconfigure
- connect
- disconnect

Availability Change Functions

Commands that change the availability of a board can be issued concurrently against any attachment point. Only one availability change operation is permitted at a given time. These functions also change the information string in the `cfgadm -l` output. A Y in the Busy field indicates that an operation is in progress.

The following list contains the functions that change the availability:

- assign
- unassign

Condition Change Functions

Functions that change the condition of a board slot or a component on the board can be issued concurrently against any attachment point. Only one condition change operation is permitted at a given time. These functions also change the information string in the `cfgadm -l` output. A Y in the Busy field indicates an operation is in progress.

The following list contains the functions that change the condition:

- poweron
- poweroff
- test

Unconfigure Process

This section contains a description of the unconfigure process, and illustrates the states of source and target boards at different stages during the process of moving permanent memory.

In the following code examples, the permanent memory on board 0 must be moved to another board in the domain. Thus, board 0 is the source, and board 1 is the target.

A status change operation cannot be initiated on a board while it is marked as busy. For brevity, the CPU information has been removed from the code examples.

The process is started with the following command:

```
# cfgadm -c unconfigure -y SB0::memory &
```

cfgadm_sbd(1M)

First, the memory on board 1 in the same address range as the permanent memory on board 0 must be deleted. During this phase, the source board, the target board, and the memory attachment points are marked as busy. You can display the status with the following command:

```
# cfgadm -a -s cols=ap_id:type:r_state:o_state:busy SB0 SB1
```

Ap_Id	Type	Receptacle	Occupant	Busy
SB0	CPU	connected	configured	y
SB0::memory	memory	connected	configured	y
SB1	CPU	connected	configured	y
SB1::memory	memory	connected	configured	y

After the memory has been deleted on board 1, it is marked as unconfigured. The memory on board 0 remains configured, but it is still marked as busy, as in the following example.

Ap_Id	Type	Receptacle	Occupant	Busy
SB0	CPU	connected	configured	y
SB0::memory	memory	connected	configured	y
SB1	CPU	connected	configured	y
SB1::memory	memory	connected	unconfigured	n

The memory from board 0 is then copied to board 1. After it has been copied, the occupant state for the memory is switched. The memory on board 0 becomes unconfigured, and the memory on board 1 becomes configured. At this point in the process, only board 0 remains busy, as in the following example.

Ap_Id	Type	Receptacle	Occupant	Busy
SB0	CPU	connected	configured	y
SB0::memory	memory	connected	unconfigured	n
SB1	CPU	connected	configured	n
SB1::memory	memory	connected	configured	n

After the entire process has been completed, the memory on board 0 remains unconfigured, and the attachment points are not busy, as in the following example.

Ap_Id	Type	Receptacle	Occupant	Busy
SB0	CPU	connected	configured	n
SB0::memory	memory	connected	unconfigured	n
SB1	CPU	connected	configured	n
SB1::memory	memory	connected	configured	n

The permanent memory has been moved, and the memory on board 0 has been unconfigured. At this point, you can initiate a new state changing operation on either board.

Platform-Specific Options

You can specify platform-specific options that follow the options interpreted by the system board plugin. All platform-specific options must be preceded by the

platform keyword. The following example contains the general format of a command with platform-specific options:

```
command -o sbd_options,platform=platform_options
```

OPTIONS

This man page does not include the `-v`, `-a`, `-s`, or `-h` options for the `cfgadm` command. See `cfgadm(1M)` for descriptions of those options. The following options are supported by the `cfgadm_sbd` plugin:

- `-c function` Performs a state change function. You can use the following functions:
- unconfigure**
Changes the occupant state to unconfigured. This function applies to system board slots and to all of the components on the system board.
- The `unconfigure` function removes the CPUs from the CPU list and deletes the physical memory from the system memory pool. If any device is still in use, the `cfgadm` command fails and reports the failure to the user. You can retry the command as soon as the device is no longer busy. If a CPU is in use, you must ensure that it is off line before you proceed. See `pbind(1M)`, `psradm(1M)` and `psrinfo(1M)`.
- The `unconfigure` function moves the physical memory to another system board before it deletes the memory from the board you want to unconfigure. Depending of the type of memory being moved, the command fails if it cannot find enough memory on another board or if it cannot find an appropriate physical memory range.
- For permanent memory, the operating system must be suspended (that is, quiesced) while the memory is moved and the memory controllers are reprogrammed. If the operating system must be suspended, you will be prompted to proceed with the operation. You can use the `-y` or `-n` options to always answer yes or no respectively.
- Moving memory can take several minutes to complete, depending on the amount of memory and the system load. You can monitor the progress of the operation by issuing a status command against the memory attachment point. You can also interrupt the memory operation by stopping the `cfgadm` command. The deleted memory is returned to the system memory pool.
- disconnect**
Changes the receptacle state to disconnected. This function applies only to system board slots.

If the occupant state is configured, the `disconnect` function attempts to unconfigure the occupant. It then powers off the system board. At this point, the board can be removed from the slot.

This function leaves the board in the assigned state on platforms that support dynamic system domains.

If you specify `-o nopoweroff`, the `disconnect` function leaves the board powered on. If you specify `-o unassign`, the `disconnect` function unassigns the board from the domain.

If you unassign a board from a domain, you can assign it to another domain. However, if it is assigned to another domain, it is not available to the domain from which it was unassigned.

`configure`

Changes the occupant state to configured. This function applies to system board slots and to any components on the system board.

If the receptacle state is disconnected, the `configure` function attempts to connect the receptacle. It then walks the tree of devices that is created by the `connect` function, and attaches the devices if necessary. Running this function configures all of the components on the board, except those that have already been configured.

For CPUs, the `configure` function adds the CPUs to the CPU list. For memory, the `configure` function ensures that the memory is initialized then adds the memory to the system memory pool. The CPUs and the memory are ready for use after the `configure` function has been completed successfully.

For I/O devices, you must use the `mount` and the `ifconfig` commands before the devices can be used. See `ifconfig(1M)` and `mount(1M)`.

`connect`

Changes the receptacle state to connected. This function applies only to system board slots.

If the board slot is not assigned to the domain, the `connect` function attempts to assign the slot to the domain. Next, it powers on and tests the board, then it connects the board electronically to the system bus and probes the components.

After the `connect` function is completed successfully, you can use the `-a` option to view the status of the components on the

board. The `connect` function leaves all of the components in the unconfigured state.

The assignment step applies only to platforms that support dynamic system domains.

-f Overrides software state changing constraints.

The `-f` option never overrides fundamental safety and availability constraints of the hardware and operating system.

-l Lists the state and condition of attachment points specified in the format controlled by the `-s`, `-v`, and `-a` options as specified in `cfgadm(1M)`. The `cfgadm_sbd` plugin provides specific information in the `info` field as described below. The format of this information may be altered by the `-o parsable` option.

The parsable `info` field is composed of the following:

cpu

The `cpu` type displays the following information:

`cpuid=#` Where # is a number, representing the ID of the CPU.

`speed=#` Where # is a number, representing the speed of the CPU in MHz.

`ecache=#` Where # is a number, representing the size of the ecache in MBytes.

memory

The `memory` type displays the following information, as appropriate:

`address=#` Where # is a number, representing the base physical address.

`size=#` Where # is a number, representing the size of the memory in KBytes.

`permanent=#` Where # is a number, representing the size of permanent memory in KBytes.

`unconfigurable` An operating system setting that prevents the memory from being unconfigured.

cfgadm_sbd(1M)

inter-board-interleave	The board is participating in interleaving with other boards.
source= <i>ap_id</i>	Represents the source attachment point.
target= <i>ap_id</i>	Represents the target attachment point.
deleted=#	Where # is a number, representing the amount of memory that has already been deleted in KBytes.
remaining=#	Where # is a number, representing the amount of memory to be deleted in KBytes.

io

The `io` type displays the following information:

device= <i>path</i>	Represents the physical path to the I/O component.
referenced	The I/O component is referenced.

board

The `board` type displays the following boolean names. If they are not present, then the opposite applies.

assigned	The board is assigned to the domain.
powered-on	The board is powered on.

The same items appear in the `info` field in a more readable format if the `-o parsable` option is not specified.

-o parsable

Returns the information in the `info` field as a boolean *name* or a set of `name=value` pairs, separated by a space character.

The `-o parsable` option can be used in conjunction with the `-s` option. See the `cfgadm(1M)` man page for more information about the `-s` option.

-t

Tests the board.

Before a board can be connected, it must pass the appropriate level of testing.

Use of this option always attempts to test the board, even if it has already passed the appropriate level of testing. Testing is also performed when a `-c connect` state change function is issued, in which case the test step can be skipped if the board already shows an appropriate level of testing. Thus the `-t` option can be used to explicitly request that the board be tested.

-x function

Performs an sbd-class function. You can use the following functions:

assign

Assigns a board to a domain.

The receptacle state must be disconnected or empty. The board must also be listed in the domain available component list. See Dynamic System Domains.

unassign

Unassigns a board from a domain.

The receptacle state must be disconnected or empty. The board must also be listed in the domain available component list. See Dynamic System Domains.

poweron

Powers the system board on.

The receptacle state must be disconnected.

poweroff

Powers the system board off.

The receptacle state must be disconnected.

OPERANDS The following operands are supported:

Receptacle *ap_id* For the Sun Fire 15000, the receptacle attachment point ID takes the form `SBX` or `IOX`, where `X` equals the slot number.

The exact format depends on the platform and typically corresponds to the physical labelling on the machine. See the platform specific information in the NOTES section.

Component *ap_id* The component attachment point ID takes the form `component_typeX`, where `component_type` equals one of the component types described in "Component Types" and `X` equals the component number. The component number is a board-relative unit number.

The above convention does not apply to memory components. Any DR action on a memory attachment point affects all of the memory on the system board.

EXAMPLES

The following examples show user input and system output on a Sun Fire 15000 system. User input — specifically references to attachment points — and system output may differ on other Sun Fire systems, such as the 6800 and 4810 models. Refer to the Platform Notes for specific information about using the `cfgadm_sbd` plugin on non-15000 models.

EXAMPLE 1 Listing All of the System Board

```
# cfgadm -a -s "select=class(sbd) "
```

Ap_Id	Type	Receptacle	Occupant	Condition
SB0	CPU	connected	configured	ok
SB0::cpu0	cpu	connected	configured	ok
SB0::memory	memory	connected	configured	ok
IO1	HPCI	connected	configured	ok
IO1::pci0	io	connected	configured	ok
IO1::pci1	io	connected	configured	ok
SB2	CPU	disconnected	unconfigured	failed
SB3	CPU	disconnected	unconfigured	unusable
SB4	unknown	empty	unconfigured	unknown

This example demonstrates the mapping of the following conditions:

- The board in Slot 2 failed testing.
- Slot 3 is unusable; thus, you cannot hot plug a board into that slot.

EXAMPLE 2 Listing All of the CPUs on the System Board

```
# cfgadm -a -s "select=class(sbd):type(cpu) "
```

Ap_Id	Type	Receptacle	Occupant	Condition
SB0::cpu0	cpu	connected	configured	ok
SB0::cpu1	cpu	connected	configured	ok
SB0::cpu2	cpu	connected	configured	ok
SB0::cpu3	cpu	connected	configured	ok

EXAMPLE 3 Displaying the CPU Information Field

```
# cfgadm -l -s noheadings,cols=info SB0::cpu0
```

cpuid 16, speed 400 MHz, ecache 8 Mbytes

EXAMPLE 4 Displaying the CPU Information Field in Parsable Format

```
# cfgadm -l -s noheadings,cols=info -o parsable SB0::cpu0
```

cpuid=16 speed=400 ecache=8

EXAMPLE 5 Displaying the Devices on an I/O Board

```
# cfgadm -a -s noheadings,cols=ap_id:info -o parsable IO1

IO1          powered-on assigned
IO1::pci0 device=/devices/saf@0/pci@0,2000 referenced
IO1::pci1 device=/devices/saf@0/pci@1,2000 referenced
```

EXAMPLE 6 Monitoring an Unconfigure Operation

In the following example, the memory sizes are displayed in Kbytes.

```
# cfgadm -c unconfigure -y SB0::memory &
# cfgadm -l -s noheadings,cols=info -o parsable SB0::memory SB1::memory

address=0x0 size=2097152 permanent=752592 target=SB1::memory
      deleted=1273680 remaining=823472
address=0x1000000 size=2097152 source=SB0::memory
```

EXAMPLE 7 Assigning a Slot to a Domain

```
# cfgadm -x assign SB2
```

EXAMPLE 8 Unassigning a Slot from a Domain

```
# cfgadm -x unassign SB3
```

ATTRIBUTES See attributes(5) for a description of the following attribute:

NOTES This section contains information on how to monitor the progress of a memory delete operation. It also contains platform specific information.

Memory Delete Monitoring The following shell script can be used to monitor the progress of a memory delete operation.

```
# cfgadm -c unconfigure -y SB0::memory &
# watch_memdel SB0

#!/bin/sh
# This is the watch_memdel script.

if [ -z "$1" ]; then
    printf "usage:  %s board_id\n" `basename $0`
    exit 1
```

cfgadm_sbd(1M)

```
fi
board_id=$1
cfgadm_info='cfgadm -s noheadings,cols=info -o parsable'
eval `$cfgadm_info $board_id::memory`
if [ -z "$remaining" ]; then
    echo no memory delete in progress involving $board_id
    exit 0
fi
echo deleting target $target
while true
do
    eval `$cfgadm_info $board_id::memory`
    if [ -n "$remaining" -a "$remaining" -ne 0 ]
    then
        echo $deleted KBytes deleted, $remaining KBytes remaining
        remaining=
    else
        echo memory delete is done
        exit 0
    fi
    sleep 1
done
exit 0
```

Sun Enterprise 10000 Platform Notes

The following syntax is used to refer to Platform Notes attachment points on the Sun Enterprise 10000 system:

board : : *component*

where *board* refers to the system board; and *component* refers to the individual component. System boards can range from SB0 (zero) to SB15. A maximum of sixteen system boards are available.

The DR 3.0 model running on a Sun Enterprise 10000 domain supports a limited subset of the functionality provided by the `cfgadm_sbd` plugin. The only supported operation is to view the status of attachment points in the domain. This corresponds to the `-l` option and all of its associated options.

Attempting to perform any other operation from the domain will result in an error that states that the operation is not supported. All operations to add or remove a system board must be initiated from the System Service Processor.

Sun Fire 15000 Platform Notes

The following syntax is used to refer to attachment points on the Sun Fire 15000 system:

board : : *component*

where *board* refers to the system board or I/O board; and *component* refers to the individual component.

Depending on the system's configuration, system boards can range from SB0 (zero) through SB17, and I/O boards can range from IO0 (IO zero) through IO17. (A maximum of eighteen system and I/O boards are available).

The `-t` and `-x` options behave differently on the Sun Fire 15000 platform. The following list describes their behavior:

`-t` The system controller uses a CPU to test system boards by running `LPOST`, sequenced by the `hpost` command. To test I/O boards, the driver starts the testing in response to the `-t` option, and the test runs automatically without user intervention. The driver unconfigures a CPU and a stretch of contiguous physical memory. Then, it sends a command to the system controller to test the board. The system controller uses the CPU and memory to test the I/O board from inside of a transaction/error cage.

`-x assign | unassign` In the Sun Fire 15000 system administration model, the platform administrator controls the platform hardware through the use of an available component list for each domain. This information is maintained on the system controller. Only the platform administrator can modify the available component list for a domain.

The domain administrator is only allowed to assign or unassign a board if it is in the available component list for that domain. The platform administrator does not have this restriction, and can assign or unassign a board even if it is not in the available component list for a domain.

**Sun Fire 15000
Component Types**

The following are the names and descriptions of the component types:

<code>cpu</code>	CPU
<code>io</code>	I/O device
<code>memory</code>	Memory

Note: An operation on a memory component affects all of the memory components on the board.

**Sun Fire 6800,
4810, 4800 and 3800
Platform Notes**

References to attachment points are slightly different on Sun Fire 6800, 4810, 4800, and 3800 systems than on the Sun Fire 15000 system. The following syntax is used to refer to attachment points on Sun Fire systems other than the Sun Fire 15000:

`N# .board : .component`

cfgadm_sbd(1M)

where **N#** refers to the node; *board* refers to the system board or I/O board; and *component* refers to the individual component.

Depending on the system's configuration, system boards can range from SB0 through SB5, and I/O boards can range from IB6 through IB9. (A maximum of six system and four I/O boards are available).

**Sun Fire 6800,
4810, 4800 and 3800
Component Types**

The following are the names and descriptions of the component types:

cpu	CPU
pci	I/O device
memory	Memory

Note: An operation on a memory component affects all of the memory components on the board.

NAME | `cfgadm_scsi` – SCSI hardware specific commands for `cfgadm`

SYNOPSIS | `/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_option] -c function ap_id...`

| `/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_option] -x hardware_function ap_id...`

| `/usr/sbin/cfgadm [-v] [-a] [-s listing_option] [-o hardware_option] [-l [ap_id | ap_type ...]]`

| `/usr/sbin/cfgadm [-v] [-o hardware_option] -t ap_id...`

| `/usr/sbin/cfgadm [-v] [-o hardware_option] -h [ap_id...]`

DESCRIPTION | The SCSI hardware specific library `/usr/lib/cfgadm/scsi.so.1` provides the functionality for SCSI hot-plugging through the `cfgadm(1M)` command. `cfgadm` operates on attachment points, which are locations in the system where hardware resources can be dynamically reconfigured. Refer to `cfgadm(1M)` for information regarding attachment points.

For SCSI hot-plugging, each SCSI controller is represented by an attachment point in the device tree. In addition, each SCSI device is represented by a dynamic attachment point. Attachment points are named through `ap_ids`. Two types of `ap_ids` are defined: logical and physical. The physical `ap_id` is based on the physical pathname, whereas the logical `ap_id` is a shorter more user-friendly name. For SCSI controllers, the logical `ap_id` is usually the corresponding disk controller number. For example, a typical logical `ap_id` would be `c0`.

SCSI devices are named relative to the controller `ap_id`. Thus if a disk device is attached to controller `c0`, its `ap_id` can be:

```
c0::dsk/c0t0d0
```

where `dsk/c0t0d0` identifies the specific device. In general, the device identifier is derived from the corresponding logical link for the device in `/dev`. For example, a SCSI tape drive logical `ap_id` could be `c0::rmt/0`. Here `c0` is the logical `ap_id` for the SCSI controller and `rmt/0` is derived from the logical link for the tape drive in `/dev/rmt`. If an identifier can not be derived from the link in `/dev`, a unique identifier will be assigned to it. For example, if the tape device has no link in `/dev`, it can be assigned an `ap_id` of the form `c0::st3` where `st3` is a unique internally generated identifier.

A simple listing of attachment points in the system will include attachment points at SCSI controllers but not SCSI devices. Use the `-a` flag to the list option (`-l`) to list SCSI devices as well. For example:

```
# cfgadm -l
Ap_Id           Type           Receptacle      Occupant        Condition
c0              scsi-bus      connected       configured      unknown
sysctrl10:slot0  cpu/mem       connected       configured      ok
sysctrl10:slot1  sbus-upa      connected       configured      ok
```

cfgadm_scsi(1M)

To list SCSI devices in addition to SCSI controllers:

```
# cfgadm -al

Ap_Id          Type          Receptacle  Occupant    Condition
c0             scsi-bus     connected   configured  unknown
c0::dsk/c0t14d0  disk        connected   configured  unknown
c0::dsk/c0t11d0  disk        connected   configured  unknown
c0::dsk/c0t8d0   disk        connected   configured  unknown
c0::dsk/c0t0d0   disk        connected   configured  unknown
c0::rmt/0        tape        connected   configured  unknown
sysctrl0:slot0  cpu/mem     connected   configured  ok
sysctrl0:slot1  sbus-upa    connected   configured  ok
```

Refer to `cfgadm(1M)` for more information regarding listing attachment points. The receptacle and occupant state for attachment points at the SCSI controller have the following meanings:

empty

not applicable

disconnected

bus quiesced (I/O activity on bus is suspended)

connected

bus active

configured

one or more devices on the bus is configured

unconfigured

no device on the bus is configured

The corresponding states for individual SCSI devices are:

empty

not applicable

disconnected

bus to which the device is attached is quiesced

connected

bus to which device is attached is active

configured

device is configured

unconfigured

device is not configured

OPTIONS

`cfgadm` defines several types of operations besides listing (-l). These operations include testing, (-t), invoking configuration state changes, (-c), invoking hardware specific functions (-x), and obtaining configuration administration help messages (-h).

-c function The following generic commands are defined for the SCSI hardware specific library:

For SCSI controller attachment points, the following configuration state change operations are supported:

connect	Unquiesce the SCSI bus.
disconnect	Quiesce the bus (suspend I/O activity on bus).
	Incorrect use of this command can cause the system to hang. See NOTES.
configure	Configure new devices on SCSI bus.
unconfigure	Unconfigure all devices connected to bus.

The following generic commands are defined for SCSI devices:

configure	configure a specific device
unconfigure	unconfigure a specific device

-f When used with the `disconnect` command, forces a quiesce of the SCSI bus, if supported by hardware.

Incorrect use of this command can cause the system to hang. See NOTES.

-h ap_id SCSI specific help can be obtained by using the help option with any SCSI attachment point.

-o hardware_option No hardware specific options are currently defined.

-s listing_option Attachment points of class `scsi` can be listed by using the `select` sub-option. Refer to the `cfgadm(1M)` man page for additional information.

-t ap_id No test commands are available at present.

-x hardware_function Some of the following commands can only be used with SCSI controllers and some only with SCSI devices.

In the following, *controller_ap_id* refers to an `ap_id` for a SCSI controller, for example, `c0`. *device_ap_id* refers to an `ap_id` for a SCSI device, for example: `c0::disk/c0dt3d0`.

The following hardware specific functions are defined:

`insert_device controller_ap_id`

Add a new device to the SCSI controller, `controller_ap_id`.

This command is intended for interactive use only.

`remove_device device_ap_id`

Remove device `device_ap_id`.

This command is intended for interactive use only.

`replace_device device_ap_id`

Remove device `device_ap_id` and replace it with another device of the same kind.

This command is intended for interactive use only.

`reset_device device_ap_id`

Reset `device_ap_id`.

`reset_bus controller_ap_id`

Reset bus `controller_ap_id` without resetting any devices attached to the bus.

`reset_all controller_ap_id`

Reset bus `controller_ap_id` and all devices on the bus.

EXAMPLES

EXAMPLE 1 Configuring a Disk

The following command configures a disk attached to controller `c0`:

```
# cfgadm -c configure c0::dsk/c0t3d0
```

EXAMPLE 2 Unconfiguring a Disk

The following command unconfigures a disk attached to controller `c0`:

```
# cfgadm -c unconfigure c0::dsk/c0t3d0
```

EXAMPLE 3 Adding a New Device

The following command adds a new device to controller `c0`:

```
# cfgadm -x insert_device c0
```

The system responds with the following:

```
Adding device to SCSI HBA: /devices/sbus@1f,0/SUNW,fas@e,8800000
This operation will suspend activity on SCSI bus c0
Continue (yes/no)?
```

Enter:

EXAMPLE 3 Adding a New Device (Continued)

y

The system responds with the following:

```
SCSI bus quiesced successfully.
It is now safe to proceed with hotplug operation.
Enter y if operation is complete or n to abort (yes/no)?
```

Enter:

y

EXAMPLE 4 Replacing a Device

The following command replaces a device attached to controller c0:

```
# cfgadm -x replace_device c0::dsk/c0t3d0
```

The system responds with the following:

```
Replacing SCSI device: /devices/sbus@1f,0/SUNW,fas@e,8800000/sd@3,0
This operation will suspend activity on SCSI bus: c0
Continue (yes/no)?
```

Enter:

y

The system responds with the following:

```
SCSI bus quiesced successfully.
It is now safe to proceed with hotplug operation.
Enter y if operation is complete or n to abort (yes/no)?
```

Enter:

y

EXAMPLE 5 Encountering a Mounted File System While Unconfiguring a Disk

The following command illustrates encountering a mounted file system while unconfiguring a disk:

```
# cfgadm -c unconfigure c1::dsk/c1t0d0
```

The system responds with the following:

```
cfgadm: Component system is busy, try again: failed to offline:
/devices/pci@1f,4000/scsi@3,1/sd@1,0
      Resource          Information
-----
/dev/dsk/c1t0d0s0    mounted filesystem "/mnt"
```

cfgadm_scsi(1M)

FILES /usr/lib/cfgadm/scsi.so.1 hardware specific library for generic SCSI hot-plugging

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs1 (32-bit)
	SUNWcs1x (64-bit)

SEE ALSO cfgadm(1M), luxadm(1M), config_admin(3CFGADM), libcfgadm(3LIB), attributes(5)

NOTES The disconnect (quiesce) operation is not supported on controllers which control disks containing critical partitions such as root (/), /usr, swap, or /var. The disconnect operation should not be attempted on such controllers. Incorrect usage can result in a system hang and require a reboot.

Hotplugging operations are not supported by all SCSI controllers.

WARNINGS The connectors on some SCSI devices do not confirm to SCSI hotplug specifications. Performing hotplug operations on such devices can cause damage to the hardware on the SCSI bus. Refer to your hardware manual for additional information.

NAME	cfgadm_sysctrl – EXX00 system board administration
SYNOPSIS	<pre> /usr/sbin/cfgadm -c <i>function</i> [-f] [-o disable-at-boot enable-at-boot] [-n -y] sysctrl0:slot# ... /usr/sbin/cfgadm -x quiesce-test sysctrl0:slot# /usr/sbin/cfgadm -x insert-test remove-test sysctrl0:slot# ... /usr/sbin/cfgadm -x set-condition-test=# sysctrl0:slot# ... /usr/sbin/cfgadm [-l] -o disable-at-boot enable-at-boot sysctrl0:slot# ... </pre>
DESCRIPTION	<p>The <code>sysctrl</code> hardware specific library <code>/usr/platform/sun4u/lib/cfgadm/sysctrl.so.1</code> provides dynamic reconfiguration functionality for configuring and disconnecting system boards on E6X00, E5X00, E4X00, and E3X00 systems. You can insert both I/O and CPU boards into a slot on a running system that is configured for Solaris without rebooting. You can also disconnect and remove both types of boards from a running system without rebooting.</p> <p>System slots appear as attachment points in the device tree, one attachment point for each actual slot in the system chassis. If a board is not in a slot, the receptacle state is empty. If a board is powered-off and ready to remove, the receptacle state is disconnected. If a board is powered-on and is connected to the system bus, the receptacle state is connected.</p> <p>The occupant state is unconfigured when the receptacle state is empty or disconnected. The occupant state is either unconfigured or configured when the receptacle state is connected.</p> <p>In the configured state the devices on a board are available for use by Solaris. In the unconfigured state, the devices on the board are not.</p> <p>Inserting a board changes the receptacle state from empty to disconnected. Removing a board changes the receptacle state from disconnected to empty. Removing a board that is in the connected state crashes the operating system and can result in permanent damage to the system.</p>
OPTIONS	<p>Refer to <code>cfgadm(1M)</code> for a more complete description options.</p> <p>The following options are supported:</p> <ul style="list-style-type: none"> -c <i>function</i> Perform the state change function. Specify <i>function</i> as connect, disconnect, configure or unconfigure. configure Change the occupant state to configure.

cfgadm_sysctrl(1M)

If the receptacle state is `disconnected`, the `configure` function first attempts to connect the receptacle. The `configure` function walks the OBP device tree created as part of the `connect` function and creates the Solaris device tree nodes, attaching devices as required. For CPU/Memory boards, `configure` adds CPUs to the CPU list in the `powered-off` state. These are visible to the `psrinfo(1M)` and `psradm(1M)` commands. Two memory attachment points are published for CPU/memory boards. Use `mount(1M)` and `difconfig(1M)` to use I/O devices on the new board. To use CPUs, use `psradm -n` to on-line the new processors. Use `cfgadm_ac(1M)` to test and configure the memory banks.

connect

Change the receptacle state to `connected`.

Changing the receptacle state requires that the system bus be frozen while the bus signals are connected and the board tested. The bus is frozen by running a `quiesce` operation which stops all process activity and suspends all drivers. Because the `quiesce` operation and the subsequent resume can be time consuming, and are not supported by all drivers, the `-x quiesce-test` is provided. While the system bus is frozen, the board being connected is tested by firmware. This operation takes a short time for I/O boards and a significant time for CPU/Memory boards due to CPU external cache testing. This does not provide memory testing. The user is prompted for confirmation before proceeding with the `quiesce`. Use the `-y` or `-n` option to override the prompt. The `connect` operation is refused if the board is marked as `disabled-at-boot`, unless either the force flag, `-f`, or the enable at boot flag, `-o enable-at-boot`, is given. See `-l`.

disconnect

Change the receptacle state to `disconnected`.

If the occupant state is `configure`, the `disconnect` function first attempts to unconfigure the occupant. The `disconnect` operation does not require a `quiesce` operation and operates quickly. The board is powered-off ready for removal.

unconfigure

Change the occupant state to `unconfigured`.

Devices on the board are made invisible to Solaris during this process. The I/O devices on an I/O board are removed from the Solaris device tree. Any device that is still in use stops the `unconfigure` process and be reported as in use. The `unconfigure` operation must be retried after the device is made non-busy. For CPU/Memory boards, the memory must have been changed to the `unconfigured` state prior to issuing the board `unconfigure` operation. The CPUs on the board are off-lined, powered off and removed from the Solaris CPU list. CPUs that have processes bound to them cannot be off-lined. See `psradm(1M)`, `psrinfo(1M)`, `pbind(1M)`, and `andp_online(2)` for more information on off-lining CPUs.

- f
Force a block on connecting a board marked as `disabled-at-boot` in the non-volatile `disabled-board-list` variable. See *Platform Notes:Sun Enterprise 6x00/5x00/4x00/3x00 Systems*
- l
List options. Supported as described in `cfgadm(1M)cfgadm(1M)`.

The *type* field can be one of `cpu/mem`, `mem`, `dual-sbus`, `sbus-upa`, `dual-pci`, `soc+sbus`, `soc+upa`, `disk` or `unknown`.

The hardware-specific info field is set as follows: `[disabled at boot]`
`[non-detachable] [100 MHz capable]`

For `sbus-upa` and `soc+upa` type boards, the following additional information appears first: `[single buffered ffb|double buffered ffb|no ffb installed]` For disk type boards, the following additional information appears first: `{target: # | no disk} {target: # | no disk}`
- o `disable-at-boot` | `enable-at-boot`
Modify the state of the non-volatile `disabled-board-list` variable. Use this the `-o` option in conjunction with the `-c function` or `-l` option.

Use `-o enable-at-boot` with the `-c connect` to override a block on connecting a `disabled-at-boot` board.
- x `insert-test` | `remove-test`
Perform a test.

Specify `remove-test` to change the driver state for the specified slot from `disconnected` to `empty` without the need for physically removing the board during automated test sequences.

Specify `insert-test` to change the driver state of a slot made to appear empty using the `remove-test` command to the `disconnected` state as if it had been inserted.
- x `quiesce-test sysctrl0:slot1`
Perform a test.

Allows the `quiesce` operation required for board connect operations to be exercised. The execution of this test confirms that, with the current software and hardware configuration, it is possible to quiesce the system. If a device or process cannot be quiesced, its name is printed in an error message. Any valid board attachment point can be used with this command, but since all systems have a `slot1` the given form is recommended.
- x `set-condition-test=#`
Perform a test.

cfgadm_sysctrl(1M)

Allows the the condition of a system board attachment point to be set for testing the policy logic for state change commands. The new setting is given as a number indicating one of the following condition values:

- 0 unknown
- 1 ok
- 2 failing
- 3 failed
- 4 unusable

OPERANDS The following operand is supported:

`sysctrl0:slot#` The attachment points for boards on EXX00 systems are published by instance 0 of the `sysctrl` driver (`sysctrl0`). The names of the attachment points are numbered from `slot0` through `slot15`. Specify # as a number between 0 and 15, indicating the slot number. This form conforms to the logical `ap_id` specification given in `cfgadm(1M)`. The corresponding physical `ap_ids` are listed in the **FILES** section.

NAME | `cfgadm_usb` – USB hardware-specific commands for `cfgadm`

SYNOPSIS | `/usr/sbin/cfgadm [-f] [-y | -n] [-v] -c function ap_id...`
`/usr/sbin/cfgadm -f [-y | -n] [-v] [-o hardware_option] -x`
`hardware_function ap_id...`
`/usr/sbin/cfgadm -v [-a] [-s listing_option] [-l [ap_id | ap_type...]]`
`/usr/sbin/cfgadm -v -h [ap_id...]`

DESCRIPTION | The Universal Serial Bus (USB) hardware-specific library `/usr/lib/cfgadm/usb.so.1` provides the functionality for administering USB devices through the `cfgadm(1M)`. The `cfgadm` command operates on attachment points. For details regarding attachment points, refer to `cfgadm(1M)`.

For USB administration, the only attachment points supported are the ports of hubs attached to the USB bus.

Attachment points are named through attachment point IDs (*ap_ids*). The USB bus is hierarchical, so the *ap_ids* are as well. USB hubs have ports, numbered from 1 to *n*. All USB *ap_ids* consist of a string of the following form,

```
usbN/A[.B[.C[...]]]
```

where,

- N* is the *N*th USB host controller on the system,
- A* is port #*A* on the root (top) hub.
- B* is port #*B* of the hub plugged into port #*A* of the hub above it.
- C* is port #*C* of the hub plugged into port #*B* of the hub above it and so forth.

For example, the first port on the root hub of USB controller 0 (the only controller), has a logical *ap_id*:

```
usb0/1
```

Similarly, the second port on the first external hub plugged into the first port on the root hub of the first USB controller has a logical *ap_id*:

```
usb0/1.2
```

For example, if the *ap_id* is `usb0/1.4.3.4`, it represents port 4 of the hub plugged into port 3 of the hub plugged into port 4 of the hub plugged into port 1 of the root hub of the first USB bus controller on the system.

The following listing of USB attachment points in the system includes all attachment points for USB ports, even if the port is empty (no device plugged in):

```
# cfgadm -l
Ap_Id                Type          Receptacle  Occupant    Condition
usb0/1               USB-hub      connected   configured  ok
```

cfgadm_usb(1M)

usb0/2	unknown	empty	unconfigured	ok
usb0/1.1	USB-storage	connected	configured	ok
usb0/1.2	unknown	empty	unconfigured	ok
usb0/1.3	unknown	empty	unconfigured	ok
usb0/1.4	USB-composit	connected	configured	ok

The receptacle states for attachment points at the USB port have the following meanings:

connected	USB port is powered on and enabled. A USB device is plugged in to the port. The device is logically connected to the USB bus.
disconnected	USB port is powered on and enabled. A USB device is plugged in to the port. The device has been logically disconnected from the USB bus (using the <code>cfgadm -c disconnect</code> command).
empty	USB port is powered on, but no device is plugged in to it.

The occupant states for attachment points at the USB port have the following meanings:

configured	USB device at the USB port is configured and usable by Solaris.
unconfigured	A USB device at the USB port was explicitly off-lined using <code>cfgadm -c unconfigure</code> , or was not successfully configured for use with Solaris, for example, having no driver or a device problem.

The attachment point conditions are:

ok	Normal state - ready for use.
failing	Not used.
failed	Not used.
unusable	The user has physically removed a device while an application had the device open (there may be outstanding I/O). Users need to reinsert the same physical device and close the application properly before removing the device again. The port cannot configure other inserted devices until this is done.

If the original device cannot be reinserted into the port, see the *System Administration Guide, Volume 1* for instructions for clearing this attachment point condition.

unknown	Not used.
---------	-----------

A USB device can be hotplugged or hotunplugged at any time, and the system detects the event and take the appropriate action.

It is not necessary to transition a receptacle to the `disconnected` state before removing it from the USB. However, it is not recommended to hot-remove devices currently in use (such as removable disks currently opened by an application, for instance, volume manager). See `vold(1M)`.

OPTIONS

cfgadm defines several types of operations. These operations include invoking configuration state changes (`-c`), invoking hardware-specific functions (`-x`), and obtaining configuration administration help messages (`-h`).

If any of these operations fail, the device and attachment point may not be in the expected state. Use the `cfgadm -l` command to display the device's current status.

All other options have the same meaning as defined in the `cfgadm(1M)` man page.

The following options are supported:

-c function

The following generic commands are defined for the USB hardware specific library. The following configuration state change operations are supported:

configure

If there is a USB device plugged into the port, attempt to configure it and set everything up so that it is usable by Solaris. This command does an implied connect (reverse of `disconnect`) if necessary. This command accomplishes nothing if the device at that port is already configured, so an error message is returned. After successful execution of this command the device is ready for use under Solaris.

disconnect

Perform an `unconfigure` on the `ap_id` (if it is not already unconfigured), and then transition the receptacle to the `disconnected` state. This command does an implied `unconfigure` if necessary. Note a device will still be plugged into the port. Issuing a `cfgadm -c configure` (or physically hotplugging the device) will bring the device back to the `connected` receptacle state, and to the `configured` occupant state (assuming a driver can be found, and there are no problems enumerating and configuring the device).

unconfigure

Make the device plugged into the port unusable by Solaris (offline it). If successful, `cfgadm` will now report this `ap_id`'s occupant state as `unconfigured`. Issuing a `configure` to the `ap_id` (if successful) will bring it back to the `configured` (online) condition, as will physically hotplugging the device on the port.

-f

Not supported.

-h ap_id

USB specific help may be obtained by using the help option with any USB attachment point.

-l [v]

The `-l` option works as described in `cfgadm(1M)`. When paired with the `-v` option, the Information field contains the following USB-specific information:

- Mfg: manufacturer string (`iManufacturer`)

cfgadm_usb(1M)

- **Product**: product string (*iProduct*)
- **NConfigs**: total number of configurations the device supports (*bNumConfigurations*). (in decimal)
- **Config**: current configuration setting in decimal (configuration index, not configuration value).
- The configuration string descriptor for the current configuration (*iConfiguration*)

See the Universal Serial Bus specification for a description of these fields.

-o *hardware_options*

Attachment points of class USB may be listed by using the select sub-option. See `cfgadm(1M)`.

-s *listing_options*

Attachment points of class USB may be listed by using the select sub-option. See `cfgadm(1M)`.

-x *hardware_function*

The following hardware-specific functions are defined:

`usb_config -o config=n` This command requires the mandatory `config` value to be specified using the `-o` option.

Set the USB configuration of a multi-configuration USB device at *ap_id* to configuration index *-n*. The device will be set to this configuration henceforth. This setting shall persist across reboots, hot-removes and unconfigure/configure of the device.

Valid values of *n* range from 0 to (`Nconfigs - 1`). The device is reset (by a `disconnect` followed by a `configure`). The `configure` causes the device to be configured to the new configuration setting.

If any of these steps fail, the configuration file and the device are restored to their previous state and an error message is issued.

`usb_reset`

Software reset (re-enumeration) of the device. This is the equivalent of removing the device and inserting it back again. The port on the hub will be power cycled if the hub supports power cycling of individual ports.

If a hub is the device connected to the port, this function has the effect of resetting that hub and any devices down the chain of devices connected to it.

If any of these steps fail, the device is restored to its previous state and an error message is issued.

EXAMPLES | **EXAMPLE 1** Listing the Status of All USB Devices

The following command lists the status of all USB devices on the system:

```
# cfgadm
Ap_Id          Type          Receptacle  Occupant    Condition
usb0/1         USB-hub       connected   configured  ok
usb0/2         unknown       empty        unconfigured ok
usb0/1.1       USB-storage   connected   configured  ok
usb0/1.2       unknown       empty        unconfigured ok
usb0/1.3       unknown       empty        unconfigured ok
usb0/1.4       USB-composit  connected   configured  ok
```

Note the the device at `ap_id usb0/1.4` is a *composite* device. `cfgadm_usb` treats it as a unit, it cannot currently control individual interaces of device.

EXAMPLE 2 Listing the Status of a Port with No Device Plugged In

The following command lists the status of a port with no device plugged in:

```
# cfgadm -l usb0/1.3
Ap_Id          Type          Receptacle  Occupant    Condition
usb0/1.3       unknown       empty        unconfigured ok
```

EXAMPLE 3 Listing the Status of Same Port with a Device Plugged In

The following command lists the status of the same port after physically plugging in a device, which configures without problems:

```
# cfgadm -l usb0/1.3
Ap_Id          Type          Receptacle  Occupant    Condition
usb0/1.3       USB-hub       connected   configured  ok
```

EXAMPLE 4 Unconfiguring an Existing USB Device

The following command unconfigures the USB device attached to `usb0/1.3`, then displays the status of the `ap_id`:

```
# cfgadm -c unconfigure usb0/1.3
Unconfigure the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation will suspend activity on the USB device
Continue (yes/no)?

Enter:

Y

# cfgadm -l usb0/1.3
Ap_Id          Type          Receptacle  Occupant    Condition
usb0/1.3       unknown       connected   unconfigured ok
```

cfgadm_usb(1M)

EXAMPLE 5 Unconfiguring and Logically Disconnecting an Existing USB Device

The following command unconfigures and logically disconnects a USB device attached to usb0/1.3:

```
# cfgadm -c disconnect usb0/1.3
Disconnect the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation will suspend activity on the USB device
Continue (yes/no)?
```

Enter:

Y

```
# cfgadm -l usb0/1.3
Ap_Id      Type      Receptacle  Occupant    Condition
usb0/1.3   unknown   disconnected  unconfigured ok
```

A disconnect implies `cfgadm` does an unconfigure first. The receptacle status now shows `disconnected`, even though the device is still physically connected. In this case, a physical hotplug or using the `cfgadm -c configure` on the `ap_id` brings it back on-line.

EXAMPLE 6 Configuring a Previously Unconfigured USB Device

The following command configures a USB device that was previously attached to usb0/1.3

```
# cfgadm -yc configure usb0/1.3
# cfgadm -l usb0/1.3
Ap_Id      Type      Receptacle  Occupant    Condition
usb0/1.3   unknown   connected   configured  ok
```

EXAMPLE 7 Resetting a USB Device

The following command resets an USB device:

```
# cfgadm -x usb_reset usb0/1.3
Reset the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation will suspend activity on the USB device
Continue (yes/no)?
```

Enter:

Y

EXAMPLE 8 Displaying Detailed Information About a USB Device

The following command displays detailed information about a USB device. This device shows the following USB-specific info in the 'Information' field:

- Manufacturer string: Iomega
- Product string: USB Zip 250

EXAMPLE 8 Displaying Detailed Information About a USB Device (Continued)

- Number of configurations supported:
- Configuration currently active: 0
- Configuration string descriptor for configuration 0: Default

```
# cfgadm -lv usb0/1.5
Ap_Id          Receptacle  Occupant    Condition  Information
When          Type        Busy        Phys_Id
usb0/1.5      connected   configured  ok         Mfg:"Io
mega" Product:"USB Zip 250" NConfigs:1 Config:0 : Default
:1.5

# cfgadm -l -s "cols=ap_id:info" usb0/1.5
Ap_Id          Information
usb0/1.5      Mfg:"Iomega" Product:"USB Zip 250"
NConfigs:1 Config:0 : Default
```

EXAMPLE 9 Displaying Detailed Information About All USB Devices on the System

The following command displays detailed information about all USB devices on the system:

```
# cfgadm -l -s "select=class(usb),cols=ap_id:info"
Ap_Id          Information
usb0/1         Mfg:<undefined> Product:<undefined>
NConfigs:1 Config:0 <no cfg str descr>
usb0/2
usb0/1.1       Mfg:<undefined> Product:<undefined>
NConfigs:1 Config:0 <no cfg str descr>
usb0/1.2
usb0/1.3
usb0/1.4       Mfg:"Wizard" Product:"Modem/ISDN"
NConfigs:3 Config:1 : V.90 Analog Modem
usb0/1.5       Mfg:"Iomega" Product:"USB Zip 250"
NConfigs:1 Config:0 : Default
usb0/1.6       Mfg:"SOLID YEAR" Product:"SOLID YEAR
USB"NConfigs:1 Config:0 <no cfg str descr>
usb0/1.7
```

Lines containing only an `ap_id` are empty ports. These can be filtered out. This example only lists USB `ap_ids` with connected devices, and information about those devices.

```
# cfgadm -l -s "select=class(usb),cols=ap_id:info" | grep Mfg
usb0/1         Mfg:<undefined> Product:<undefined>
NConfigs:1 Config:0 <no cfg str descr>
usb0/1.1       Mfg:<undefined> Product:<undefined>
NConfigs:1 Config:0 <no cfg str descr>
usb0/1.4       Mfg:"Wizard" Product:"Modem/ISDN"
NConfigs:3 Config:1 : V.90 Analog Modem
usb0/1.5       Mfg:"Iomega" Product:"USB Zip 250"
NConfigs:1 Config:0 : Default
usb0/1.6       Mfg:"SOLID YEAR" Product:"SOLID YEAR USB"
```

cfgadm_usb(1M)

EXAMPLE 9 Displaying Detailed Information About All USB Devices on the System
(Continued)

```
Config:0 <no cfg str descr>
```

EXAMPLE 10 Listing Information About a Multi-Configuration USB Device

The following example lists information about a multi-configuration USB device.

Note the `NConfigs` field: the configurations available for this device are 0, 1, and 2 (0 to $(NConfigs-1)$).

```
# cfgadm -l -s "cols=ap_id:info" usb0/1.4
Ap_Id          Information
usb0/1.4      Mfg:"Wizard"  Product:"Modem/ISDN"
NConfigs:3   Config:1 V.90 Analog Modem"
```

EXAMPLE 11 Setting the Current Configuration of a Multi-Configuration USB Device

The following example sets the current configuration of a multi-configuration USB device.

`iManufacturer` and `iProduct` should be checked to ensure that the right instance of a device is being referred to, in the case of multiple devices of the exact same type are on the same bus. This information is available in the `Information` field.

```
# cfgadm -o config=2 -x usb_config usb0/1.4
Setting the device: /devices/pci@1f,2000/usb@1/device@3
to USB configuration 2
This operation will suspend activity on the USB device
Continue (yes/no)?
```

Enter:

Y

USB configuration changed successfully.

FILES /usr/lib/cfgadm/usb.so.1

Hardware specific library for generic USB device administration

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWusb (32-bit) SUNWusbx (64-bit)

cfgadm_usb(1M)

SEE ALSO `cfgadm(1M)`, `vold(1M)`, `config_admin(3CFGADM)`, `getopt(3C)`, `attributes(5)`, `usba(7D)`, `scsa2usb(7D)`

Universal Serial Bus 1.1 Specification (www.usb.org)

System Administration Guide, Volume 1

NOTES `cfgadm(1M)` can not unconfigure, disconnect, reset, or change the configuration of any USB device currently opened by `vold(1M)` or any other application. These operations also fail on a hub if a device in its hierarchy is opened by an application. See `scsa2usb(7D)` for unconfiguring a USB mass-storage device that is being used by `vold(1M)`.

Only superusers can execute all but list functions on an attachment point.

cfsadmin(1M)

NAME	<code>cfsadmin</code> – administer disk space used for caching file systems with the Cache File-System (CacheFS)
SYNOPSIS	<pre>cfsadmin -c [-o <i>cacheFS-parameters</i>] <i>cache_directory</i> cfsadmin -d {<i>cache_ID</i> <i>all</i>} <i>cache_directory</i> cfsadmin -l <i>cache_directory</i> cfsadmin -s {<i>mntpt1 ...</i>} <i>all</i> cfsadmin -u [-o <i>cacheFS-parameters</i>] <i>cache_directory</i></pre>
DESCRIPTION	<p>The <code>cfsadmin</code> command provides the following functions:</p> <ul style="list-style-type: none">■ cache creation■ deletion of cached file systems■ listing of cache contents and statistics■ resource parameter adjustment when the file system is unmounted. <p>You must always supply an option for <code>cfsadmin</code>. For each form of the command except <code>-s</code>, you must specify a cache directory, that is, the directory under which the cache is actually stored. A path name in the front file system identifies the cache directory. For the <code>-s</code> form of the command, you must specify a mount point.</p> <p>You can specify a cache ID when you mount a file system with CacheFS, or you can let the system generate one for you. The <code>-l</code> option includes the cache ID in its listing of information. You must know the cache ID to delete a cached file system.</p>
OPTIONS	<pre>-c [-o <i>cacheFS-parameters</i>] <i>cache_directory</i> Create a cache under the directory specified by <i>cache_directory</i>. This directory must not exist prior to cache creation.</pre> <pre>-d { <i>cache_ID</i> <i>all</i> } <i>cache_directory</i> Remove the file system whose cache ID you specify and release its resources, or remove all file systems in the cache by specifying <i>all</i>. After deleting a file system from the cache, you must run the <code>fsck_cacheFs(1M)</code> command to correct the resource counts for the cache.</pre> <p>As indicated by the syntax above, you must supply either a <i>cache_ID</i> or <i>all</i>, in addition to <i>cache_directory</i>.</p> <pre>-l <i>cache_directory</i> List file systems stored in the specified cache, as well as statistics about them. Each cached file system is listed by cache ID. The statistics document resource utilization and cache resource parameters.</pre> <pre>-s { <i>mntpt1 ...</i> } <i>all</i> Request a consistency check on the specified file system (or all <code>cacheFs</code> mounted file systems). The <code>-s</code> option will only work if the cache file system was mounted with <code>demandconst</code> enabled (see <code>mount_cacheFs(1M)</code>). Each file in the specified cache file system is checked for consistency with its corresponding file in the back file system. Note that the consistency check is performed file by file as files are</pre>

accessed. If no files are accessed, no checks are performed. Use of this option does not result in a sudden "storm" of consistency checks.

As indicated by the syntax above, you must supply one or more mount points, or all.

`-u [-o cacheFS-parameters] cache_directory`

Update resource parameters of the specified cache directory. Parameter values can only be increased. To decrease the values, you must remove the cache and recreate it. All file systems in the cache directory must be unmounted when you use this option. Changes will take effect the next time you mount any file system in the specified cache directory. The `-u` option with no `-o` option sets all parameters to their default values.

CacheFS Resource Parameters

You can specify the following CacheFS resource parameters as arguments to the `-o` option. Separate multiple parameters with commas.

<code>maxblocks=<i>n</i></code>	Maximum amount of storage space that CacheFS can use, expressed as a percentage of the total number of blocks in the front file system. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the space the <code>maxblocks</code> parameter allows will be available. The default is 90.
<code>minblocks=<i>n</i></code>	Minimum amount of storage space, expressed as a percentage of the total number of blocks in the front file system, that CacheFS is always allowed to use without limitation by its internal control mechanisms. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the space the <code>minblocks</code> parameter attempts to reserve will be available. The default is 0.
<code>threshblocks=<i>n</i></code>	A percentage of the total blocks in the front file system beyond which CacheFS cannot claim resources once its block usage has reached the level specified by <code>minblocks</code> . The default is 85.
<code>maxfiles=<i>n</i></code>	Maximum number of files that CacheFS can use, expressed as a percentage of the total number of inodes in the front file system. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the inodes the <code>maxfiles</code> parameter allows will be available. The default is 90.
<code>minfiles=<i>n</i></code>	Minimum number of files, expressed as a percentage of the total number of inodes in the front file system, that CacheFS is always allowed to use without limitation by its internal control mechanisms. If CacheFS does not have exclusive use of the front file system, there is no

cfsadmin(1M)

		guarantee that all the inodes the <code>minfiles</code> parameter attempts to reserve will be available. The default is 0.
	<code>threshfiles=<i>n</i></code>	A percentage of the total inodes in the front file system beyond which CacheFS cannot claim inodes once its usage has reached the level specified by <code>minfiles</code> . The default is 85.
	<code>maxfilesize=<i>n</i></code>	Largest file size, expressed in megabytes, that CacheFS is allowed to cache. The default is 3. You cannot decrease the block or inode allotment for a cache. To decrease the size of a cache, you must remove it and create it again with different parameters. Currently <code>maxfilesize</code> is ignored by <code>cachefs</code> , therefore, setting it will have no effect.
OPERANDS	<code>cache_directory</code>	The directory under which the cache is actually stored.
	<code>mntpt1</code>	The directory where the CacheFS is mounted.
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>cfsadmin</code> when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).	
EXAMPLES	EXAMPLE 1 Creating a cache directory. The following example creates a cache directory named <code>/cache</code> : <pre>example# cfsadmin -c /cache</pre>	
	EXAMPLE 2 Creating a cache specifying <code>maxblocks</code> , <code>minblocks</code> and <code>threshblocks</code> . The following example creates a cache named <code>/cache1</code> that can claim a maximum of 60 percent of the blocks in the front file system, can use 40 percent of the front file system blocks without interference by CacheFS internal control mechanisms, and has a threshold value of 50 percent. The threshold value indicates that after CacheFS reaches its guaranteed minimum, it cannot claim more space if 50 percent of the blocks in the front file system are already used. <pre>example# cfsadmin -c -o maxblocks=60,minblocks=40, threshblocks=50 /cache1</pre>	
	EXAMPLE 3 Changing the <code>maxfilesize</code> parameter. The following example changes the <code>maxfilesize</code> parameter for the cache directory <code>/cache2</code> to 2 megabytes: <pre>example# cfsadmin -u -o maxfilesize=2 /cache2</pre>	

EXAMPLE 3 Changing the `maxfilesize` parameter. (Continued)

EXAMPLE 4 Listing the contents of a cache directory.

The following example lists the contents of a cache directory named `/cache3` and provides statistics about resource utilization:

```
example# cfsadmin -l /cache3
```

EXAMPLE 5 Removing a cached file system.

The following example removes the cached file system with cache ID 23 from the cache directory `/cache3` and frees its resources (the cache ID is part of the information returned by `cfsadmin -l`):

```
example# cfsadmin -d 23 /cache3
```

EXAMPLE 6 Removing all cached file systems.

The following example removes all cached file systems from the cache directory `/cache3`:

```
example# cfsadmin -d all /cache3
```

EXAMPLE 7 Checking for consistency in file systems.

The following example checks for consistency all file systems mounted with `demandconst` enabled. No errors will be reported if no `demandconst` file systems were found.

```
example# cfsadmin -s all
```

EXIT STATUS The following exit values are returned:

```
0          Successful completion.
1          An error occurred.
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

cg14config(1M)

NAME	cg14config – configure the cgfourteen device
SYNOPSIS	<code>/usr/platform/ platform-name /sbin/cg14config [-d device] [-r resolution] [-g gammavalue] [-G gammafile] [-u degammavalue] [-U degammafile]</code>
DESCRIPTION	<p>cg14config sets up state on the selected cgfourteen device. <i>platform-name</i> can be found using the <code>-i</code> option of <code>uname(1)</code>.</p> <p>cg14config is supported only on Desktop SPARCsystems with SX graphics option.</p> <p>The interface, output, and command location are uncommitted and subject to change in future releases.</p>
OPTIONS	<p><code>-d device</code> Use <i>device</i> as the cgfourteen device to configure. Default is <code>/dev/fb</code>.</p> <p><code>-r resolution</code> Use <i>resolution</i> as the desired screen resolution. Resolution is specified in terms of screen width and height (in pixels), and vertical refresh (in hz). Available resolutions are:</p> <ul style="list-style-type: none">1024x768@601024x768@661024x768@701152x900@661152x900@761280x1024@661280x1024@761600x1280@661920x1080@72 <p>The default is the value read from the monitor sense codes. Note that some or all of the resolutions above may not be supported by any given monitor. If a programmed resolution is outside of the range of allowable values for a monitor, unpredictable results can occur, including damage to the monitor. Thus, care should be taken when programming the resolution. See <i>Openboot Command Reference</i> for a description of how to reset the console device to the default value if it becomes unusable from programming an unsupported resolution.</p> <p>The <code>-r</code> option is not available when the window system is running.</p> <p><code>-g gammavalue</code> Each entry of the gamma lookup table will be loaded with entry^{1/gammavalue}. The gamma lookup table has 256 entries. Default <i>gammavalue</i> is 2.2.</p> <p><code>-G filename</code> Initialize the gamma lookup table with the contents of <i>filename</i>. The format of <i>filename</i> is 256 triplets (red green</p>

blue) of non-negative integers separated by NEWLINE characters. The integers must be in the range 0 to 1023, inclusive.

-u *degammavalue* Each entry of the degamma lookup table will be loaded with entry[^](*degammavalue*). The degamma lookup table has 256 entries. Default *degammavalue* is 2 . 2.

-U *filename* Initialize the degamma lookup table with the contents of *filename*. The format of *filename* is 256 entries of non-negative integers separated by NEWLINE characters. The integers must be in the range 0 to 255, inclusive.

EXIT STATUS cg14config returns 0 on success and a positive integer on failure.

- 1 Selected device is not a cgfourteen device.
- 2 Requested action failed.
- 3 Unsupported resolution.
- 4 Gamma or degamma value out of range.

chat(1M)

NAME	chat – automated conversational exchange tool
SYNOPSIS	chat [<i>options</i>] <i>script</i>
DESCRIPTION	<p>The chat program implements a conversational text-based exchange between the computer and any serial device, including (but not limited to) a modem, an ISDN TA, and the remote peer itself, establishing a connection between the Point-To-Point Protocol daemon (pppd) and the remote pppd process.</p> <p>The chat command is part of Solaris PPP 4.0, an implementation of the Point-to-Point Protocol (PPP) that is based on the Australian National University PPP. For information on licensing terms, refer to the incorporated materials at <code>/var/sadm/pkg/SUNWpppdu/install/copyright</code>.</p>
OPTIONS	<p>The chat command supports the following options:</p> <ul style="list-style-type: none">-f <<i>chat file</i>> Read the chat script from the chat file. This option is mutually exclusive with the chat script parameters. You must have read access to use the file. Multiple lines are permitted in the file. Use the space or horizontal tab characters to separate the strings.-t <<i>timeout</i>> Set the timeout for the expected string to be received. If the string is not received within the time limit, the reply string is not sent. If specified, a 'subexpect' (alternate reply) string can be sent. Otherwise, if no alternate reply strings remain, the chat script fails.. A failed script will cause the chat program to terminate with a non-zero error code.-r <<i>report file</i>> Set the file for output of the report strings. If you use the keyword REPORT, the resulting strings are written to this file. If the -r option is not used and you use the REPORT keyword, the stderr file is used for the report strings.-e Start with the echo option turned on. You turn echo on or off at specific points in the chat script using the ECHO keyword. When echoing is enabled, all output from the modem is echoed to stderr.-E Enables environment variable substitution within chat scripts using the standard <code>\$xxx</code> syntax.-v Request that the chat script execute in a verbose mode. The chat program logs the execution state of the chat script as well as all text received from the modem and output strings sent to the modem. The default is to log through <code>syslog(3C)</code> with facility <code>local2</code>; the logging method is alterable using the -S and -s options.

-V	Request that the <code>chat</code> script be executed in a <code>stderr</code> verbose mode. The <code>chat</code> program logs all text received from the modem and output strings sent to the modem to <code>stderr</code> . <code>stderr</code> is usually the local console at the station running the <code>chat</code> or <code>pppd</code> program.
-s	Use <code>stderr</code> . Log messages from <code>-v</code> and error messages are sent to <code>stderr</code> .
-S	Do not use <code>syslog</code> . By default, error messages are set to <code>syslog</code> . This option prevents log messages from <code>-v</code> and error messages from being sent to <code>syslog</code> .
-T <phone number>	Pass in an arbitrary string (usually a telephone number) that will be substituted for the <code>\T</code> substitution metacharacter in a send string.
-U <phone number 2>	Pass in a second string (usually a telephone number) that will be substituted for the <code>\U</code> substitution metacharacter in a send string. This is useful when dialing an ISDN terminal adapter that requires two numbers.
script	If the script is not specified in a file with the <code>-f</code> option, the script is included as parameters to the <code>chat</code> program.

Chat Script

The `chat` script defines communications. A script consists of one or more "expect-send" pairs of strings separated by spaces, with an optional "subexpect-sendsend" string pair, separated by a dash (as in the following example):

```
ogin:-BREAK-ogin: ppp ssword: hello2u2
```

The example indicates that the `chat` program should expect the string "ogin:". If it fails to receive a login prompt within the time interval allotted, it sends a break sequence to the remote and then expects the string "ogin:". If the first "ogin:" is received, the break sequence is not generated.

Upon receiving the login prompt, the `chat` program sends the string "ppp" and then expects the prompt "ssword:". When the password prompt is received, it sends the password hello2u2.

A carriage return is normally sent following the reply string. It is not expected in the "expect" string unless it is specifically requested by using the `\r` character sequence.

The expect sequence should contain only what is needed to identify the received data. Because it's stored on a disk file, it should not contain variable information. Generally it is not acceptable to look for time strings, network identification strings, or other variable pieces of data as an expect string.

chat(1M)

To correct for characters that are corrupted during the initial sequence, look for the string "ogin:" rather than "login:". The leading "l" character may be received in error, creating problems in finding the string. For this reason, scripts look for "ogin:" rather than "login:" and "ssword:" rather than "password:".

An example of a simple script follows:

```
ogin: ppp ssword: hello2u2
```

The example can be interpreted as: expect ogin:, send ppp, expect ...ssword:, send hello2u2.

When login to a remote peer is necessary, simple scripts are rare. At minimum, you should include sub-expect sequences in case the original string is not received. For example, consider the following script:

```
ogin:--ogin: ppp ssword: hello2u2
```

This script is more effective than the simple one used earlier. The string looks for the same login prompt; however, if one is not received, a single return sequence is sent and then the script looks for login: again. If line noise obscures the first login prompt, send the empty line to generate a login prompt again.

Comments

Comments can be embedded in the chat script. Comment lines are ignored by the chat program. A comment starts with the hash ("#") character in column one. If a # character is expected as the first character of the expect sequence, quote the expect string. If you want to wait for a prompt that starts with a # character, write something like this:

```
# Now wait for the prompt and send logout string  
'# ' logout
```

Sending Data From A File

If the string to send begins with an at sign ("@"), the remainder of the string is interpreted as the name of the file that contains the string. If the last character of the data read is a newline, it is removed. The file can be a named pipe (or fifo) instead of a regular file. This enables chat to communicate with another program, for example, a program to prompt the user and receive a password typed in.

Abort

Many modems report the status of a call as a string. These status strings are often "CONNECTED" or "NO CARRIER" or "BUSY." If the modem fails to connect to the remote, you can terminate the script. Abort strings may be specified in the script using the ABORT sequence. For example:

```
ABORT BUSY ABORT 'NO CARRIER' '' ATZ OK ATDT5551212 CONNECT
```

This sequence expects nothing and sends the string ATZ. The expected response is the string OK. When OK is received, the string ATDT5551212 dials the telephone. The expected string is CONNECT. If CONNECT is received, the remainder of the script is executed. When the modem finds a busy telephone, it sends the string BUSY, causing

the string to match the abort character sequence. The script fails because it found a match to the abort string. If the NO CARRIER string is received, it aborts for the same reason.

Clr_Abort The CLR_ABORT sequence clears previously set ABORT strings. ABORT strings are kept in an array of a pre-determined size; CLR_ABORT reclaims the space for cleared entries, enabling new strings to use that space.

Say The SAY string enables the script to send strings to a user at a terminal via standard error. If chat is being run by pppd and pppd is running as a daemon (detached from its controlling terminal), standard error is normally redirected to the `/etc/ppp/connect-errors` file.

SAY strings must be enclosed in single or double quotes. If carriage return and line feed are required for the output, you must explicitly add them to your string.

The SAY string can provide progress messages to users even with "ECHO OFF." For example, add a line similar to the following to the script:

```
ABORT BUSY
ECHO OFF
SAY "Dialing your ISP...\n"
'' ATDT5551212
TIMEOUT 120
SAY "Waiting up to 2 minutes for connection ..."
CONNECT ''
SAY "Connected, now logging in ...\n"
ogin: account
sword: pass
$ \c
SAY "Logged in OK ... \n"
```

This sequence hides script detail while presenting the SAY string to the user. In this case, you will see:

```
Dialing your ISP...
Waiting up to 2 minutes for connection...Connected, now logging in...
Logged in OK ...
```

Report REPORT is similar to the ABORT string. With REPORT, however, strings and all characters to the next control character (such as a carriage return), are written to the report file.

REPORT strings can be used to isolate a modem's transmission rate from its CONNECT string and return the value to the chat user. Analysis of the REPORT string logic occurs in conjunction with other string processing, such as looking for the expect string. It's possible to use the same string for a REPORT and ABORT sequence, but probably not useful.

Report strings may be specified in the script using the REPORT sequence. For example:

chat(1M)

```
REPORT CONNECT
ABORT BUSY
ATDT5551212 CONNECT
ogin: account
```

The above sequence expects nothing, then sends the string ATDT5551212 to dial the telephone. The expected string is CONNECT. If CONNECT is received, the remainder of the script is executed. In addition, the program writes the string CONNECT to the report file (specified by `-r`) in addition to any characters that follow.

Clr_Report

CLR_REPORT clears previously set REPORT strings. REPORT strings are kept in an array of a pre-determined size; CLR_REPORT reclaims the space for cleared entries so that new strings can use that space.

Echo

ECHO determines if modem output is echoed to `stderr`. This option may be set with the `-e` option, but can also be controlled by the ECHO keyword. The "expect-send" pair ECHO ON enables echoing, and ECHO OFF disables it. With ECHO, you can select which parts of the conversation should be visible. In the following script:

```
ABORT 'BUSY'
ABORT 'NO CARRIER'
"" AT&F
OK\r\n ATD1234567
\r\n \c
ECHO ON
CONNECT \c
ogin: account
```

All output resulting from modem configuration and dialing is not visible, but output is echoed beginning with the CONNECT (or BUSY) message.

Hangup

The HANGUP option determines if a modem hangup is considered as an error. HANGUP is useful for dialing systems that hang up and call your system back. HANGUP can be ON or OFF. When HANGUP is set to OFF and the modem hangs up (for example, following the first stage of logging in to a callback system), chat continues running the script (for example, waiting for the incoming call and second stage login prompt). When the incoming call is connected, use the HANGUP ON string to reinstall normal hang up signal behavior. An example of a simple script follows:

```
ABORT 'BUSY'
"" AT&F
OK\r\n ATD1234567
\r\n \c
CONNECT \c
'Callback login:' call_back_ID
HANGUP OFF
ABORT "Bad Login"
'Callback Password:' Call_back_password
TIMEOUT 120
CONNECT \c
HANGUP ON
ABORT "NO CARRIER"
```

```
ogin:--BREAK--ogin: real_account
```

Timeout The initial timeout value is 45 seconds. Use the `-t` parameter to change the initial timeout value.

To change the timeout value for the next expect string, the following example can be used:

```
'' "AT&F
OK ATDT5551212
CONNECT \c
TIMEOUT 10
ogin:--ogin: username
TIMEOUT 5
assword: hello2u2
```

The example changes the timeout to ten seconds when it expects the login: prompt. The timeout is changed to five seconds when it looks for the password prompt.

Once changed, the timeout value remains in effect until it is changed again.

EOT The EOT special reply string instructs the `chat` program to send an EOT character to the remote. This is equivalent to using `^D\c` as the reply string. The EOT string normally indicates the end-of-file character sequence. A return character is not sent following the EOT. The EOT sequence can be embedded into the send string using the sequence `^D`.

BREAK The BREAK special reply string sends a break condition. The break is a special transmitter signal. Many UNIX systems handle break by cycling through available bit rates, and sending break is often needed when the remote system does not support autobaud. BREAK is equivalent to using `\K\c` as the reply string. You embed the break sequence into the send string using the `\K` sequence.

Escape Sequences Expect and reply strings can contain escape sequences. Reply strings accept all escape sequences, while expect strings accept most sequences. A list of escape sequences is presented below. Sequences that are not accepted by expect strings are indicated.

```
''      Expects or sends a null string. If you send a null string, chat sends the
        return character. If you expect a null string, chat proceeds to the reply
        string without waiting. This sequence can be a pair of apostrophes or quote
        mark characters.

\b      Represents a backspace character.

\c      Suppresses the newline at the end of the reply string. This is the only
        method to send a string without a trailing return character. This sequence
        must be at the end of the send string. For example, the sequence hello\c
        will simply send the characters h, e, l, l, o. (Not valid in expect.)

\d      Delay for one second. The program uses sleep(1) which delays to a
        maximum of one second. (Not valid in expect.)
```

chat(1M)

\K	Insert a BREAK. (Not valid in expect.)
\n	Send a newline or linefeed character.
\N	Send a null character. The same sequence may be represented by \0. (Not valid in expect.)
\p	Pause for 1/10th of a second. (Not valid in expect.)
\q	Suppress writing the string to syslog. The string ?????? is written to the log in its place. (Not valid in expect.)
\r	Send or expect a carriage return.
\s	Represents a space character in the string. Can be used when it is not desirable to quote the strings which contains spaces. The sequence 'HI TIM' and HI\sTIM are the same.
\t	Send or expect a tab character.
\T	Send the phone number string as specified with the -T option. (Not valid in expect.)
\U	Send the phone number 2 string as specified with the -U option. (Not valid in expect.)
\\	Send or expect a backslash character.
\ddd	Collapse the octal digits (ddd) into a single ASCII character and send that character. (\000 is not valid in an expect string.)
^C	Substitute the sequence with the control character represented by C. For example, the character DC1 (17) is shown as ^Q. (Some characters are not valid in expect.)
ENVIRONMENT VARIABLES	Environment variables are available within chat scripts if the -E option is specified on the command line. The metacharacter \$ introduces the name of the environment variable to substitute. If the substitution fails because the requested environment variable is not set, nothing is replaced for the variable.
EXIT STATUS	The chat program terminates with the following completion codes:
0	Normal program termination. Indicates that the script was executed without error to normal conclusion.
1	One or more of the parameters are invalid or an expect string was too large for the internal buffers. Indicates that the program was not properly executed.
2	An error occurred during the execution of the program. This may be due to a read or write operation failing or chat receiving a signal such as SIGINT.
3	A timeout event occurred when there was an expect string without having a "-subsend" string. This indicates that you may not have programmed the

script correctly for the condition or that an unexpected event occurred and the expected string could not be found.

- 4 The first string marked as an ABORT condition occurred.
- 5 The second string marked as an ABORT condition occurred.
- 6 The third string marked as an ABORT condition occurred.
- 7 The fourth string marked as an ABORT condition occurred.
- . . . The other termination codes are also strings marked as an ABORT condition.

To determine which event terminated the script, use the termination code. It is possible to decide if the string "BUSY" was received from the modem versus "NO DIALTONE." While the first event may be retried, the second probably will not succeed during a retry.

check-hostname(1M)

NAME check-hostname – check if sendmail can determine the system’s fully-qualified host name

SYNOPSIS `/usr/lib/mail/sh/check-hostname`

DESCRIPTION The check-hostname script is a migration aid for sendmail(1M). This script tries to determine the local host’s fully-qualified host name (FQHN) in a manner similar to sendmail(1M). If check-hostname is able to determine the FQHN of the local host, it reports success. Otherwise, check-hostname reports how to reconfigure the system so that the FQHN can be properly determined.

FILES

<code>/etc/hosts</code>	host name database
<code>/etc/nsswitch.conf</code>	name service switch configuration file
<code>/etc/resolv.conf</code>	configuration file for name server routines

SEE ALSO sendmail(1M), hosts(4), attributes(5)

NAME	check-permissions – check permissions on mail rerouting files				
SYNOPSIS	<code>/usr/lib/mail/sh/check-permissions</code> [<i>login</i>]				
DESCRIPTION	<p>The <code>check-permissions</code> script is intended as a migration aid for <code>sendmail(1M)</code>. It checks the <code>/etc/mail/sendmail.cf</code> file for all configured alias files, and checks the alias files for <code>:include:</code> files. It also checks for certain <code>.forward</code> files. For each file that <code>check-permissions</code> checks, it verifies that none of the parent directories are group- or world-writable. If any directories are overly permissive, it is reported. Otherwise it reports that no unsafe directories were found.</p> <p>As to which <code>.forward</code> files are checked, it depends on the arguments included on the command line. If no argument is given, the current user's home directory is checked for the presence of a <code>.forward</code> file. If any arguments are given, they are assumed to be valid logins, and the home directory of each one is checked.</p> <p>If the special argument <code>ALL</code> is given, the <code>passwd</code> entry in the <code>/etc/nsswitch.conf</code> file is checked, and all password entries that can be obtained through the switch file are checked. In large domains, this can be time-consuming.</p>				
OPERANDS	<p>The following operands are supported:</p> <p><i>login</i> Where <i>login</i> is a valid user name, checks the home directory for <i>login</i>.</p> <p><code>ALL</code> Checks the home directory of <i>all</i> users.</p>				
FILES	<p><code>/etc/mail/sendmail.cf</code> defines environment for <code>sendmail</code></p> <p><code>/etc/mail/aliases</code> ascii mail aliases file</p>

chown(1M)

NAME | chown – change owner

SYNOPSIS | `/usr/ucb/chown [-f] [-R] owner [group] filename...`

DESCRIPTION | chown changes the owner of the *filenames* to *owner*. The owner may be either a decimal user ID (UID) or a login name found in the password file. An optional *group* may also be specified. The group may be either a decimal group ID (GID) or a group name found in the GID file.

Only the super-user of the machine where the file is physically located can change owner, in order to simplify accounting procedures.

OPTIONS | -f Do not report errors.
-R Recursively descend into directories setting the ownership of all files in each directory encountered. When symbolic links are encountered, their ownership is changed, but they are not traversed.

FILES | /etc/passwd password file

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO | `chgrp(1)`, `chown(2)`, `group(4)`, `passwd(4)`, `attributes(5)`

NAME	chroot – change root directory for a command				
SYNOPSIS	<code>/usr/sbin/chroot newroot command</code>				
DESCRIPTION	<p>The <code>chroot</code> utility causes <i>command</i> to be executed relative to <i>newroot</i>. The meaning of any initial slashes (<code> </code>) in the path names is changed to <i>newroot</i> for <i>command</i> and any of its child processes. Upon execution, the initial working directory is <i>newroot</i>.</p> <p>Notice that redirecting the output of <i>command</i> to a file,</p> <pre>chroot newroot command >x</pre> <p>will create the file <code>x</code> relative to the original root of <i>command</i>, not the new one.</p> <p>The new root path name is always relative to the current root. Even if a <code>chroot</code> is currently in effect, the <i>newroot</i> argument is relative to the current root of the running process.</p> <p>This command can be run only by the super-user.</p>				
RETURN VALUES	The exit status of <code>chroot</code> is the return value of <i>command</i> .				
EXAMPLES	<p>EXAMPLE 1 Using the <code>chroot</code> utility.</p> <p>The <code>chroot</code> utility provides an easy way to extract <code>tar</code> files (see <code>tar(1)</code>) written with absolute filenames to a different location:</p> <pre>example# cp /usr/sbin/static/tar /tmp example# dd if=/dev/nrst0 chroot /tmp tar xvf -</pre> <p>Note that <code>tar</code> is statically linked, so it is not necessary to copy any shared libraries to the <i>newroot</i> filesystem.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>cd(1)</code> , <code>tar(1)</code> , <code>chroot(2)</code> , <code>ttyname(3C)</code> , <code>attributes(5)</code>				
NOTES	<p>Exercise extreme caution when referencing device files in the new root file system.</p> <p>References by routines such as <code>ttyname(3C)</code> to <code>stdin</code>, <code>stdout</code>, and <code>stderr</code> will find that the device associated with the file descriptor is unknown after <code>chroot</code> is run.</p>				

cimworkshop(1M)

NAME	cimworkshop – start the Sun WBEM CIM WorkShop application								
SYNOPSIS	<code>/usr/sadm/bin/cimworkshop</code>								
DESCRIPTION	<p>The <code>cimworkshop</code> command starts Sun WBEM CIM WorkShop, a graphical user interface that enables you to create, modify, and view the classes and instances that describe the managed resources on your system.</p> <p>Managed resources are described using a standard information model called Common Information Model (CIM). A CIM class is a computer representation, or model, of a type of managed resource, such as a printer, disk drive, or CPU. A CIM instance is a particular managed resource that belongs to a particular class. Instances contain actual data. Objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.</p> <p>The CIM WorkShop application displays a Login dialog box. Context help is displayed on the left side of the CIM WorkShop dialog boxes. When you click on a field, the help content changes to describe the selected field.</p> <p>By default, CIM WorkShop uses the RMI protocol to connect to the CIM Object Manager on the local host, in the default namespace, <code>root\cimv2</code>. You can select HTTP if you want to communicate to a CIM Object Manager using the standard XML/HTTP protocol from the Desktop Management Task Force. When a connection is established, all classes contained in the default namespace are displayed in the left side of the CIM WorkShop window.</p> <p>The name of the current namespace is listed in the tool bar. All programming operations are performed within a namespace. Four namespaces are created in a <code>root</code> namespace during installation:</p> <table><tr><td><code>cimv2</code></td><td>Contains the default CIM classes that represent managed resources on your system.</td></tr><tr><td><code>security</code></td><td>Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.</td></tr><tr><td><code>system</code></td><td>Contains properties for configuring the CIM Object Manager.</td></tr><tr><td><code>snmp</code></td><td>Contains pre-defined SNMP-related classes and all SNMP MOF files that are compiled.</td></tr></table> <p>The <code>cimworkshop</code> application allows you to perform the following tasks:</p> <p>Create, view, and change namespaces. Use the CIM WorkShop application to view all namespaces. A namespace is a directory-like structure that can store CIM classes and instances.</p> <p>Create, delete, and view CIM classes. You cannot modify the unique attributes of the classes that make up the CIM and Solaris Schema. You can create a new instance or subclass of the class and modify the desired attributes in that instance or subclass.</p>	<code>cimv2</code>	Contains the default CIM classes that represent managed resources on your system.	<code>security</code>	Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.	<code>system</code>	Contains properties for configuring the CIM Object Manager.	<code>snmp</code>	Contains pre-defined SNMP-related classes and all SNMP MOF files that are compiled.
<code>cimv2</code>	Contains the default CIM classes that represent managed resources on your system.								
<code>security</code>	Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.								
<code>system</code>	Contains properties for configuring the CIM Object Manager.								
<code>snmp</code>	Contains pre-defined SNMP-related classes and all SNMP MOF files that are compiled.								

Create, modify, delete, and view CIM instances.

You can add instances to a class and modify its inherited properties or create new properties. You can also change the property values of a CIM instance.

Invoke methods.

You can set input values for a parameter of a method and invoke the method.

When CIM WorkShop connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When you use CIM WorkShop to view CIM data, the WBEM system validates your login information on the current host. By default, a validated WBEM user is granted read access to the CIM Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

Read Only	Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
Read/Write	Allows full read, write, and delete access to all CIM classes and instances.
Write	Allows write and delete, but not read access to all CIM classes and instances.
None	Allows no access to CIM classes and instances.

USAGE The `cimworkshop` command is not a tool for a distributed environment. Rather, this command is used for local administration on the machine on which the CIM Object Manager is running.

EXIT STATUS The `cimworkshop` utility terminates with exit status 0.

clear_locks(1M)

NAME	clear_locks – clear locks held on behalf of an NFS client
SYNOPSIS	<code>/usr/sbin/clear_locks [-s] hostname</code>
DESCRIPTION	<p>The <code>clear_locks</code> command removes all file, record, and share locks created by the <i>hostname</i> and held on the current host, regardless of which process created or owns the locks.</p> <p>This command can be run only by the super-user.</p> <p>This command should only be used to repair the rare case of a client crashing and failing to clear held locks. Clearing locks held by an active client may cause applications to fail in an unexpected manner.</p>
OPTIONS	<p><code>-s</code> Remove all locks created by the current machine and held by the server <i>hostname</i>.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>hostname</i> name of host server</p>
EXIT STATUS	<p>0 Successful operation.</p> <p>1 If not root.</p> <p>2 Usage error.</p> <p>3 If unable to contact server (RPC).</p>
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	clinfo – display cluster information				
SYNOPSIS	clinfo [-nh]				
DESCRIPTION	<p>The <code>clinfo</code> command displays cluster configuration information about the node from which the command is executed.</p> <p>Without arguments, <code>clinfo</code> returns an exit status of 0 if the node is configured and booted as part of a cluster. Otherwise, <code>clinfo</code> returns an exit status of 1.</p>				
OPTIONS	<p>The following options are supported:</p> <p>-h Displays the highest node number allowed in the cluster. This is different from the maximum number of nodes supported in a given cluster. For example, <code>clinfo -h</code> might return 64, meaning that the highest number you can use to identify a node is 64. See the <i>Sun Cluster 3.0 System Administration Guide</i> for a description of utilities you can use to determine the number of nodes in a cluster.</p> <p>-n Prints the number of the node from which <code>clinfo</code> is executed.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p> <p>This is usually because the node is not configured or booted as part of a cluster.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

clri(1M)

NAME	clri, dcopy – clear inode				
SYNOPSIS	clri [-F <i>FSType</i>] [-V] <i>special i-number</i> dcopy [-F <i>FSType</i>] [-V] <i>special i-number</i>				
DESCRIPTION	<p>clri writes zeros on the inodes with the decimal <i>i-number</i> on the file system stored on <i>special</i>. After clri, any blocks in the affected file show up as missing in an fsck(1M) of <i>special</i>.</p> <p>Read and write permission is required on the specified file system device. The inode becomes allocatable.</p> <p>The primary purpose of this routine is to remove a file that for some reason appears in no directory. If it is used to zap an inode that does appear in a directory, care should be taken to track down the entry and remove it. Otherwise, when the inode is reallocated to some new file, the old entry will still point to that file. At that point, removing the old entry will destroy the new file. The new entry will again point to an unallocated inode, so the whole cycle is likely to be repeated again and again.</p> <p>dcopy is a symbolic link to clri.</p>				
OPTIONS	<p>-F <i>FSType</i> Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from /etc/vfstab by matching <i>special</i> with an entry in the table, or by consulting /etc/default/fs.</p> <p>-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option should be used to verify and validate the command line.</p>				
USAGE	See largefile(5) for the description of the behavior of clri and dcopy when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).				
FILES	<p>/etc/default/fs Default local file system type</p> <p>/etc/vfstab List of default parameters for each file system</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	fsck(1M), vfstab(4), attributes(5), largefile(5)				
NOTES	This command might not be supported for all <i>FSTypes</i> .				

NAME	consadm – select or display devices used as auxiliary console devices
SYNOPSIS	<pre> /usr/sbin/consadm /usr/sbin/consadm [-a <i>device</i> . . .] [-p] /usr/sbin/consadm [-d <i>device</i> . . .] [-p] /usr/sbin/consadm [-p] </pre>
DESCRIPTION	<p>consadm selects the hardware <i>device</i> or devices to be used as auxiliary console devices, or displays the current device. Only superusers are allowed to make or display auxiliary console device selections.</p> <p>Auxiliary console devices receive copies of <code>console</code> messages, and can be used as the console during <code>single user</code> mode. In particular, they receive kernel messages and messages directed to <code>/dev/sysmsg</code>. On Solaris or IA based systems they can also be used for interaction with the bootstrap.</p> <p>By default, selecting a display device to be used as an auxiliary console device selects that device for the duration the system remains up. If the administrator needs the selection to persist across reboots the <code>-p</code> option can be specified.</p> <p>consadm runs a daemon in the background, monitoring auxiliary console devices. Any devices that are disconnected (hang up, lose carrier) are removed from the auxiliary console device list, though not from the persistent list. While auxiliary console devices may have been removed from the device list receiving copies of <code>console</code> messages, those messages will always continue to be displayed by the default console device.</p> <p>The daemon will not run if it finds there are not any auxiliary devices configured to monitor. Likewise, after the last auxiliary console is removed, the daemon will shut itself down. Therefore the daemon persists for only as long as auxiliary console devices remain active.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-a <i>device</i></code> Adds <i>device</i> to the list of auxiliary console devices. Specify <i>device</i> as the path name to the device or devices to be added to the auxiliary console device list. <code>-d <i>device</i></code> Removes <i>device</i> from the list of auxiliary console devices. Specify <i>device</i> as the path name to the device or devices to be removed from the auxiliary console device list. <code>-p</code> Prints the list of auxiliary consoles that will be auxiliary across reboots. <p>When invoked with the <code>-a</code> or <code>-d</code> options , tells the application to make the change persist across reboot.</p>

consadm(1m)

EXAMPLES

EXAMPLE 1 Adding to the list of devices that will receive console messages

The following command adds `/dev/term/a` to the list of devices that will receive console messages.

```
example# consadm -a /dev/term/a
```

EXAMPLE 2 Removing from the list of devices that will receive console messages

The following command removes `/dev/term/a` from the list of devices that will receive console messages. This includes removal from the persistent list.

```
example# consadm -d -p /dev/term/a
```

EXAMPLE 3 Printing the list of devices selected as auxiliary console devices

The following command prints the name or names of the device or devices currently selected as auxiliary console devices.

```
example# consadm
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `consadm`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability Level	Evolving

SEE ALSO

`eeprom(1M)`, `syslogd(1M)`, `kadb(1M)`, `environ(5)`, `attributes(5)`, `sysmsg(7d)`, `console(7d)`

NOTES

Auxiliary console devices are not usable for `kadb` or firmware I/O, do not receive panic messages, and do not receive output directed to `/dev/console`.

NAME	conv_lp – convert LP configuration				
SYNOPSIS	conv_lp [-d <i>dir</i>] [-f <i>file</i>]				
DESCRIPTION	conv_lp reads LP printer configuration information from a directory and converts it to an output file for use with print client software.				
OPTIONS	The following options are supported: -d <i>dir</i> The root (' / ') directory from which LP configuration information is read. The default is root (' / '). -f <i>file</i> The output file to which conv_lp writes the converted LP configuration information. The default is /etc/printers.conf.				
EXAMPLES	<p>EXAMPLE 1 Converting LP Configuration Information from the Default Directory and File</p> <p>The following example converts LP configuration information from directory root (/) to file /etc/printers.conf.</p> <pre>% conv_lp</pre> <p>EXAMPLE 2 Converting LP Configuration Information From a Specified Directory and File</p> <p>The following example converts LP configuration information from directory /export/root/client to file /export/root/client/etc/printers.conf.</p> <pre>% conv_lp -d /export/root/client -f /export/root/client/etc/printers.conf</pre>				
EXIT STATUS	The following exit values are returned: 0 Successful completion. non-zero An error occurred.				
FILES	/etc/printers.conf System printer configuration database.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWpcu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWpcu

Availability	SUNWpcu				
SEE ALSO	lpset(1M), printers.conf(4), attributes(5)				

conv_lpd(1M)

NAME	conv_lpd – convert LPD configuration
SYNOPSIS	conv_lpd [-c printers -c printcap] [-n] <i>file</i>
DESCRIPTION	conv_lpd converts LPD printer configuration information from <i>file</i> to a printers.conf or a printcap file (see printers.conf(4)). <i>file</i> specifies the name of the input file, and can be either in printers.conf or printcap format. If <i>file</i> is in printers.conf format, it converts it to a printcap file. If <i>file</i> is in printcap format, it converts it to a printers.conf file.
OPTIONS	The following options are supported: -c printers -c printcap Specifies the type of output file produced by the conversion. -c printers converts to a printers.conf file. -c printcap converts to a printcap file. -c printers is the default. -n Preserves the namelist during the conversion.
OPERANDS	The following operands are supported: <i>file</i> The file to be converted.
EXAMPLES	EXAMPLE 1 Converting a printcap file to a printers.conf file. The following example converts a printcap file to a printers.conf file. <pre>example% conv_lpd /etc/printcap</pre> EXAMPLE 2 Converting a printcap file to a printers.conf file and preserving the namelist. The following example converts a printcap file to a printers.conf file and preserves the namelist. <pre>example% conv_lpd -c printers -n /etc/printcap</pre> EXAMPLE 3 Converting a printers.conf file to a printcap file and preserving the namelist. The following example converts a printers.conf file to a printcap file and preserves the namelist. <pre>example% conv_lpd -c printcap -n /etc/printers.conf</pre>
EXIT STATUS	The following exit values are returned: 0 Successful completion. non-zero An error occurred.

conv_lpd(1M)

FILES /etc/printers.conf System printer configuration database.
/etc/printcap SunOS 4.x printer capability database.

coreadm(1M)

NAME	<code>coreadm</code> – core file administration																
SYNOPSIS	<code>coreadm</code> [-g <i>pattern</i>] [-i <i>pattern</i>] [-d <i>option...</i>] [-e <i>option...</i>] <code>coreadm</code> [-p <i>pattern</i>] [<i>pid...</i>] <code>coreadm</code> -u																
DESCRIPTION	<p>The <code>coreadm</code> command is used to specify the name and location of core files produced by abnormally-terminating processes. See <code>core(4)</code>.</p> <p>The first form shown in the synopsis can be executed only by the super-user and is used to configure system-wide core file options, including a global core file name pattern and a per-process core file name pattern for the <code>init(1M)</code> process. All such settings are saved in <code>coreadm</code>'s configuration file <code>/etc/coreadm.conf</code> for setting on reboot. See <code>init(1M)</code></p> <p>The second form can be executed by non-privileged users and is used to specify the file name pattern to be used by the operating system when generating a per-process core file.</p> <p>The third form can be executed only by the super-user and is used to update all system-wide core file options based on the contents of <code>/etc/coreadm.conf</code>. Normally this option is used only on reboot by the startup script <code>/etc/init.d/coreadm</code>.</p> <p>A core file name pattern is a normal file system path name with embedded variables, specified with a leading <code>%</code> character, that are expanded from values in effect when a core file is generated by the operating system. The possible variables are:</p> <table><tr><td><code>%p</code></td><td>process-ID</td></tr><tr><td><code>%u</code></td><td>effective user-ID</td></tr><tr><td><code>%g</code></td><td>effective group-ID</td></tr><tr><td><code>%f</code></td><td>executable file name</td></tr><tr><td><code>%n</code></td><td>system node name (<code>uname -n</code>)</td></tr><tr><td><code>%m</code></td><td>machine name (<code>uname -m</code>)</td></tr><tr><td><code>%t</code></td><td>decimal value of <code>time(2)</code></td></tr><tr><td><code>%%</code></td><td>literal <code>%</code></td></tr></table> <p>For example, the core file name pattern:</p> <pre>/var/core/core.%f.%p</pre> <p>would result, for command <code>foo</code> with process-ID 1234, in the core file name:</p> <pre>/var/core/core.foo.1234</pre> <p>The <code>coreadm</code> command with no arguments reports the current system configuration, for example:</p>	<code>%p</code>	process-ID	<code>%u</code>	effective user-ID	<code>%g</code>	effective group-ID	<code>%f</code>	executable file name	<code>%n</code>	system node name (<code>uname -n</code>)	<code>%m</code>	machine name (<code>uname -m</code>)	<code>%t</code>	decimal value of <code>time(2)</code>	<code>%%</code>	literal <code>%</code>
<code>%p</code>	process-ID																
<code>%u</code>	effective user-ID																
<code>%g</code>	effective group-ID																
<code>%f</code>	executable file name																
<code>%n</code>	system node name (<code>uname -n</code>)																
<code>%m</code>	machine name (<code>uname -m</code>)																
<code>%t</code>	decimal value of <code>time(2)</code>																
<code>%%</code>	literal <code>%</code>																

```
$ coreadm
  global core file pattern: /var/core/core.%f.%p
  init core file pattern: core
    global core dumps: enabled
  per-process core dumps: enabled
  global setid core dumps: enabled
per-process setid core dumps: disabled
  global core dump logging: disabled
```

The `coreadm` command with only a list of process-IDs reports each process's per-process core file name pattern, for example:

```
$ coreadm 278 5678
  278:   core.%f.%p
  5678: /home/george/cores/%f.%p.%t
```

Only the owner of a process or the super-user can interrogate a process in this manner.

When a process is dumping core, the operating system will generate two possible core files, the global core file and the per-process core file. Both files, one or the other, or no file will be generated, based on the system options in effect at the time.

When generated, a global core file will be created mode `600` and will be owned by the super-user. Non-privileged users cannot examine such files.

Ordinary per-process core files are created mode `600` under the credentials of the process. The owner of the process can examine such files.

A process that is or ever has been `setuid` or `setgid` since its last `exec(2)`, including a process that began life with super-user privileges and gave up that privilege by way of `setuid(2)`, presents security issues with respect to dumping core, as it may contain sensitive information in its address space to which the current non-privileged owner of the process should not have access. If setid core files are enabled, they will be created mode `600` and will be owned by the super-user.

OPTIONS The following options are supported:

- g *pattern* Set the global core file name pattern to *pattern*. The pattern must start with a / and can contain any of the special % variables described in the DESCRIPTION.
- Only super-users can use this option.
- i *pattern* Set the per-process core file name *pattern* for `init(1M)` to *pattern*. This is the same as `coreadm -p pattern 1` except that the setting will be persistent across reboot.
- Only super-users can use this option.
- e *option...* Enable the specified core file option. Specify *option* as one of the following:
- global Allow core dumps using global core pattern

coreadm(1M)

	process	Allow core dumps using per-process core pattern
	global-setid	Allow set-id core dumps using global core pattern
	proc-setid	Allow set-id core dumps using per-process core pattern
	log	Generate a <code>syslog(3C)</code> message when generation of a global core file is attempted. Multiple <code>-e</code> and <code>-d</code> options can be specified on the command line. Only super-users can use this option.
<code>-d option...</code>		Disable the specified core file option. See the <code>-e option</code> for descriptions of possible options.
		Multiple <code>-e</code> and <code>-d</code> options can be specified on the command line. Only super-users can use this option.
<code>-p pattern</code>		Set the per-process core file name pattern to <i>pattern</i> for each of the specified process-IDs. The pattern can contain any of the special % variables described in the <code>DESCRIPTION</code> and need not begin with /. If it does not begin with /, it will be evaluated relative to the current directory in effect when the process generates a core file.
		A non-privileged user can apply the <code>-p</code> option only to processes owned by that user. The super-user can apply it to any process. The per-process core file name pattern will be inherited by future child processes of the affected processes. See <code>fork(2)</code> .
<code>-u</code>		Update system-wide core file options from the contents of the configuration file <code>/etc/coreadm.conf</code> . If the configuration file is missing or contains invalid values, default values are substituted. Following the update, the configuration file is resynchronized with the system core file configuration. Only super-users can use this option.

OPERANDS The following operands are supported:

pid process-ID

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- 1 A fatal error occurred while either obtaining or modifying the system core file configuration.
- 2 Invalid command line options were specified.

EXAMPLES **EXAMPLE 1** Setting the core file name pattern

When executed from a user's `$HOME/.profile` or `$HOME/.login`, the following command sets the core file name pattern for all processes run during the login session:

EXAMPLE 1 Setting the core file name pattern *(Continued)*

```
example$ coreadm -p core.%f.%p $$
```

\$\$ is the process-id of the currently running shell. The per-process core file name pattern is inherited by all child processes.

EXAMPLE 2 Dumping user's files into a subdirectory

The following command dumps all of the user's core dumps into the `corefiles` subdirectory of the home directory, discriminated by the system node name. This is useful for users who use many different machines but have a shared home directory.

```
example$ coreadm -p $HOME/corefiles/%n.%f.%p $$
```

cpustat(1M)

NAME	<code>cpustat</code> – monitor system behavior using CPU performance counters
SYNOPSIS	<code>cpustat -c <i>eventspec</i> [-c <i>eventspec</i>]... [-ntD] [<i>interval</i> [<i>count</i>]]</code> <code>cpustat -h</code>
DESCRIPTION	<p>The <code>cpustat</code> utility allows CPU performance counters to be used to monitor the overall behavior of the CPUs in the system.</p> <p>If <i>interval</i> is specified, <code>cpustat</code> samples activity every <i>interval</i> seconds, repeating forever. If a <i>count</i> is specified, the statistics are repeated <i>count</i> times. If neither are specified, an interval of five seconds is used, and there is no limit to the number of samples that will be taken.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-c <i>eventspec</i></code> Specifies a set of events for the CPU performance counters to monitor. The syntax of these event specification can be determined using the <code>-h</code> option to cause the usage message to be generated. The semantics of these event specifications can be determined by reading the CPU manufacturers documentation for the events. See <code>cpc_strtoevent(3CPC)</code> for a description of the syntax.Multiple <code>-c</code> options may be specified, in which case the command cycles between the different event settings on each sample.<code>-D</code> Enables debug mode.<code>-h</code> Prints an extensive help message on how to use the utility and how to program the processor-dependent counters.<code>-n</code> Omits all header output (useful if <code>cpustat</code> is the beginning of a pipeline).<code>-t</code> Prints an additional column of processor cycle counts, if available on the current architecture.
USAGE	<p>A closely related utility, <code>cputrack(1)</code>, can be used to monitor the behavior of individual applications with little or no interference from other activities on the system.</p> <p>The <code>cpustat</code> utility must be run by the super-user, as there is an intrinsic conflict between the use of the CPU performance counters system-wide by <code>cpustat</code> and the use of the CPU performance counters to monitor an individual process (for example, by <code>cputrack</code>.)</p> <p>Once any instance of this utility has started, no further per-process or per-LWP use of the counters is allowed until the last instance of the utility terminates.</p>

The times printed by the command correspond to the wallclock time when the hardware counters were actually sampled, instead of when the program told the kernel to sample them. The time is derived from the same timebase as `gethrtime(3C)`.

The processor cycle counts enabled by the `-t` option always apply to both user and system modes, regardless of the settings applied to the performance counter registers.

On some hardware platforms, the counters are implemented using 32-bit registers. While the kernel attempts to catch all overflows to synthesize 64-bit counters, because of hardware implementation restrictions, overflows may be lost unless the sampling interval is kept short enough. The events most prone to wrap are those that count processor clock cycles. If such an event is of interest, sampling should occur frequently so that less than 4 billion clock cycles can occur between samples.

The output of `cpustat` is designed to be readily parseable by `nawk(1)` and `perl(1)`, thereby allowing performance tools to be composed by embedding `cpustat` in scripts. Alternatively, tools may be constructed directly using the same APIs that `cpustat` is built upon using the facilities of `libcpc(3LIB)`. See `cpc(3CPC)`.

The `cpustat` utility only monitors the CPUs that are accessible to it in the current processor set. Thus, several instances of the utility can be running on the CPUs in different processor sets. See `psrset(1M)` for more information about processor sets.

Because `cpustat` uses LWPs bound to CPUs, the utility may have to be terminated before the configuration of the relevant processor can be changed.

WARNINGS

By running the `cpustat` command, the super-user will forcibly invalidate all existing performance counter context. This may in turn cause all invocations of the `cpustrack` command, and other users of performance counter context, to exit prematurely with unspecified errors.

If `cpustat` is invoked on a system that has CPU performance counters, but on which the packages containing the kernel support for those counters is not installed, the following message appears:

```
cpustat: CPU performance counters are inaccessible on this machine
```

This error message implies that `cpc_access()` has failed and is documented in `cpc_access(3CPC)`. Review this documentation for more information about the problem and possible solutions.

NAME	cron – clock daemon								
SYNOPSIS	<code>/usr/sbin/cron</code>								
DESCRIPTION	<p>The <code>cron</code> command starts a process that executes commands at specified dates and times. Regularly scheduled commands can be specified according to instructions found in <code>crontab</code> files in the directory <code>/var/spool/cron/crontabs</code>. Users can submit their own <code>crontab</code> file using the <code>crontab(1)</code> command. Commands which are to be executed only once may be submitted using the <code>at(1)</code> command.</p> <p><code>cron</code> only examines <code>crontab</code> or <code>at</code> command files during its own process initialization phase and when the <code>crontab</code> or <code>at</code> command is run. This reduces the overhead of checking for new or changed files at regularly scheduled intervals.</p> <p>Since <code>cron</code> never exits, it should be executed only once. This is done routinely through <code>/etc/rc2.d/S75cron</code> at system boot time. The file <code>/etc/cron.d/FIFO</code> is used (among other things) as a lock file to prevent the execution of more than one instance of <code>cron</code>.</p> <p><code>cron</code> captures the output of the job's <code>stdout</code> and <code>stderr</code> streams, and, if it is non-empty, mails the output to the user. If the job does not produce output, no mail is sent to the user (unless the job is an <code>at(1)</code> job and the <code>-m</code> option was specified when the job was submitted).</p>								
Setting cron Defaults	<p>To keep a log of all actions taken by <code>cron</code>, <code>CRONLOG=YES</code> (by default) must be specified in the <code>/etc/default/cron</code> file. If <code>CRONLOG=NO</code> is specified, no logging is done. Keeping the log is a user configurable option since <code>cron</code> usually creates huge log files.</p> <p>The <code>PATH</code> for user <code>cron</code> jobs can be set using <code>PATH=</code> in <code>/etc/default/cron</code>. The <code>PATH</code> for <code>root</code> <code>cron</code> jobs can be set using <code>SUPATH=</code> in <code>/etc/default/cron</code>. The security implications of setting <code>PATH</code> and <code>SUPATH</code> should be carefully considered.</p> <p>Example <code>/etc/default/cron</code> file:</p> <pre>CRONLOG=YES PATH=/usr/bin:/usr/ucb:</pre> <p>This example enables logging and sets the default <code>PATH</code> used by non-root jobs to <code>/usr/bin:/usr/ucb:.</code> Root jobs will continue to use <code>/usr/sbin:/usr/bin</code>.</p> <p><code>/etc/cron.d/logchecker</code> is a script that checks to see if the log file has exceeded the system <code>ulimit</code>. If so, the log file is moved to <code>/var/cron/olog</code>.</p>								
FILES	<table border="0"> <tr> <td><code>/etc/cron.d</code></td> <td>main <code>cron</code> directory</td> </tr> <tr> <td><code>/etc/cron.d/FIFO</code></td> <td>used as a lock file</td> </tr> <tr> <td><code>/etc/default/cron</code></td> <td>contains <code>cron</code> default settings</td> </tr> <tr> <td><code>/var/cron/log</code></td> <td><code>cron</code> history information</td> </tr> </table>	<code>/etc/cron.d</code>	main <code>cron</code> directory	<code>/etc/cron.d/FIFO</code>	used as a lock file	<code>/etc/default/cron</code>	contains <code>cron</code> default settings	<code>/var/cron/log</code>	<code>cron</code> history information
<code>/etc/cron.d</code>	main <code>cron</code> directory								
<code>/etc/cron.d/FIFO</code>	used as a lock file								
<code>/etc/default/cron</code>	contains <code>cron</code> default settings								
<code>/var/cron/log</code>	<code>cron</code> history information								

cron(1M)

<code>/var/spool/cron</code>	pool area
<code>/etc/cron.d/logchecker</code>	moves log file to <code>/var/cron/olog</code> if log file exceeds system ulimit.
<code>/etc/cron.d/queuedefs</code>	queue description file for <code>at</code> , <code>batch</code> , and <code>cron</code> .

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `at(1)`, `crontab(1)`, `sh(1)`, `queuedefs(4)`, `attributes(5)`

DIAGNOSTICS A history of all actions taken by `cron` is stored in `/var/cron/log` and (possibly) `/var/cron/olog`.

NAME	cvcd – virtual console daemon
SYNOPSIS	<code>/platform/platform_name/cvcd</code>
DESCRIPTION	<p>The virtual console daemon, <code>cvcd</code>, is a server process that supports the network console provided on some platforms. The <code>cvcd</code> daemon accepts network console connections from a remote host (only one host at any given time). Console input is read from this connection and forwarded to <code>cvc(7D)</code> by way of <code>cvcredir(7D)</code>.</p> <p>Similarly, console output is read from <code>cvcredir(7D)</code> and forwarded across the network console connection. If <code>cvcd</code> dies, console traffic is automatically rerouted through an internal hardware interface.</p> <p>The <code>cvcd</code> daemon normally starts at system boot time. Each domain supports only one <code>cvcd</code> process at a time.</p> <p>Caution: On Sun Enterprise 10000 domains, <code>cvcd</code> uses a configuration file (<code>/etc/ssphostname</code>) to determine the name of the host from which network console connections are allowed. If the remote console host is renamed, you must edit the configuration file to reflect that change.</p>
OPERANDS	<p>The following operands are supported:</p> <p><code>platform_name</code> The official Sun platform name used in packaging and code. For example, for Sun Fire 15000 servers, the <code>platform_name</code> would be <code>SUNW, Sun-Fire-15000</code>.</p>
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	Sun Enterprise 10000 servers Sun Fire 15000 servers
Availability	SUNWcvc.u

SEE ALSO	<p><code>services(4)</code>, <code>attributes(5)</code>, <code>cvc(7D)</code>, <code>cvcredir(7D)</code></p> <p><i>Sun Enterprise 10000 SSP Reference Manual</i></p> <p><i>Sun System Management Services (SMS) Reference Manual</i></p>
-----------------	--

dcsh(1M)

NAME	dcsh – domain configuration server
SYNOPSIS	<code>/usr/lib/dcs [-s sessions]</code>
DESCRIPTION	<p>The domain configuration server (DCS) is a daemon process that runs on Sun servers that support remote dynamic reconfiguration (DR) clients. It is started by <code>inetd(1M)</code> when the first DR request is received from a client connecting to the network service <code>sun-dr</code>. After the DCS accepts a DR request, it uses the <code>libcfgadm(3LIB)</code> interface to execute the DR operation. After the operation is performed, the results are returned to the client.</p> <p>The DCS listens on the network service labeled <code>sun-dr</code>. Its underlying protocol is TCP, and it is invoked as an <code>inetd</code> server using the TCP transport. The entries for the DCS in the <code>/etc/inet/inetd.conf</code> file are as follows:</p> <pre>sun-dr stream tcp wait root /usr/lib/dcs dcs sun-dr stream tcp6 wait root /usr/lib/dcs dcs</pre> <p>These entries enable remote DR operations. Removing them does not negatively impact the server; however, all DR operations initiated from a remote host would fail.</p>
OPTIONS	<p><code>-s sessions</code> Sets the number of active sessions that the DCS allows at any one time. When the limit is reached, the DCS stops accepting connections until active sessions complete the execution of their DR operation. If this option is not specified, a default value of 128 is used.</p>
ERRORS	<p>The DCS uses <code>syslog(3C)</code> to report status and error messages. All of the messages are logged with the <code>LOG_DAEMON</code> facility. Error messages are logged with the <code>LOG_ERR</code> and <code>LOG_NOTICE</code> priorities, and informational messages are logged with the <code>LOG_INFO</code> priority. The default entries in the <code>/etc/syslog.conf</code> file log all of the DCS error messages to the <code>/var/adm/messages</code> log.</p>
SEE ALSO	<code>cfgadm_sbd(1M)</code> , <code>inetd(1M)</code> , <code>syslog(3C)</code> , <code>config_admin(3CFGADM)</code> , <code>libcfgadm(3LIB)</code> , <code>inetd.conf(4)</code> , <code>syslog.conf(4)</code> , <code>dr(7D)</code>

NAME	dd – convert and copy a file
SYNOPSIS	<code>/usr/bin/dd</code> [<i>operand=value...</i>]
DESCRIPTION	<p>dd copies the specified input file to the specified output with possible conversions. The standard input and output are used by default. The input and output block sizes may be specified to take advantage of raw physical I/O. Sizes are specified in bytes; a number may end with <i>k</i>, <i>b</i>, or <i>w</i> to specify multiplication by 1024, 512, or 2, respectively. Numbers may also be separated by <i>x</i> to indicate multiplication.</p> <p>dd will read the input one block at a time, using the specified input block size; it then will process the block of data actually returned, which could be smaller than the requested block size. dd will apply any conversions that have been specified and write the resulting data to the output in blocks of the specified output block size.</p> <p><i>cbs</i> is used only if <i>ascii</i>, <i>asciib</i>, <i>unblock</i>, <i>ebcdic</i>, <i>ebcdicb</i>, <i>ibm</i>, <i>ibmb</i>, or <i>block</i> conversion is specified. In the first two cases, <i>cbs</i> characters are copied into the conversion buffer, any specified character mapping is done, trailing blanks are trimmed, and a NEWLINE is added before sending the line to output. In the last three cases, characters up to NEWLINE are read into the conversion buffer and blanks are added to make up an output record of size <i>cbs</i>. ASCII files are presumed to contain NEWLINE characters. If <i>cbs</i> is unspecified or 0, the <i>ascii</i>, <i>asciib</i>, <i>ebcdic</i>, <i>ebcdicb</i>, <i>ibm</i>, and <i>ibmb</i> options convert the character set without changing the input file's block structure; the <i>unblock</i> and <i>block</i> options become a simple file copy.</p> <p>After completion, dd reports the number of whole and partial input and output blocks.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>if=file</i> Specify the input path; standard input is the default.</p> <p><i>of=file</i> Specify the output path; standard output is the default. If the <i>seek=expr</i> conversion is not also specified, the output file will be truncated before the copy begins, unless <i>conv=notrunc</i> is specified. If <i>seek=expr</i> is specified, but <i>conv=notrunc</i> is not, the effect of the copy will be to preserve the blocks in the output file over which dd seeks, but no other portion of the output file will be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file will be shortened by the copy.)</p> <p><i>ibs=n</i> Specify the input block size in <i>n</i> bytes (default is 512).</p> <p><i>obs=n</i> Specify the output block size in <i>n</i> bytes (default is 512).</p>

dd(1M)

`bs=n`

Set both input and output block sizes to *n* bytes, superseding `ibs=` and `obs=`. If no conversion other than `sync`, `noerror`, and `notrunc` is specified, each input block will be copied to the output as a single block without aggregating short blocks.

`cbs=n`

Specify the conversion block size for `block` and `unblock` in bytes by *n* (default is 0). If `cbs=` is omitted or given a value of 0, using `block` or `unblock` produces unspecified results.

This option is used only if ASCII or EBCDIC conversion is specified. For the `ascii` and `asciib` operands, the input is handled as described for the `unblock` operand except that characters are converted to ASCII before the trailing SPACE characters are deleted. For the `ebcdic`, `ebcdicb`, `ibm`, and `ibmb` operands, the input is handled as described for the `block` operand except that the characters are converted to EBCDIC or IBM EBCDIC after the trailing SPACE characters are added.

`files=n`

Copy and concatenate *n* input files before terminating (makes sense only where input is a magnetic tape or similar device).

`skip=n`

Skip *n* input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation will read the blocks or seek past them; on non-seekable files, the blocks will be read and the data will be discarded.

`iseek=n`

Seek *n* blocks from beginning of input file before copying (appropriate for disk files, where `skip` can be incredibly slow).

`oseek=n`

Seek *n* blocks from beginning of output file before copying.

`seek=n`

Skip *n* blocks (using the specified output block size) from beginning of output file before copying. On non-seekable files, existing blocks will be read and space from the current end-of-file to the specified offset, if any, filled with null bytes; on seekable files, the implementation will seek to the specified offset or read the blocks as described for non-seekable files.

`count=n`

Copy only *n* input blocks.

`conv=value[, value. . .]`

Where *values* are comma-separated symbols from the following list:

<code>ascii</code>	Convert EBCDIC to ASCII.
<code>asciib</code>	Convert EBCDIC to ASCII using BSD-compatible character translations.

<code>ebcdic</code>	Convert ASCII to EBCDIC. If converting fixed-length ASCII records without NEWLINES, set up a pipeline with <code>dd conv=unblock</code> beforehand.
<code>ebcdicb</code>	Convert ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length ASCII records without NEWLINES, set up a pipeline with <code>dd conv=unblock</code> beforehand.
<code>ibm</code>	Slightly different map of ASCII to EBCDIC. If converting fixed-length ASCII records without NEWLINES, set up a pipeline with <code>dd conv=unblock</code> beforehand.
<code>ibmb</code>	Slightly different map of ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length ASCII records without NEWLINES, set up a pipeline with <code>dd conv=unblock</code> beforehand.

The `ascii` (or `asciib`), `ebcdic` (or `ebcdicb`), and `ibm` (or `ibmb`) values are mutually exclusive.

<code>block</code>	Treat the input as a sequence of NEWLINE-terminated or EOF-terminated variable-length records independent of the input block boundaries. Each record is converted to a record with a fixed length specified by the conversion block size. Any NEWLINE character is removed from the input line; SPACE characters are appended to lines that are shorter than their conversion block size to fill the block. Lines that are longer than the conversion block size are truncated to the largest number of characters that will fit into that size; the number of truncated lines is reported.
<code>unblock</code>	Convert fixed-length records to variable length. Read a number of bytes equal to the conversion block size (or the number of bytes remaining in the input, if less than the conversion block size), delete all trailing SPACE characters, and append a NEWLINE character.

The `block` and `unblock` values are mutually exclusive.

<code>lcase</code>	Map upper-case characters specified by the <code>LC_CTYPE</code> keyword <code>tolower</code> to the corresponding lower-case character. Characters for which no mapping is specified will not be modified by this conversion.
<code>ucase</code>	Map lower-case characters specified by the <code>LC_CTYPE</code> keyword <code>toupper</code> to the corresponding upper-case character. Characters for which no mapping is specified will not be modified by this conversion.

The `lcase` and `ucase` symbols are mutually exclusive.

dd(1M)

swab	Swap every pair of input bytes. If the current input record is an odd number of bytes, the last byte in the input record is ignored.
noerror	Do not stop processing on an input error. When an input error occurs, a diagnostic message will be written on standard error, followed by the current input and output block counts in the same format as used at completion. If the <code>sync</code> conversion is specified, the missing input will be replaced with null bytes and processed normally; otherwise, the input block will be omitted from the output.
notrunc	Do not truncate the output file. Preserve blocks in the output file not explicitly written by this invocation of <code>dd</code> . (See also the preceding <code>of=file</code> operand.)
sync	Pad every input block to the size of the <code>ibs=</code> buffer, appending null bytes. (If either <code>block</code> or <code>unblock</code> is also specified, append SPACE characters, rather than null bytes.)

If operands other than `conv=` are specified more than once, the last specified operand=*value* will be used.

For the `bs=`, `cbs=`, `ibs=`, and `obs=` operands, the application must supply an expression specifying a size in bytes. The expression, `expr`, can be:

1. a positive decimal number
2. a positive decimal number followed by `k`, specifying multiplication by 1024
3. a positive decimal number followed by `b`, specifying multiplication by 512
4. two or more positive decimal numbers (with or without `k` or `b`) separated by `x`, specifying the product of the indicated values.

All of the operands will be processed before any input is read.

USAGE See `largefile(5)` for the description of the behavior of `dd` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Copying From Tape Drive 0 to Tape Drive 1:

The following example copies from tape drive 0 to tape drive 1, using a common historical device naming convention.

```
example% dd if=/dev/rmt/0h of=/dev/rmt/1h
```

EXAMPLE 2 Stripping the First 10 bytes From Standard Input

The following example strips the first 10 bytes from standard input.

```
example% dd ibs=10 skip=1
```

EXAMPLE 2 Stripping the First 10 bytes From Standard Input *(Continued)*

EXAMPLE 3 Reading a Tape Into an ASCII File

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file `x` :

```
example% dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcase
```

EXAMPLE 4 Using `conv=sync` to Write to Tape

The following example uses `conv=sync` when writing to a tape:

```
example% tar cvf - . | compress | dd obs=1024k of=/dev/rmt/0 conv=sync
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `dd`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 The input file was copied successfully.
>0 An error occurred.

If an input error is detected and the `noerror` conversion has not been specified, any partial output block will be written to the output file, a diagnostic message will be written, and the copy operation will be discontinued. If some other error is detected, a diagnostic message will be written and the copy operation will be discontinued.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`cp(1)`, `sed(1)`, `tr(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

DIAGNOSTICS

`f+p records in(out)` numbers of full and partial blocks read(written)

NOTES

Do not use `dd` to copy files between file systems having different block sizes.

Using a blocked device to copy a file will result in extra nulls being added to the file to pad the final block to the block boundary.

When `dd` reads from a pipe, using the `ibs=X` and `obs=Y` operands, the output will always be blocked in chunks of size `Y`. When `bs=Z` is used, the output blocks will be whatever was available to be read from the pipe at the time.

dd(1M)

When using `dd` to copy files to a tape device, the file size must be a multiple of the device sector size (for example, 512 Kbyte). To copy files of arbitrary size to a tape device, use `tar(1)` or `cpio(1)`.

For `SIGINT`, `dd` will write status information to standard error before exiting. It will take the standard action for all other signals.

NAME	devattr – display device attributes				
SYNOPSIS	devattr [-v] <i>device</i> [<i>attribute...</i>]				
DESCRIPTION	devattr displays the values for a device's attributes. The display can be presented in two formats. Used without the -v option, only the attribute values are shown. Used with the -v option, the attributes are shown in an <i>attribute=value</i> format. When no attributes are given on the command line, all attributes for the specified device are displayed in alphabetical order by attribute name. If attributes are given on the command line, only those attributes are shown, displayed in command line order.				
OPTIONS	The following options are supported: -v Specifies verbose format. Attribute values are displayed in an <i>attribute=value</i> format.				
OPERANDS	The following operands are supported: <i>device</i> Defines the device whose attributes should be displayed. Can be the pathname of the device or the device alias. <i>attribute</i> Defines which attribute, or attributes, should be shown. Default is to show all attributes for a device. See the putdev(1M) manual page for a complete listing and description of available attributes.				
EXIT STATUS	The following exit values are returned: 0 successful completion. 1 Command syntax was incorrect, invalid option was used, or an internal error occurred. 2 Device table could not be opened for reading. 3 Requested device could not be found in the device table. 4 Requested attribute was not defined for the specified device.				
FILES	/etc/device.tab				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	getdev(1M), putdev(1M), attributes(5)				

devfree(1M)

NAME	devfree – release devices from exclusive use				
SYNOPSIS	devfree <i>key</i> [<i>device...</i>]				
DESCRIPTION	<p>devfree releases devices from exclusive use. Exclusive use is requested with the command devreserv.</p> <p>When devfree is invoked with only the <i>key</i> argument, it releases all devices that have been reserved for that <i>key</i>. When called with <i>key</i> and <i>device</i> arguments, devfree releases the specified devices that have been reserved with that <i>key</i>.</p>				
OPERANDS	<p>The following operands are supported:</p> <p><i>key</i> Designates the unique key on which the device was reserved.</p> <p><i>device</i> Defines device that this command will release from exclusive use. <i>device</i> can be the pathname of the device or the device alias.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 Command syntax was incorrect, an invalid option was used, or an internal error occurred.</p> <p>2 Device table or device reservation table could not be opened for reading.</p> <p>3 Reservation release could not be completely fulfilled because one or more of the devices was not reserved or was not reserved on the specified key.</p>				
FILES	<p>/etc/device.tab</p> <p>/etc/devlkfile</p>				
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	devreserv(1M), attributes(5)				
NOTES	<p>The commands devreserv and devfree are used to manage the availability of devices on a system. These commands do not place any constraints on the access to the device. They serve only as a centralized bookkeeping point for those who wish to use them. Processes that do not use devreserv may concurrently use a device with a process that has reserved that device.</p>				

NAME	devfsadm, devfsadmd – administration command for /dev and /devices
SYNOPSIS	<pre> /usr/sbin/devfsadm [-C] [-c device_class] [-i driver_name] [-n] [-r root_dir] [-s] [-t table_file] [-v] /usr/lib/devfsadm/devfsadmd </pre>
DESCRIPTION	<p>devfsadm(1M) maintains the /dev and /devices namespaces. It replaces the previous suite of devfs administration tools including drvconfig(1M), disks(1M), tapes(1M), ports(1M), audlinks(1M), and devlinks(1M).</p> <p>The default operation is to attempt to load every driver in the system and attach to all possible device instances. devfsadm then creates device special files in /devices and logical links in /dev.</p> <p>devfsadmd(1M) is the daemon version of devfsadm(1M). The daemon is started by the /etc/rc* scripts during system startup and is responsible for handling both reconfiguration boot processing and updating /dev and /devices in response to dynamic reconfiguration event notifications from the kernel.</p> <p>For compatibility purposes, drvconfig(1M), disks(1M), tapes(1M), ports(1M), audlinks(1M), and devlinks(1M) are implemented as links to devfsadm.</p> <p>In addition to managing /dev and /devices, devfsadm also maintains the path_to_inst(4) database.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -C Cleanup mode. Prompts devfsadm to invoke cleanup routines that are not normally invoked to remove dangling logical links. If -c is also used, devfsadm only cleans up for the listed devices' classes. -c <i>device_class</i> Restrict operations to devices of class <i>device_class</i>. Solaris defines the following values for <i>device_class</i>: disk, tape, port, audio, and pseudo. This option may be specified more than once to specify multiple device classes. -i <i>driver_name</i> Configure only the devices for the named driver, <i>driver_name</i>. -n Do not attempt to load drivers or add new nodes to the kernel device tree. -s Suppress any changes to /dev or /devices. This is useful with the -v option for debugging. -t <i>table_file</i> Read an alternate devlink.tab file. devfsadm normally reads /etc/devlink.tab.

devfsadm(1M)

`-r root_dir` Presume that the `/dev` and `/devices` directory trees are found under `root_dir`, not directly under `root (/)`. No other use or assumptions are made about `root_dir`.

`-v` Print changes to `/dev` and `/devices` in verbose mode.

EXIT STATUS The following exit values are returned:

0 Successful completion.

1 An error occurred.

FILES

devlinks(1M)

NAME	devlinks – adds /dev entries for miscellaneous devices and pseudo-devices								
SYNOPSIS	<code>/usr/sbin/devlinks [-d] [-r rootdir] [-t table-file]</code>								
DESCRIPTION	<p>devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of devlinks.</p> <p>devlinks creates symbolic links from the /dev directory tree to the actual block- and character-special device nodes under the /devices directory tree. The links are created according to specifications found in the <i>table-file</i> (by default /etc/devlink.tab).</p> <p>devlinks is called each time the system is reconfiguration-booted, and can only be run after drvconfig(1M) is run, since drvconfig(1M) builds the kernel data structures and the /devices tree.</p> <p>The <i>table-file</i> (normally /etc/devlink.tab) is an ASCII file, with one line per record. Comment lines, which must contain a hash character ('#') as their first character, are allowed. Each entry must contain at least two fields, but may contain three fields. Fields are separated by single TAB characters.</p> <p>The fields are:</p> <table><tr><td><i>devfs-spec</i></td><td>Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.</td></tr></table> <p>The possible keywords are:</p> <table><tr><td><i>type</i></td><td>The devinfo device type. Possible values are specified in ddi_create_minor_node(9F)</td></tr><tr><td><i>name</i></td><td>The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':' character.</td></tr><tr><td><i>addr[n]</i></td><td>The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the <i>addr</i> it specifies a match of a particular</td></tr></table>	<i>devfs-spec</i>	Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.	<i>type</i>	The devinfo device type. Possible values are specified in ddi_create_minor_node(9F)	<i>name</i>	The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':' character.	<i>addr[n]</i>	The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the <i>addr</i> it specifies a match of a particular
<i>devfs-spec</i>	Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.								
<i>type</i>	The devinfo device type. Possible values are specified in ddi_create_minor_node(9F)								
<i>name</i>	The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':' character.								
<i>addr[n]</i>	The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the <i>addr</i> it specifies a match of a particular								

devlinks(1M)

comma-separated subfield of the address field: *addr1* matches the first subfield, *addr2* matches the second, and so on. *addr0* is the same as *addr* and matches the whole field.

minor[n] The minor portion of a node name – the portion of the name after the ‘:’. As with *addr* above, a number after the *minor* keyword specifies a subfield to match.

Of these four specifications, only the *type* specification must always be present.

name

Specification of the `/dev` links that correspond to the devinfo nodes. This field allows `devlinks` to determine matching `/dev` names for the `/devices` nodes it has found. The specification of this field uses escape-sequences to allow portions of the `/devices` name to be included in the `/dev` name, or to allow a counter to be used in creating node names. If a counter is used to create a name, the portion of the name before the counter must be specified absolutely, and all names in the `/dev/-`subdirectory that match (up to and including the counter) are considered to be subdevices of the same device. This means that they should all point to the same directory, name and address under the `/devices/-tree`

The possible escape-sequences are:

- `\D` Substitute the `device-name` (name) portion of the corresponding devinfo node-name.
- `\An` Substitute the *n*th component of the address component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole address component.
- `\Mn` Substitute the *n*th sub-component of the minor component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole minor component.

devlinks(1M)

	<code>\Nm</code>	<p>Substitute the value of a 'counter' starting at <i>n</i>. There can be only one counter for each dev-spec, and counter-values will be selected so they are as low as possible while not colliding with already-existing link names.</p> <p>In a dev-spec the <code>counter</code> sequence should not be followed by a digit, either explicitly or as a result of another escape-sequence expansion. If this occurs, it would not be possible to correctly match already-existing links to their counter entries, since it would not be possible to unambiguously parse the already-existing <code>/dev-name</code>.</p>
	<i>extra-dev-link</i>	<p>Optional specification of an extra <code>/dev</code> link that points to the initial <code>/dev</code> link (specified in field 2). This field may contain a <code>counter</code> escape-sequence (as described for the <i>dev-spec</i> field) but may not contain any of the other escape-sequences. It provides a way to specify an alias of a particular <code>/dev</code> name.</p>
OPTIONS	<code>-d</code>	<p>Debugging mode – print out all <code>devinfo</code> nodes found, and indicate what links would be created, but do not do anything.</p>
	<code>-r rootdir</code>	<p>Use <i>rootdir</i> as the root of the <code>/dev</code> and <code>/devices</code> directories under which the device nodes and links are created. Changing the root directory does not change the location of the <code>/etc/devlink.tab</code> default table, nor is the root directory applied to the filename supplied to the <code>-t</code> option.</p>
	<code>-t table-file</code>	<p>Set the table file used by <code>devlinks</code> to specify the links that must be created. If this option is not given, <code>/etc/devlink.tab</code> is used. This option gives a way to instruct <code>devlinks</code> just to perform a particular piece of work, since just the links-types that <code>devlinks</code> is supposed to create can be specified in a command-file and fed to <code>devlinks</code>.</p>
ERRORS		<p>If <code>devlinks</code> finds an error in a line of the <i>table-file</i> it prints a warning message on its standard output and goes on to the next line in the <i>table-file</i> without performing any of the actions specified by the erroneous rule.</p> <p>If it cannot create a link for some filesystem-related reason it prints an error-message and continues with the current rule.</p> <p>If it cannot read necessary data it prints an error message and continues with the next <i>table-file</i> line.</p>

EXAMPLES **EXAMPLE 1** Examples of `/etc/devlink.tab` fields

Example `/etc/devlink.tab` fields are:

```
type=pseudo;name=win    win\M0
type=ddi_display    framebuffer/\M0    fb\N0
```

The first example states that all devices of type `pseudo` with a name component of `win` will be linked to `/dev/winx`, where `x` is the minor-component of the *devinfo-name* (this is always a single-digit number for the `win` driver).

The second example states that all *devinfo* nodes of type `ddi_display` will be linked to entries under the `/dev/framebuffer` directory, with names identical to the entire minor component of the `/devices` name. In addition an extra link will be created pointing from `/dev/fbn` to the entry under `/dev/framebuffer`. This entry will use a counter to end the name.

FILES	<code>/dev</code>	entries for the miscellaneous devices for general use
	<code>/devices</code>	device nodes
	<code>/etc/devlink.tab</code>	the default rule-file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

BUGS It is very easy to construct mutually-contradictory link specifications, or specifications that can never be matched. The program does not check for these conditions.

devnm(1M)

NAME devnm – device name

SYNOPSIS /usr/sbin/devnm *name* [*name...*]

DESCRIPTION The devnm command identifies the special file associated with the mounted file system where the argument *name* resides. One or more *name* can be specified.

EXAMPLES The command:

```
/usr/sbin/devnm /usr
```

produces:

```
/dev/dsk/c0t3d0s6 /usr
```

if /usr is mounted on /dev/dsk/c0t3d0s6.

FILES /dev/dsk/*
/etc/mnttab

NAME	devreserv – reserve devices for exclusive use
SYNOPSIS	devreserv [<i>key</i> [<i>device-list...</i>]]
DESCRIPTION	<p>devreserv reserves devices for exclusive use. When the device is no longer required, use devfree to release it.</p> <p>devreserv reserves at most one device per <i>device-list</i>. Each list is searched in linear order until the first available device is found. If a device cannot be reserved from each list, the entire reservation fails.</p> <p>When devreserv is invoked without arguments, it lists the devices that are currently reserved and shows to which key it was reserved. When devreserv is invoked with only the <i>key</i> argument, it lists the devices that are currently reserved to that key.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>key</i> Designates a unique key on which the device will be reserved. The key must be a positive integer.</p> <p><i>device-list</i> Defines a list of devices that devreserv will search to find an available device. The list must be formatted as a single argument to the shell.</p>
EXAMPLES	<p>EXAMPLE 1 Reserving a floppy disk and a cartridge tape.</p> <p>This example reserves a floppy disk and a cartridge tape:</p> <pre>\$ key=\$\$ \$ echo "The current Process ID is equal to: \$key" The Current Process ID is equal to: 10658 \$ devreserv \$key diskette1 ctape1</pre> <p>EXAMPLE 2 Listing all devices currently reserved.</p> <p>This example lists all devices currently reserved:</p> <pre>\$ devreserv disk1 2423 diskette1 10658 ctape1 10658</pre> <p>EXAMPLE 3 Listing all devices currently reserved to a particular key.</p> <p>This example lists all devices currently reserved to a particular key:</p> <pre>\$ devreserv \$key diskette1 ctape1</pre>
EXIT STATUS	The following exit values are returned:

devreserv(1M)

- 0 Successful completion.
- 1 Command syntax was incorrect, an invalid was option used, or an internal error occurred.
- 2 Device table or device reservation table could not be opened for reading.
- 3 Device reservation request could not be fulfilled.

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `devfree(1M)`, `attributes(5)`

NOTES The commands `devreserv` and `devfree` are used to manage the availability of devices on a system. Their use is on a participatory basis and they do not place any constraints on the actual access to the device. They serve as a centralized bookkeeping point for those who wish to use them. Devices which have been reserved cannot be used by processes which utilize the device reservation functions until the reservation has been canceled. However, processes that do not use device reservation may use a device that has been reserved since such a process would not have checked for its reservation status.

NAME	df – displays number of free disk blocks and files
SYNOPSIS	<pre> /usr/bin/df [-F <i>FSType</i>] [-abeghHklnPtV] [-o <i>FSType-specific_options</i>] [<i>block_device</i> <i>directory</i> <i>file</i> <i>resource</i> ...] /usr/xpg4/bin/df [-F <i>FSType</i>] [-abeghHklnPtV] [-o <i>FSType-specific_options</i>] [<i>block_device</i> <i>directory</i> <i>file</i> <i>resource</i> ...] </pre>
DESCRIPTION	<p>The <code>df</code> command displays the amount of disk space occupied by mounted or unmounted file systems, the amount of used and available space, and how much of the file system's total capacity has been used. The file system is specified by device, or by referring to a file or directory on the specified file system.</p> <p>Used without operands or options, <code>df</code> reports on all mounted file systems.</p> <p><code>df</code> may not be supported for all <i>FSTypes</i>.</p> <p>If <code>df</code> is run on a networked mount point that the automounter has not yet mounted, the file system size will be reported as zero. As soon as the automounter mounts the file system, the sizes will be reported correctly.</p>
OPTIONS	<p>The following options are supported for both <code>/usr/bin/df</code> and <code>/usr/xpg4/bin/df</code>:</p> <ul style="list-style-type: none"> -a Report on all file systems including ones whose entries in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>) have the <code>ignore</code> option set. -b Print the total number of kilobytes free. -e Print only the number of files free. -F <i>FSType</i> Specify the <i>FSType</i> on which to operate. The <code>-F</code> option is intended for use with unmounted file systems. The <i>FSType</i> should be specified here or be determinable from <code>/etc/vfstab</code> (see <code>vfstab(4)</code>) have the <code>by</code> matching the <i>directory</i>, <i>block_device</i>, or <i>resource</i> with an entry in the table, or by consulting <code>/etc/default/fs</code>. See <code>default_fs(4)</code>. -g Print the entire <code>statvfs(2)</code> structure. This option is used only for mounted file systems. It can not be used with the <code>-o</code> option. This option overrides the <code>-b</code>, <code>-e</code>, <code>-k</code>, <code>-n</code>, <code>-P</code>, and <code>-t</code> options. -h Like <code>-k</code>, except that sizes are in a more human readable format. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of

df(1M)

	normally available space that is currently allocated to all files on the file system. All sizes are scaled to a human readable format, for example, 14K, 234M, 2.7G, or 3.0T. Scaling is done by repetitively dividing by 1024.
	This option overrides the <code>-b</code> , <code>-e</code> , <code>-g</code> , <code>-k</code> , <code>-n</code> , <code>-t</code> , and <code>-V</code> options. This option only works on mounted filesystems and can not be used together with <code>-o</code> option.
<code>-H</code>	This option is the same as <code>-h</code> , but scaling is done by dividing by 1000 instead of 1024.
<code>-k</code>	Print the allocation in kbytes. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of normally available space that is currently allocated to all files on the file system. This option overrides the <code>-b</code> , <code>-e</code> , <code>-n</code> , and <code>-t</code> options.
<code>-l</code>	Report on local file systems only. This option is used only for mounted file systems. It can not be used with the <code>-o</code> option.
<code>-n</code>	Print only the <i>FSType</i> name. Invoked with no operands, this option prints a list of mounted file system types. This option is used only for mounted file systems. It can not be used with the <code>-o</code> option.
<code>-o FSType-specific_options</code>	Specify <i>FSType-specific</i> options. These options are comma-separated, with no intervening spaces. See the manual page for the <i>FSType-specific</i> command for details.
<code>-t</code>	Print full listings with totals. This option overrides the <code>-b</code> , <code>-e</code> , and <code>-n</code> options.
<code>-V</code>	Echo the complete set of file system specific command lines, but do not execute them. The command line is generated by using the options and operands provided by the user and adding to them information derived from <code>/etc/mnttab</code> , <code>/etc/vfstab</code> , or <code>/etc/default/fs</code> . This option may be used to verify and validate the command line.

/usr/xpg4/bin/df | The following option is supported for `/usr/xpg4/bin/df` only:

	-P	Same as -k except in 512-byte units.
OPERANDS	df interprets operands according to the following precedence: <i>block_device</i> , <i>directory</i> , <i>file</i> . The following operands are supported:	
	<i>block_device</i>	represents a block special device (for example, <code>/dev/dsk/c1d0s7</code>); the corresponding file system need not be mounted.
	<i>directory</i>	represents a valid directory name. df reports on the file system that contains <i>directory</i> .
	<i>file</i>	represents a valid file name. df reports on the file system that contains <i>file</i> .
	<i>resource</i>	represents an NFS resource name.
USAGE	See <code>largefile(5)</code> for the description of the behavior of df when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).	
EXAMPLES	<p>EXAMPLE 1 Writing Portable Information About the /usr File System</p> <p>The following example writes portable information about the /usr file system:</p> <pre>example% /usr/xpg4/bin/df -P /usr</pre> <p>EXAMPLE 2 Writing Portable Information About the /usr File System</p> <p>Assuming that /usr/src is part of the /usr file system, the following example writes portable information :</p> <pre>example% /usr/xpg4/bin/df -P /usr/src</pre> <p>EXAMPLE 3 Using df to Display Inode Usage</p> <p>The following example displays inode usage on all ufs file systems:</p> <pre>example% /usr/bin/df -F ufs -o i</pre>	
ENVIRONMENT VARIABLES	SYSV3	This variable is used to override the default behavior of df and provide compatibility with INTERACTIVE UNIX System and SCO UNIX installation scripts. As the SYSV3 variable is provided for compatibility purposes only, it should not be used in new scripts.
	When set, any header which normally displays "files" will now display "nodes". See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of df: LC_CTYPE, LC_MESSAGES, and NLSPATH.	
EXIT STATUS	The following exit values are returned:	
	0	Successful completion.

df(1M)

>0 An error occurred.

FILES /dev/dsk/* disk devices
/etc/default/fs default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs, where LOCAL is the default partition for a command if no FSType is specified.
/etc/mnttab mount table
/etc/vfstab list of default parameters for each file system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

/usr/bin/df

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

/usr/xpg4/bin/df

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4

NOTES If UFS logging is enabled on a file system, the disk space used for the log is reflected in the `df` report. The log is allocated from free blocks on the file system, and it is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 64 Mbytes.

NAME	dfmounts – display mounted resource information								
SYNOPSIS	dfmounts [-F <i>FSType</i>] [-h] [-o <i>specific_options</i>] [<i>restriction...</i>]								
DESCRIPTION	<p>dfmounts shows the local resources shared through a distributed file system <i>FSType</i> along with a list of clients that have the resource mounted. If <i>restriction</i> is not specified, dfmounts shows file systems that are currently shared on any NFS server. <i>specific_options</i> as well as the availability and semantics of <i>restriction</i> are specific to particular distributed file system types.</p> <p>If dfmounts is entered without arguments, all remote resources currently mounted on the local system are displayed, regardless of file system type.</p>								
dfmounts Output	<p>The output of dfmounts consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:</p> <p><i>resource server pathname clients ...where:</i></p> <table border="0" style="margin-left: 2em;"> <tr> <td style="padding-right: 1em;"><i>resource</i></td> <td>Specifies the resource name that must be given to the mount(1M) command.</td> </tr> <tr> <td><i>server</i></td> <td>Specifies the system from which the resource was mounted.</td> </tr> <tr> <td><i>pathname</i></td> <td>Specifies the pathname that must be given to the share(1M) command.</td> </tr> <tr> <td><i>clients</i></td> <td>Is a comma-separated list of systems that have mounted the resource. Clients are listed in the form <i>domain.</i>, <i>domain.system</i>, or <i>system</i>, depending on the file system type.</td> </tr> </table> <p>A field may be null. Each null field is indicated by a hyphen (-) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.</p> <p>Fields with whitespace are enclosed in quotation marks (" ").</p>	<i>resource</i>	Specifies the resource name that must be given to the mount(1M) command.	<i>server</i>	Specifies the system from which the resource was mounted.	<i>pathname</i>	Specifies the pathname that must be given to the share(1M) command.	<i>clients</i>	Is a comma-separated list of systems that have mounted the resource. Clients are listed in the form <i>domain.</i> , <i>domain.system</i> , or <i>system</i> , depending on the file system type.
<i>resource</i>	Specifies the resource name that must be given to the mount(1M) command.								
<i>server</i>	Specifies the system from which the resource was mounted.								
<i>pathname</i>	Specifies the pathname that must be given to the share(1M) command.								
<i>clients</i>	Is a comma-separated list of systems that have mounted the resource. Clients are listed in the form <i>domain.</i> , <i>domain.system</i> , or <i>system</i> , depending on the file system type.								
OPTIONS	<table border="0" style="margin-left: 2em;"> <tr> <td style="padding-right: 1em;">-F <i>FSType</i></td> <td>Specify filesystem type. Defaults to the first entry in <i>/etc/dfs/fstypes</i>. dfshares(1M)

NAME dfshares – list available resources from remote or local systems

SYNOPSIS **dfshares** [-F *FSType*] [-h] [-o *specific_options*] [*server...*]

DESCRIPTION *dfshares* provides information about resources available to the host through a distributed file system of type *FSType*. *specific_options* as well as the semantics of *server* are specific to particular distributed file systems.

If *dfshares* is entered without arguments, all resources currently shared on the local system are displayed, regardless of file system type.

The output of *dfshares* consists of an optional header line (suppressed with the *-h* flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server access transport

where

resource Specifies the resource name that must be given to the *mount(1M)* command.

server Specifies the name of the system that is making the resource available.

access Specifies the access permissions granted to the client systems, either *ro* (for read-only) or *rw* (for read/write). If *dfshares* cannot determine access permissions, a hyphen (-) is displayed.

transport Specifies the transport provider over which the resource is shared.

A field may be null. Each null field is indicated by a hyphen (-) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.

OPTIONS

-F *FSType* Specify filesystem type. Defaults to the first entry in */etc/dfs/fstypes*.

-h Suppress header line in output.

-o *specific_options* Specify options specific to the filesystem provided by the -F option.

FILES */etc/dfs/fstypes*

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfscu

SEE ALSO `mount(1M)`, `share(1M)`, `unshare(1M)`, `attributes(5)`

NAME	df_ufs – report free disk space on ufs file systems				
SYNOPSIS	df -F ufs [<i>generic_options</i>] [-o i] [<i>directory</i> <i>special</i>]				
DESCRIPTION	df displays the amount of disk space occupied by ufs file systems, the amount of used and available space, and how much of the file system’s total capacity has been used. The amount of space reported as used and available is less than the amount of space in the file system; this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this may be adjusted using tuneufs(1M). When all the space on the file system except for this reserve is in use, only the superuser can allocate new files and data blocks to existing files. When the file system is overallocated in this way, df may report that the file system is more than 100% utilized. If neither <i>directory</i> nor <i>special</i> is specified, df displays information for all mounted ufs file systems.				
OPTIONS	The following options are supported: <i>generic_options</i> Options supported by the generic df command. See df(1M) for a description of these options. -o Specify ufs file system specific options. The available option is: i Report the number of used and free inodes. This option may not be used with <i>generic_options</i> .				
FILES	/etc/mnttab list of file systems currently mounted				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu, SUNWxcu4</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu, SUNWxcu4
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu, SUNWxcu4				
SEE ALSO	df(1M), tuneufs(1M), fs_ufs(4), mnttab(4), attributes(5)				
NOTES	df calculates its results differently for mounted and unmounted file systems. For unmounted systems, the numbers reflect the 10% reservation mentioned above; this reservation is not reflected in df output for mounted file systems. For this reason, the available space reported by the generic command may differ from the available space reported by this module.				

dhcpcagent(1M)

NAME	<code>dhcpcagent</code> – Dynamic Host Configuration Protocol (DHCP) client daemon
SYNOPSIS	<code>dhcpcagent</code> [-a] [-d n] [-f] [-v]
DESCRIPTION	<p><code>dhcpcagent</code> implements the client half of the Dynamic Host Configuration Protocol (DHCP) for machines running Solaris software.</p> <p>The <code>dhcpcagent</code> daemon obtains configuration parameters for the client (local) machine's network interfaces from a DHCP server. These parameters may include a lease on an IP address, which gives the client machine use of the address for the period of the lease, which may be infinite. If the client wishes to use the IP address for a period longer than the lease, it must negotiate an extension using DHCP. For this reason, <code>dhcpcagent</code> must run as a daemon, terminating only when the client machine powers down.</p> <p>The <code>dhcpcagent</code> daemon is controlled through <code>ifconfig(1M)</code> in much the same way that the <code>init(1M)</code> daemon is controlled by <code>telinit(1M)</code>. <code>dhcpcagent</code> may be invoked as a user process, albeit one requiring root privileges, but this is not necessary, as <code>ifconfig(1M)</code> will start it automatically.</p> <p>When invoked, <code>dhcpcagent</code> enters a passive state while it awaits instructions from <code>ifconfig(1M)</code>. When it receives a command to configure an interface, it starts DHCP. Once DHCP is complete, <code>dhcpcagent</code> may be queried for the values of the various network parameters. In addition, if DHCP was used to obtain a lease on an address for an interface, the interface is configured and brought up. When a lease is obtained, it is automatically renewed as necessary. If the lease cannot be renewed, <code>dhcpcagent</code> will take the interface down at the end of the lease. If the configured interface is found to have a different IP address, subnet mask or broadcast address from those obtained from DHCP, the interface is abandoned from DHCP control.</p> <p>In addition to DHCP, <code>dhcpcagent</code> also supports BOOTP. See <i>RFC 951, Bootstrap Protocol</i>. Configuration parameters obtained from a BOOTP server are treated identically to those received from a DHCP server, except that the IP address received from a BOOTP server always has an infinite lease.</p> <p>DHCP also acts as a mechanism to configure other information needed by the client, for example, the domain name and addresses of routers. Aside from the IP address, netmask, broadcast address and default router, the agent does not directly configure the workstation, but instead acts as a database which may be interrogated by other programs, and in particular by <code>dhcpcinfo(1)</code>.</p> <p>On clients with a single interface, this is quite straightforward. Clients with multiple interfaces may present difficulties, as it is possible that some information arriving on different interfaces may need to be merged, or may be inconsistent. Furthermore, the configuration of the interfaces is asynchronous, so requests may arrive while some or all of the interfaces are still unconfigured. To handle these cases, one interface may be designated as primary, which makes it the authoritative source for the values of DHCP parameters in the case where no specific interface is requested. See <code>dhcpcinfo(1)</code> and <code>ifconfig(1M)</code> for details.</p>

The `dhcpcagent` daemon can be configured to request a particular host name. See the `REQUEST_HOSTNAME` description in the `FILES` section. When first configuring a client to request a host name, you must perform the following steps as root to ensure that the full DHCP negotiation takes place:

```
# pkill dhcpcagent
# rm /etc/dhcp/interface.dhc
# reboot
```

Messages

The `dhcpcagent` daemon writes information and error messages in five categories:

- critical** Critical messages indicate severe conditions that prevent proper operation.
- errors** Error messages are important, sometimes unrecoverable events due to resource exhaustion and other unexpected failure of system calls; ignoring errors may lead to degraded functionality.
- warnings** Warnings indicate less severe problems, and in most cases, describe unusual or incorrect datagrams received from servers, or requests for service that cannot be provided.
- informational** Informational messages provide key pieces of information that can be useful to debugging a DHCP configuration at a site. Informational messages are generally controlled by the `-v` option. However, certain critical pieces of information, such as the IP address obtained, are always provided.
- debug** Debugging messages, which may be generated at two different levels of verbosity, are chiefly of benefit to persons having access to source code, but may be useful as well in debugging difficult DHCP configuration problems. Debugging messages are only generated when using the `-d` option.

When `dhcpcagent` is run without the `-f` option, all messages are sent to the system logger `syslog(3C)` at the appropriate matching priority and with a facility identifier `LOG_DAEMON`. When `dhcpcagent` is run with the `-f` option, all messages are directed to standard error.

OPTIONS

The following options are supported:

- a** Adopt a configured interface. This option is for use with diskless DHCP clients. In the case of diskless DHCP, DHCP has already been performed on the network interface providing the operating system image prior to running `dhcpcagent`. This option instructs the agent to take over control of the interface. It is intended primarily for use in boot scripts.
- d *n*** Set debug level to *n*. Two levels of debugging are currently available, 1 and 2; the latter is more verbose.
- f** Run in the foreground instead of as a daemon process. When this option is used, messages are sent to standard error instead of to `syslog(3C)`.

dhcpageant(1M)

-v Provide verbose output useful for debugging site configuration problems.

FILES

/etc/dhcp/if.dhc

Contains the configuration for interface. The mere existence of this file does not imply that the configuration is correct, since the lease may have expired.

/etc/default/dhcpageant

Contains default values for tunable parameters. All values may be qualified with the interface they apply to by prepending the interface name and a period (".") to the interface parameter name. The parameters include:

RELEASE_ON_SIGTERM

Indicates that a RELEASE rather than a DROP should be performed on managed interfaces when the agent terminates.

OFFER_WAIT

Indicates how long to wait between checking for valid OFFERS after sending a DISCOVER.

ARP_WAIT

Indicates how long to wait for clients to respond to an ARP request before concluding the address in the ARP request is unused.

IGNORE_FAILED_ARP

Specifies whether or not the agent should assume an address is available, in the unlikely event that ARP cannot be performed on that address.

CLIENT_ID

Indicates the value that should be used to uniquely identify the client to the server.

PARAM_REQUEST_LIST

Specifies a list of comma-separated integer values of options for which the client would like values.

REQUEST_HOSTNAME

Indicates the client requests the DHCP server to map the client's leased IP address to the host name associated with the network interface that performs DHCP on the client. The host name must be specified in the /etc/hostname.*interface* file for the relevant interface on a line of the form

inet hostname

where *hostname* is the host name requested.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NOTES | Currently, configurations where more than one interface is attached to the same physical network are unsupported. This precludes use of virtual interfaces.

dhcpconfig(1M)

NAME dhcpconfig – DHCP service configuration utility

SYNOPSIS

```

dhcpconfig -D -r resource -p path [-u uninterpreted] [-l lease_length] [-n ]
    [-d DNS_domain] [-a DNS_server_addresses] [-h hosts_resource]
    [-y hosts_domain]

dhcpconfig -R server_addresses

dhcpconfig -U [-f] [-x] [-h]

dhcpconfig -N network_address [-m subnet_mask] [-b ] [-t router_addresses]
    [-y NIS-domain] [-a NIS_server_addresses]

dhcpconfig -C -r resource -p path [-f] [-k] [-u uninterpreted]

dhcpconfig -X filename [-m macro_list] [-o option_list] [-a network_addresses]
    [-f] [-x]

dhcpconfig -I filename [-f]

```

DESCRIPTION The `dhcpconfig` command is used to configure and manage the Dynamic Host Configuration Protocol (DHCP) service or BOOTP relay services. It is intended for use by experienced Solaris system administrators and is designed for ease of use in scripts. The `dhcprmgr` utility is recommended for less experienced administrators or those preferring a graphical utility to configure and manage the DHCP service or BOOTP relay service.

The `dhcpconfig` command can be run by root, or by other users assigned to the DHCP Management profile. See `rbac(5)` and `user_attr(4)`.

`dhcpconfig` requires one of the following function flags: `-D`, `-R`, `-U`, `-N`, `-C`, `-X`, or `-I`.

The `dcpconfig` menu driven mode is supported in Solaris 8 and previous versions of Solaris.

Where dhcpconfig Obtains Configuration Information

`dhcpconfig` scans various configuration files on your Solaris machine for information it can use to assign values to options contained in macros it adds to the `dhcptab` configuration table. The following table lists information `dhcpconfig` needs, the source used, and how the information is used:

<i>Information</i>	<i>Source</i>	<i>Where Used</i>
Timezone	System date, timezone settings	Locale macro
DNS parameters	<code>nsswitch.conf</code> , <code>/etc/resolv.conf</code>	Server macro
NIS parameters	System domainname, <code>nsswitch.conf</code> , NIS	Network macros

Subnetmask	Network interface, <code>netmasks</code> table in <code>nameservice</code>	Network macros
------------	--	----------------

If you have not set these parameters on your server machine, you should do so before configuring the DHCP server with `dhcpconfig`. Note that if you specify options with the `dhcpconfig -D` command line, the values you supply override the values obtained from the system files.

OPTIONS The following options are supported:

- C Convert to using a new data store, recreating the DHCP data tables in a format appropriate to the new data store, and setting up the DHCP server to use the new data store.
 The following sub-options are required:
 - p *path_to_data* The paths for `SUNWfiles` and `SUNWbinfiles` must be absolute UNIX pathnames. The path for `SUNWnisplus` must be a fully specified NIS+ directory (including the trailing period.) See `dhcp_modules(5)`.
 - r *data_resource* New data store resource. One of the following must be specified: `SUNWfiles`, `SUNWbinfiles`, or `SUNWnisplus`. See `dhcp_modules(5)`.
 The following sub-options are optional:
 - f Do not prompt for confirmation. If `-f` is not used, a warning and confirmation prompt are issued before the conversion starts.
 - k Keep the old DHCP data tables after successful conversion. If any problem occurs during conversion, tables will not be deleted even if `-k` sub-option is not specified.
 - u *uninterpreted* Data which will be ignored by `dhcpconfig`, but passed on to the datastore for interpretation. This might be used for a database account name or other authentication or authorization

parameters required by a particular data store. The `-u` sub-option is not used with the `SUNWfiles`, `SUNWbinfiles`, and `SUNWnisplus` data stores. See `dhcp_modules(5)`.

-D

Configure the DHCP service.

The following sub-options are required:

`-r data_resource`

One of the following must be specified: `SUNWfiles`, `SUNWbinfiles`, or `SUNWnisplus`. Other data stores may be available. See `dhcp_modules(5)`.

`-p path`

The paths for `SUNWfiles` and `SUNWbinfiles` must be absolute UNIX pathnames. The path for `SUNWnisplus` must be a fully specified NIS+ directory (including the trailing period.) . See `dhcp_modules(5)`.

The following sub-options are optional:

`-a DNS_servers`

IP addresses of DNS servers, separated with commas.

`-d DNS_domain`

DNS domain name.

`-h hosts_resource`

Resource in which to place hosts data. Usually, the name service in use on the server. Valid values are `nisplus`, `files`, or `dns`.

`-l seconds`

Lease length used for addresses not having a specified lease length, in seconds.

`-n`

Non-negotiable leases

`-y hosts_domain`

DNS or NIS+ domain name to be used for hosts data. Valid only if `dns` or `nisplus` is specified for `-h` sub-option.

`-u uninterpreted`

Data which will be ignored by `dhcpconfig`, but passed on to the datastore for interpretation. This

might be used for a database account name or other authentication or authorization parameters required by a particular data store. The `-u` sub-option is not used with the `SUNWfiles`, `SUNWbinfiles`, and `SUNWnisplus` data stores. See `dhcp_modules(5)`.

`-I filename`

Import data from *filename*, containing data previously exported from a Solaris DHCP server. Note that after importing, you may have to edit macros to specify the correct domain names, and edit network tables to change the owning server of addresses in imported networks. Use `dhtadm` and `pntadm` to do this.

The following sub-option is supported:

`-f` Replace any conflicting data with the data being imported.

`-N net_address`

Configure an additional network for DHCP service.

The following sub-options are supported:

`-a NIS_server_addresses` List of IP addresses of NIS servers.

`-b` Network is a point-to-point (PPP) network, therefore no broadcast address should be configured. If `-b` is not used, the network is assumed to be a LAN, and the broadcast address is determined using the network address and subnet mask.

`-m xxx.xxx.xxx.xxx` Subnet mask for the network; if `-m` is not used, subnet mask is obtained from netmasks.

`-t router_addresses` List of router IP addresses; if not specified, router discovery flag will be set.

`-y NIS_domain_name` If NIS is used on this network, specify the NIS domain name.

`-R server_addresses`

Configure the BOOTP relay service. BOOTP or DHCP requests are forwarded to the list of servers specified.

dhcpconfig(1M)

- U Unconfigure the DHCP service or BOOTP relay service.
- The following sub-options are supported:
- f Do not prompt for confirmation. If -f is not used, a warning and confirmation prompt is issued.
 - h Delete hosts entries from name service.
 - x Delete the `dhcptab` and network tables.
- x *filename* Export data from the DHCP data tables, saving to *filename*, to move the data to another Solaris DHCP server.
- The following sub-options are optional:
- a *networks_to_export* List of networks whose addresses should be exported, or the keyword ALL to specify all networks. If -a is not specified, no networks are exported.
 - m *macros_to_export* List of macros to export, or the keyword ALL to specify all macros. If -m is not specified, no macros are exported.
 - o *options_to_export* List of options to export, or the keyword ALL to specify all options. If -o is not specified, no options are exported.
 - x Delete the data from this server after it is exported. If -x is not specified you are in effect copying the data.

EXAMPLES

EXAMPLE 1 Configuring DHCP Service with Binary Files Data Store

The following command configures DHCP service, using the binary files data store, in the DNS domain `acme.eng`, with a lease time of 28800 seconds (8 hours),

```
example# dhcpconfig -D -r SUNWbinfiles -p /var/dhcp -l 28800 -d acme.eng  
-a 120.30.33.4 -h dns -y acme.eng
```

EXAMPLE 2 Configuring BOOTP Relay Agent

The following command configures the DHCP daemon as a BOOTP relay agent, which will forward BOOTP and DHCP requests to the servers having the IP addresses 120.30.33.7 and 120.30.42.132:

```
example# dhcpconfig -R 120.30.33.7,120.30.42.132
```

EXAMPLE 3 Unconfiguring DHCP Service

The following command unconfigures the DHCP service, with confirmation, and deletes the DHCP data tables and host table entries:

```
example# dhcpconfig -U -x -h
```

EXAMPLE 4 Configuring a Network for DHCP Service

The following command configures an additional LAN network for DHCP service, specifying that clients should use router discovery and providing the NIS domain name and NIS server address:

```
example# dhcpconfig -N 120.30.171.0 -y east.acme.eng.com -a 120.30.33.4
```

EXAMPLE 5 Converting to SUNWnisplus Data Store

The following command converts a DHCP server from using a text or binary files data store to a NIS+ data store, deleting the old data store's DHCP tables:

```
example# dhcpconfig -C -r SUNWnisplus -p whatever.com.
```

EXAMPLE 6 Exporting a Network, Macros, and Options from a DHCP Server

The following command exports one network (120.30.171.0) and its addresses, the macro 120.30.171.0, and the options motd and PSptr from a DHCP server, saves the exported data in file /export/var/120301710_data, and deletes the exported data from the server.

```
example# dhcpconfig -X /var/dhcp/120301710_export
-a 120.30.171.0 -m 120.30.171.0 -o motd,PSptr
```

EXAMPLE 7 Importing Data on a DHCP Server

The following command imports DHCP data from a file, /net/golduck/export/var/120301710_data, containing data previously exported from a Solaris DHCP server, and overwrites any conflicting data on the importing server:

```
example# dhcpconfig -I /net/golduck/export/var/120301710_data -f
```

dhcpconfig(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

System Administration Guide: IP Services

NAME dhcpcmgr – graphical interface for managing DHCP service

SYNOPSIS `/usr/sadm/admin/bin/dhcpcmgr`

DESCRIPTION dhcpcmgr is a graphical user interface which enables you to manage the Dynamic Host Configuration Protocol (DHCP) service on the local system. It performs the functions of the `dhcpcconfig`, `dhtadm`, and `pntadm` command line utilities. You must be `root` to use `dhcpcmgr`. The `dhcpcmgr Help`, available from the `Help` menu, contains detailed information about using the tool.

USAGE You can perform the following tasks using `dhcpcmgr`:

- Configure DHCP service
Use `dhcpcmgr` to configure the DHCP daemon as a DHCP server, and select the data store to use for storing network configuration tables..
- Configure BOOTP relay service
Use `dhcpcmgr` to configure the DHCP daemon as a BOOTP relay.
- Manage DHCP or BOOTP relay service
Use `dhcpcmgr` to start, stop, enable, disable or unconfigure the DHCP service or BOOTP relay service, or change DHCP server parameters.
- Manage DHCP addresses
Use `dhcpcmgr` to add, modify, or delete IP addresses leased by the DHCP service.
- Manage DHCP macros
Use `dhcpcmgr` to add, modify or delete macros used to supply configuration parameters to DHCP clients.
- Manage DHCP options
Use `dhcpcmgr` to add, modify or delete options used to define parameters deliverable through DHCP.
- Convert to a new DHCP data store
Use `dhcpcmgr` to configure the DHCP server to use a different data store, and convert the DHCP data to the format used by the new data store.
- Move DHCP data to another server
Use `dhcpcmgr` to export data from one Solaris DHCP server and import data onto another Solaris DHCP server.

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

Solaris DHCP Service Developer's Guide

System Administration Guide: IP Services

NAME	dhtadm – DHCP configuration table management utility		
SYNOPSIS	<pre> dhtadm -C [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -A -s <i>symbol_name</i> -d <i>definition</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -A -m <i>macro_name</i> -d <i>definition</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -M -s <i>symbol_name</i> -d <i>definition</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -M -s <i>symbol_name</i> -n <i>new_name</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -M -m <i>macro_name</i> -n <i>new_name</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -M -m <i>macro_name</i> -d <i>definition</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -M -m <i>macro_name</i> -e <i>symbol=value</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -D -s <i>symbol_name</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -D -m <i>macro_name</i> [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -P [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -R [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] dhtadm -B [-v] [<i>batchfile</i>] </pre>		
DESCRIPTION	<p>dhtadm manages the Dynamic Host Configuration Protocol (DHCP) service configuration table, <code>dhcptab</code>. You can use it to add, delete, or modify DHCP configuration macros or options or view the table. For a description of the table format, see <code>dhcptab(4)</code>.</p> <p>The <code>dhtadm</code> command can be run by root, or by other users assigned to the DHCP Management profile. See <code>rbac(5)</code> and <code>user_attr(4)</code>.</p> <p>After you make changes with <code>dhtadm</code>, you should issue a <code>SIGHUP</code> to the DHCP server, causing it to read the <code>dhcptab</code> and pick up the changes. Do this using the command using the <code>kill -HUP in.dhcpd</code> command. See <code>in.dhcpd(1M)</code>.</p>		
OPTIONS	<p>One of the following function flags must be specified with the <code>dhtadm</code> command: <code>-A</code>, <code>-B</code>, <code>-C</code>, <code>-D</code>, <code>-M</code>, <code>-P</code> or <code>-R</code>.</p> <p>The following options are supported:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>-A</code></td> <td>Add a symbol or macro definition to the <code>dhcptab</code> table.</td> </tr> </table>	<code>-A</code>	Add a symbol or macro definition to the <code>dhcptab</code> table.
<code>-A</code>	Add a symbol or macro definition to the <code>dhcptab</code> table.		

	<p>The following sub-options are required:</p> <p>-d <i>definition</i> Specify a macro or symbol definition.</p> <p><i>definition</i> must be enclosed in single quotation marks. For macros, use the form -d 'symbol=value:symbol=value:'. For symbols, the definition is a series of fields that define a symbol's characteristics. The fields are separated by commas. Use the form -d 'context,code,type,granularity,maximum'. See <code>dhcptab(4)</code> for information about these fields.</p> <p>-m <i>macro_name</i> Specify the name of the macro to be added.</p> <p>The -d option must be used with the -m option. The -s option cannot be used with the -m option.</p> <p>-s <i>symbol_name</i> Specify the name of the symbol to be added.</p> <p>The -d option must be used with the -s option. The -m option cannot be used with the -s option.</p>
-B	<p>Batch process <code>dhtadm</code> commands. <code>dhtadm</code> will read from the specified file or from standard input a series of <code>dhtadm</code> commands and execute them within the same process. Processing many <code>dhtadm</code> commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using <code>dhtadm</code> in scripts.</p> <p>The following sub-option is optional:</p> <p>-v Display commands to standard output as they are processed.</p>
-C	Create the DHCP service configuration table, <code>dhcptab</code> .
-D	Delete a symbol or macro definition.
	<p>The following sub-options are required:</p> <p>-m <i>macro_name</i> Delete the specified macro.</p> <p>-s <i>symbol_name</i> Delete the specified symbol.</p>
-M	Modify an existing symbol or macro definition.

The following sub-options are required:

-d *definition*

Specify a macro or symbol definition to modify.

The definition must be enclosed in single quotation marks. For macros, use the form `-d`

`'symbol=value:symbol=value:'`. For symbols, the definition is a series of fields that define a symbol's characteristics. The fields are separated by commas.

Use the form `-d`

`'context,code,type,granularity,maximum'`. See `dhcptab(4)` for information about these fields.

-e

This sub-option uses the `symbol=value` argument.

Use it to edit a `symbol/value` pair within a macro. To add a symbol which does not have an associate value, enter:

`symbol=NULL_VALUE` To delete a symbol definition from a macro, enter:

`symbol=`

-m

This sub-option uses the `macro_name` argument. The `-n`, `-d`, or `-e` sub-options are legal companions for this sub-option..

-n

This sub-option uses the `new_name` argument and modifies the name of the object specified by the `-m` or `-s` sub-option. It is not limited to macros. Use it to specify a new macro name or symbol name.

-s

This sub-option uses the `symbol_name` argument. Use it to specify a symbol. The `-d` sub-option is a legal companion.

-p *path*

Override the `dhcpsvc.conf(4)` configuration value for `PATH=` with *path*. See `dhcpsvc.conf(4)` for more details regarding *path*. See `dhcp_modules(5)` for information regarding data storage modules for the DHCP service.

-P

Print (display) the `dhcptab` table.

-r *data_store_resource*

Override the `dhcpsvc.conf(4)` configuration value for `RESOURCE=` with the *data_store_resource* specified.

dhtadm(1M)

	See <code>dhcpsvc.conf(4)</code> for more details on resource type. See <i>Solaris DHCP Service Developer's Guide</i> for more information about adding support for other data stores. See <code>dhcp_modules(5)</code> for information regarding data storage modules for the DHCP service.
<code>-R</code>	Remove the <code>dhcptab</code> table.
<code>-u</code> <i>uninterpreted</i>	Data which will be ignored by <code>dhtadm</code> , but passed to currently configured public module, to be interpreted by the data store. This might be used for a database account name or other authentication or authorization parameters required by a particular data store. Uninterpreted data is stored within <code>RESOURCE_CONFIG</code> keyword of <code>dhcpsvc.conf(4)</code> . See <code>dhcp_modules(5)</code> for information regarding data storage modules for the DHCP service.

EXAMPLES

EXAMPLE 1 Creating the DHCP Service Configuration Table

The following command creates the DHCP service configuration table, `dhcptab`:

```
# dhtadm -C
```

EXAMPLE 2 Adding a Symbol Definition

The following command adds a Vendor option symbol definition for a new symbol called `MySym` to the `dhcptab` table in the `SUNWfiles` resource in the `/var/mydhcp` directory:

```
# dhtadm -A -s MySym
  -d 'Vendor=SUNW.PCW.LAN,20,IP,1,0'
  -r SUNWfiles -p /var/mydhcp
```

EXAMPLE 3 Adding a Macro Definition

The following command adds the `aruba` macro definition to the `dhcptab` table. Note that symbol/value pairs are bracketed with colons (:).

```
# dhtadm -A -m aruba
  -d ':Timeserv=10.0.0.10 10.0.0.11:DNSserv=10.0.0.1:'
```

EXAMPLE 4 Modifying a Macro Definition

The following command modifies the `Locale` macro definition, setting the value of the `UTCOffst` symbol to 18000 seconds. Note that any macro definition which includes the definition of the `Locale` macro will inherit this change.

```
# dhtadm -M -m Locale -e 'UTCOffst=18000'
```

EXAMPLE 4 Modifying a Macro Definition *(Continued)***EXAMPLE 5** Deleting a Symbol

The following command deletes the `Timeserv` symbol from the `aruba` macro. Note that any macro definition which includes the definition of the `aruba` macro will inherit this change.

```
# dhtadm -M -m aruba -e 'Timeserv='
```

EXAMPLE 6 Adding a Symbol to a Macro

The following command adds the `Hostname` symbol to the `aruba` macro. Note that the `Hostname` symbol takes no value, and thus requires the special value `_NULL_VALUE_`. Note also that any macro definition which includes the definition of the `aruba` macro will inherit this change.

```
# dhtadm -M -m aruba -e 'Hostname=_NULL_VALUE_'
```

EXAMPLE 7 Renaming a Macro

The following command renames the `Locale` macro to `MyLocale`. Note that any `Include` statements in macro definitions which include the `Locale` macro will also need to be changed.

```
# dhtadm -M -m Locale -n MyLocale
```

EXAMPLE 8 Deleting a Symbol Definition

The following command deletes the `MySym` symbol definition. Note that any macro definitions which use `MySym` will need to be modified.

```
# dhtadm -D -s MySym
```

EXAMPLE 9 Removing a `dhcptab`

The following command removes the `dhcptab` table in the NIS+ directory specified.

```
# dhtadm -R -r SUNWnisplus -p Test.Nis.Plus.
```

EXAMPLE 10 Printing a `dhcptab`

The following command prints to standard output the contents of the `dhcptab` that is located in the data store and path indicated in the `dhcpsvc.conf` file:

```
# dhtadm -P
```

dhtadm(1M)

EXAMPLE 10 Printing a dhcptab (Continued)

EXAMPLE 11 Executing dhtadm in Batch Mode

The following command runs a series of dhtadm commands contained in a batch file:

```
# dhtadm -B addmacros
```

EXIT STATUS

0	Successful completion.
1	Object already exists.
2	Object does not exist.
3	Non-critical error.
4	Critical error.

FILES /etc/inet/dhcpsvc.conf

NAME	disks – creates /dev entries for hard disks attached to the system
SYNOPSIS	<code>/usr/sbin/disks [-C] [-r rootdir]</code>
DESCRIPTION	<p>devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of disks.</p> <p>disks creates symbolic links in the /dev/dsk and /dev/rdisk directories pointing to the actual disk device special files under the /devices directory tree. It performs the following steps:</p> <ol style="list-style-type: none"> 1. disks searches the kernel device tree to see what hard disks are attached to the system. It notes the /devices pathnames for the slices on the drive and determines the physical component of the corresponding /dev/dsk or /dev/rdisk name. 2. The /dev/dsk and /dev/rdisk directories are checked for disk entries – that is, symbolic links with names of the form <code>cN[tN]dNsN</code>, or <code>cN[tN]dNpN</code>, where <i>N</i> represents a decimal number. <i>cN</i> is the logical controller number, an arbitrary number assigned by this program to designate a particular disk controller. The first controller found on the first occasion this program is run on a system, is assigned number 0. <i>tN</i> is the bus-address number of a subsidiary controller attached to a peripheral bus such as SCSI or IPI (the <code>target</code> number for SCSI, and the <code>facility</code> number for IPI controllers). <i>dN</i> is the number of the disk attached to the controller. <i>sN</i> is the <i>slice</i> number on the disk. <i>pN</i> is the FDISK partition number used by <code>fdisk(1M)</code>. (IA Only) 3. If only some of the disk entries are found in /dev/dsk for a disk that has been found under the /devices directory tree, disks creates the missing symbolic links. If none of the entries for a particular disk are found in /dev/dsk, disks checks to see if any entries exist for other disks attached to the same controller, and if so, creates new entries using the same controller number as used for other disks on the same controller. If no other /dev/dsk entries are found for slices of disks belonging to the same physical controller as the current disk, disks assigns the lowest-unused controller number and creates entries for the disk slices using this newly-assigned controller number. <p>disks is run automatically each time a reconfiguration-boot is performed or when <code>add_drv(1M)</code> is executed. When invoking <code>disks(1M)</code> manually, first run <code>drvconfig(1M)</code> to ensure /devices is consistent with the current device configuration.</p>
Notice to Driver Writers	<p>disks considers all devices with a node type of <code>DDI_NT_BLOCK</code>, <code>DDI_NT_BLOCK_CHAN</code>, <code>DDI_NT_CD</code>, <code>DDI_NT_BLOCK_WWN</code> or <code>DDI_NT_CD_CHAN</code> to be disk devices. <code>disks(1M)</code> requires the minor name of disk devices obey the following format conventions.</p> <p>The minor name for block interfaces consists of a single lowercase ASCII character, a through u. The minor name for character (raw) interfaces consists of a single lowercase ASCII character, a through u, followed by <code>,raw</code>.</p>

disks(1M)

`disks` translates `a` through `p` to `s0` through `s15`, while it translates `q` through `u` to `p0` through `p4`. SPARC drivers should only use the first 8 slices: `a` through `h`, while IA drivers can use `a` through `u`, with `q` through `u` corresponding to `fdisk(1M)` partitions. `q` represents the entire disk, while `r`, `s`, `t`, and `u` represent up to 4 additional partitions.

To prevent `disks` from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using a node type: `DDI_NT_BLOCK`, `DDI_NT_BLOCK_CHAN`, `DDI_NT_CD`, or `DDI_NT_CD_CHAN` when calling `ddi_create_minor_node(9F)`.

OPTIONS

`-C` Causes `disks` to remove any invalid links after adding any new entries to `/dev/dsk` and `/dev/rdisk`. Invalid links are links which refer to non-existent disk nodes that have been removed, powered off, or are otherwise inaccessible.

`-r rootdir` Causes `disks` to presume that the `/dev/dsk`, `/dev/rdisk` and `/devices` directory trees are found under `rootdir`, not directly under `/`.

ERRORS

If `disks` finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the `/dev` directory, since it cannot determine which of the two alternative logical-to-physical mappings is correct. The links should be manually corrected or removed before another reconfiguration-boot is performed.

EXAMPLES

EXAMPLE 1 Creating The Block And Character Minor Devices From Within The `xkdisk` Driver's `attach(9E)` Function.

The following example demonstrates creating the block and character minor devices from within the `xkdisk` driver's `attach(9E)` function.

```
#include <sys/dkio.h>
/*
 * Create the minor number by combining the instance number
 * with the slice number.
 */
#define MINOR_NUM(i, s)      ((i) << 4 | (s))

int
xkdiskattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, slice;
    char name[8];

    /* other stuff in attach... */

    instance = ddi_get_instance(dip);
    for (slice = 0; slice < V_NUMPAR; slice++) {
        /*
         * create block device interface
         */
        sprintf(name, "%c", slice + 'a');
```

EXAMPLE 1 Creating The Block And Character Minor Devices From Within The `xkdisk` Driver's `attach(9E)` Function. (Continued)

```

        ddi_create_minor_node(dip, name, S_IFBLK,
            MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);

/*
 * create the raw (character) device interface
 */
sprintf(name,"%c,raw", slice + 'a');
ddi_create_minor_node(dip, name, S_IFCHR,
    MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);
    }
}

```

Installing the `xkdisk` disk driver on a SPARCstation 20, with the driver controlling a SCSI disk (target 3 attached to an `esp(7D)` SCSI HBA) and performing a reconfiguration-boot (causing disks to be run) creates the following special files in `/devices`.

```

# ls -l /devices/iommu@f,e0000000/sbus@f,e0001000/espdma@f,400000/esp@f,800000/
brw-r----- 1 root sys  32, 16 Aug 29 00:02 xkdisk@3,0:a
crw-r----- 1 root sys  32, 16 Aug 29 00:02 xkdisk@3,0:a,raw
brw-r----- 1 root sys  32, 17 Aug 29 00:02 xkdisk@3,0:b
crw-r----- 1 root sys  32, 17 Aug 29 00:02 xkdisk@3,0:b,raw
brw-r----- 1 root sys  32, 18 Aug 29 00:02 xkdisk@3,0:c
crw-r----- 1 root sys  32, 18 Aug 29 00:02 xkdisk@3,0:c,raw
brw-r----- 1 root sys  32, 19 Aug 29 00:02 xkdisk@3,0:d
crw-r----- 1 root sys  32, 19 Aug 29 00:02 xkdisk@3,0:d,raw
brw-r----- 1 root sys  32, 20 Aug 29 00:02 xkdisk@3,0:e
crw-r----- 1 root sys  32, 20 Aug 29 00:02 xkdisk@3,0:e,raw
brw-r----- 1 root sys  32, 21 Aug 29 00:02 xkdisk@3,0:f
crw-r----- 1 root sys  32, 21 Aug 29 00:02 xkdisk@3,0:f,raw
brw-r----- 1 root sys  32, 22 Aug 29 00:02 xkdisk@3,0:g
crw-r----- 1 root sys  32, 22 Aug 29 00:02 xkdisk@3,0:g,raw
brw-r----- 1 root sys  32, 23 Aug 29 00:02 xkdisk@3,0:h
crw-r----- 1 root sys  32, 23 Aug 29 00:02 xkdisk@3,0:h,raw

```

`/dev/dsk` will contain the disk entries to the block device nodes in `/devices`

```

# ls -l /dev/dsk
/dev/dsk/c0t3d0s0 -> ../../devices/[...]/xkdisk@3,0:a
/dev/dsk/c0t3d0s1 -> ../../devices/[...]/xkdisk@3,0:b
/dev/dsk/c0t3d0s2 -> ../../devices/[...]/xkdisk@3,0:c
/dev/dsk/c0t3d0s3 -> ../../devices/[...]/xkdisk@3,0:d
/dev/dsk/c0t3d0s4 -> ../../devices/[...]/xkdisk@3,0:e
/dev/dsk/c0t3d0s5 -> ../../devices/[...]/xkdisk@3,0:f
/dev/dsk/c0t3d0s6 -> ../../devices/[...]/xkdisk@3,0:g
/dev/dsk/c0t3d0s7 -> ../../devices/[...]/xkdisk@3,0:h

```

and `/dev/rdisk` will contain the disk entries for the character device nodes in `/devices`

```

# ls -l /dev/rdisk
/dev/rdisk/c0t3d0s0 -> ../../devices/[...]/xkdisk@3,0:a,raw

```

disks(1M)

EXAMPLE 1 Creating The Block And Character Minor Devices From Within The `xkdisk` Driver's `attach(9E)` Function. *(Continued)*

```
/dev/rdisk/c0t3d0s1 -> ../../devices/[...]/xkdisk@3,0:b,raw
/dev/rdisk/c0t3d0s2 -> ../../devices/[...]/xkdisk@3,0:c,raw

Writing Device Drivers

BUGS `disks` silently ignores malformed minor device names.

NAME	diskscan – perform surface analysis						
SYNOPSIS	diskscan [-W] [-n] [-y] <i>raw_device</i>						
DESCRIPTION	<i>diskscan</i> is used by the system administrator to perform surface analysis on a portion of a hard disk. The disk portion may be a raw partition or slice; it is identified using its raw device name. By default, the specified portion of the disk is read (non-destructive) and errors reported on standard error. In addition, a progress report is printed on standard out. The list of bad blocks should be saved in a file and later fed into <i>addbadsec(1M)</i> , which will remap them.						
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -n Causes <i>diskscan</i> to suppress linefeeds when printing progress information on standard out. -W Causes <i>diskscan</i> to perform write and read surface analysis. This type of surface analysis is destructive and should be invoked with caution. -y Causes <i>diskscan</i> to suppress the warning regarding destruction of existing data that is issued when -W is used. 						
OPERANDS	The following operands are supported: <p><i>raw_device</i> The address of the disk drive (see <i>FILES</i>).</p>						
FILES	The raw device should be <code>/dev/rdisk/c? [t?] d? [ps] ?</code> . See <i>disks(1M)</i> for an explanation of SCSI and IDE device naming conventions.						
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes:						
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Architecture</td> <td>IA</td> </tr> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Architecture	IA	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Architecture	IA						
Availability	SUNWcsu						
SEE ALSO	<i>addbadsec(1M)</i> , <i>disks(1M)</i> , <i>fdisk(1M)</i> , <i>fmthard(1M)</i> , <i>format(1M)</i> , <i>attributes(5)</i>						
NOTES	The <i>format(1M)</i> utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the <i>diskscan</i> , <i>addbadsec(1M)</i> , <i>fdisk(1M)</i> , and <i>fmthard(1M)</i> commands available for IA. To format an IDE disk, use the DOS <i>format</i> utility; however, to label, analyze, or repair IDE disks on IA systems, use the Solaris <i>format(1M)</i> utility.						

dispadmin(1M)

NAME	dispadmin – process scheduler administration
SYNOPSIS	dispadmin -l dispadmin -c <i>class</i> -g [-r <i>res</i>] dispadmin -d [<i>class</i>]
DESCRIPTION	<p>The <code>dispadmin</code> command displays or changes process scheduler parameters while the system is running.</p> <p><code>dispadmin</code> does limited checking on the values supplied in <i>file</i> to verify that they are within their required bounds. The checking, however, does not attempt to analyze the effect that the new values have on the performance of the system. Inappropriate values can have a negative effect on system performance. (See <i>System Administration Guide: Basic Administration</i>)</p>
OPTIONS	<p>-l Lists the scheduler classes currently configured in the system.</p> <p>-c <i>class</i> Specifies the class whose parameters are to be displayed or changed. Valid <i>class</i> values are: RT for the real-time class, TS for the time-sharing class, IA for the inter-active class, FSS for the fair-share class, and FX for the fixed-priority class. The time-sharing and inter-active classes share the same scheduler, so changes to the scheduling parameters of one will change those of the other.</p> <p>-d [<i>class</i>] Sets or displays the name of the default scheduling class to be used on reboot by the startup script <code>/etc/init.d/sysetup</code>. If class name is not specified, the name and description of the current default scheduling class is displayed. If class name is specified and is a valid scheduling class name, then it is saved in <code>dispadmin</code>'s private configuration file <code>/etc/dispadmin.conf</code>. Only super-users can set the default scheduling class.</p> <p>-g Gets the parameters for the specified class and writes them to the standard output. Parameters for the real-time class are described in <code>rt_dptbl(4)</code>. Parameters for the time-sharing and inter-active classes are described in <code>ts_dptbl(4)</code>. Parameters for the fair-share class are described in <code>FSS(7)</code>. Parameters for the fixed-priority class are described in <code>fx_dptbl(4)</code>.</p> <p>-r <i>res</i> When using the <code>-g</code> option you may also use the <code>-r</code> option to specify a resolution to be used for outputting the time quantum values. If no resolution is specified, time quantum values are in milliseconds. If <i>res</i> is specified it must be a positive integer between 1 and 100000000 inclusive, and the resolution used is the reciprocal of <i>res</i> in seconds. For example, a <i>res</i> value of 10 yields time quantum values expressed in tenths of a second; a <i>res</i> value of 1000000 yields time quantum values expressed in microseconds. If the time quantum cannot be expressed as an integer in the</p>

specified resolution, it is rounded up to the next integral multiple of the specified resolution.

-s *file* Sets scheduler parameters for the specified class using the values in *file*. These values overwrite the current values in memory—they become the parameters that control scheduling of processes in the specified class. The values in *file* must be in the format output by the **-g** option. Moreover, the values must describe a table that is the same size (has same number of priority levels) as the table being overwritten. Super-user privileges are required in order to use the **-s** option.

Note: The **-g** and **-s** options are mutually exclusive: you may not retrieve the table at the same time you are overwriting it.

EXAMPLES

EXAMPLE 1 Retrieving the Current Scheduler Parameters for the real-time class

The following command retrieves the current scheduler parameters for the real-time class from kernel memory and writes them to the standard output. Time quantum values are in microseconds.

```
dispadmin -c RT -g -r 1000000
```

EXAMPLE 2 Overwriting the Current Scheduler Parameters for the Real-time Class

The following command overwrites the current scheduler parameters for the real-time class with the values specified in `rt.config`.

```
dispadmin -c RT -s rt.config
```

EXAMPLE 3 Retrieving the Current Scheduler Parameters for the Time-sharing Class

The following command retrieves the current scheduler parameters for the time-sharing class from kernel memory and writes them to the standard output. Time quantum values are in nanoseconds.

```
dispadmin -c TS -g -r 1000000000
```

EXAMPLE 4 Overwriting the Current Scheduler Parameters for the Time-sharing Class

The following command overwrites the current scheduler parameters for the time-sharing class with the values specified in `ts.config`.

```
dispadmin -c TS -s ts.config
```

dispadmin(1M)

dmi_cmd(1M)

NAME	dmi_cmd – DMI command line interface utility
SYNOPSIS	<pre>dmi_cmd -AL -c <i>compId</i> -g <i>groupId</i> [-dp] [-a <i>attrId</i>] [-m <i>max-count</i>] [-r <i>req-mode</i>] [-s <i>hostname</i>] dmi_cmd -CD -c <i>compId</i> [-s <i>hostname</i>] dmi_cmd -CI <i>mif-file</i> [-s <i>hostname</i>] dmi_cmd -CL [-dp] [-c <i>compId</i>] [-m <i>max-count</i>] [-r <i>req-mode</i>] [-s <i>hostname</i>] dmi_cmd -GD -c <i>compId</i> -g <i>groupId</i> [-s <i>hostname</i>] dmi_cmd -GI <i>schema-file</i> -c <i>compId</i> [-s <i>hostname</i>] dmi_cmd -GL -c <i>compId</i> -g <i>groupId</i> [-dp] [-m <i>max-count</i>] [-r <i>req-mode</i>] [-s <i>hostname</i>] dmi_cmd -GM -c <i>compId</i> [-m <i>max-count</i>] [-s <i>hostname</i>] dmi_cmd -h dmi_cmd -ND -c <i>compId</i> -l <i>language-string</i> [-s <i>hostname</i>] dmi_cmd -NI <i>schema-file</i> -c <i>compId</i> [-s <i>hostname</i>] dmi_cmd -NL -c <i>compId</i> [-s <i>hostname</i>] dmi_cmd -V [-s <i>hostname</i>] dmi_cmd -W <i>config-file</i> [-s <i>hostname</i>] dmi_cmd -X [-s <i>hostname</i>]</pre>
DESCRIPTION	<p>The dmi_cmd utility provides the ability to:</p> <ul style="list-style-type: none">■ Obtain version information about the DMI Service Provider■ Set the configuration to describe the language required by the management application■ Obtain configuration information describing the current language in use for the session■ Install components into the database■ List components in a system to determine what is installed■ Delete an existing component from the database■ Install group schemas to an existing component in the database■ List class names for all groups in a component■ List the groups within a component■ Delete a group from a component■ Install a language schema for an existing component in the database■ List the set of language mappings installed for a specified component■ Delete a specific language mapping for a component

- List the properties for one or more attributes in a group

OPTIONS

The following options are supported:

-a <i>attrId</i>	Specify an attribute by its ID (positive integer). The default value is 0.
-AL	List the attributes for the specified component.
-c <i>compId</i>	Specify a component by its ID (positive integer). The default value is 0.
-CD	Delete the specified component.
-CI <i>mif-file</i>	Install the component described in the <i>mif-file</i> .
-CL	List component information.
-d	Display descriptions.
-g <i>groupId</i>	Specify a group by its ID (positive integer). The default value is 0.
-GD	Delete a group for the specified component.
-GI <i>schema-file</i>	Install the group schema specified in <i>schema-file</i> .
-GL	List the groups for the specified component.
-GM	List the class names for the specified component.
-h	Help. Print the command line usage.
-l <i>language-string</i>	Specify a language mapping.
-m <i>max-count</i>	Specify the maximum number of components to display.
-ND	Delete a language mapping for the specified component.
-NI <i>schema-file</i>	Install the language schema specified in <i>schema-file</i> .
-NL	List the language mappings for a specified component.
-p	Display the pragma string.
-r <i>req-mode</i>	Specify the request mode. The valid values are: <ol style="list-style-type: none"> 1 DMI_UNIQUE - access the specified item (or table row). 2 DMI_FIRST - access the first item. 3 DMI_NEXT - access the next item. The default request mode is 1 DMI_UNIQUE.
-s <i>hostname</i>	Specify the host machine on which <code>dmi.spd</code> is running. The default host is the local host.

dmi_cmd(1M)

- V Version. Prints version information about the DMI Service Provider.
- w *config-file* Set the configuration specified in *config-file* to *dmispd*.
- X Retrieve configuration information describing the current language in use.

EXIT STATUS The following error values are returned:

- 0 Successful completion.
- 1 An error occurred.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

dminfo(1M)

NAME	dminfo – report information about a device entry in a device maps file
SYNOPSIS	dminfo [-v] [-a] [-f <i>pathname</i>] dminfo [-v] [-a] [-f <i>pathname</i>] -n <i>dev</i> -name... dminfo [-v] [-a] [-f <i>pathname</i>] -d <i>dev</i> -path... dminfo [-v] [-a] [-f <i>pathname</i>] -t <i>dev</i> -type... dminfo [-v] [-f <i>pathname</i>] -u <i>dm</i> -entry
DESCRIPTION	dminfo reports and updates information about the <code>device_maps(4)</code> file.
OPTIONS	<p>-v Verbose. Print the requested entry or entries, one line per entry, on the standard output. If no entries are specified, all are printed.</p> <p>-a Succeed if any of the requested entries are found. If used with -v, all entries that match the requested case(s) are printed.</p> <p>-f <i>pathname</i> Use a <code>device_maps</code> file with <i>pathname</i> instead of <code>/etc/security/device_maps</code>.</p> <p>-n <i>dev-name</i> Search by <i>dev-name</i>. Search <code>device_maps(4)</code> for a <i>device_name</i> field matching <i>dev-name</i>. This option cannot be used with -d, -t or -u .</p> <p>-d <i>dev-path</i> Search by <i>dev-path</i>. Search <code>device_maps(4)</code> for a device special pathname in the <i>device_list</i> field matching the <i>dev-path</i> argument. This option cannot be used with -n, -t or -u .</p> <p>-t <i>dev-type</i> Search by <i>dev-type</i>. Search <code>device_maps(4)</code> for a <i>device_type</i> field matching the given <i>dev-type</i>. This option cannot be used with -d, -n or -u .</p> <p>-u <i>dm-entry</i> Update the <code>device_maps(4)</code> file. This option is provided to add entries to the <code>device_maps(4)</code> file. The <i>dm-entry</i> must be a complete <code>device_maps(4)</code> file entry. The <i>dm-entry</i> has fields, as in the <code>device_maps</code> file. It uses the colon (:) as a field separator, and white space as the <i>device_list</i> subfield separators. The <i>dm-entry</i> is not made if any fields are missing, or if the <i>dm-entry</i> would be a duplicate. The default device maps file can be updated only by the super user.</p>
DIAGNOSTICS	dminfo returns an exit code of 0 if successful, 1 if the request failed, and 2 if the invocation syntax was incorrect.

FILES /etc/security/device_maps

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

NOTES The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

dmispd(1M)

NAME dmispd – Sun Solstice Enterprise DMI Service Provider

SYNOPSIS `/usr/lib/dmi/dmispd [-h] [-c config-dir] [-d debug-level]`

DESCRIPTION The DMI Service Provider, `dmispd`, is the core of the DMI solution. Management applications and Component instrumentations communicate with each other through the Service Provider. The Service Provider coordinates and arbitrates requests from the management application to the specified component instrumentations. The Service Provider handles runtime management of the Component Interface (CI) and the Management Interface (MI), including component installation, registration at the MI and CI level, request serialization and synchronization, event handling for CI, and general flow control and housekeeping.

OPTIONS The following options are supported:

- `-c config-dir` Specify the full path of the directory containing the `dmispd.conf` configuration file. The default directory is `/etc/dmi/conf`.
- `-d debug-level` Debug. Levels from 0 to 5 are supported, giving various levels of debug information. The default is 0, meaning no debug information is given.

If this option is omitted, then `dmispd` is run as a daemon process.

- `-h` Help. Print the command line usage.

EXIT STATUS The following error values are returned:

- 0 Successful completion.
- 1 An error occurred.

FILES `/etc/dmi/conf/dmispd.conf` DMI Service Provider configuration file

NAME	dnskeygen – generate public, private, and shared secret keys for DNS
SYNOPSIS	dnskeygen [[-DHR] <i>size</i>] [-F] [-zhu] [-a] [-c] [-p <i>num</i>] [-s <i>num</i>] -n <i>name</i>
DESCRIPTION	<p>The <code>dnskeygen</code> utility is a tool to generate and maintain keys for DNS security with the Domain Name System (“DNS”). Use <code>dnskeygen</code> to generate public and private keys to authenticate zone data or shared secret keys for request and transaction signatures.</p> <p><code>dnskeygen</code> stores each key in two files:</p> <pre>K<name>+<algorithm>+<footprint>.private</pre> <p>and</p> <pre>K<name>+<algorithm>+<footprint>.key</pre> <p>The key is stored in a portable format within <code>K<name>+<alg>+<footprint>.private</code>. The public key is stored in <code>K<name>+<alg>+<footprint>.private</code> in the DNS zone file format:</p> <pre><name> IN KEY <flags><algorithm><protocol><exponent modulus></pre> <p>The underlying cryptographic math is done by the DNSSAFE and Foundation Toolkit libraries.</p>
OPTIONS	<p>The <code>dnskeygen</code> utility supports the following options:</p> <ul style="list-style-type: none"> -D Generate a DSA/DSS key. The value of <i>size</i> must be one of the following: 512, 576, 640, 704, 768, 832, 896, 960 or 1024. -F Use a large exponent for key generation. Use for RSA only. -H Generate a HMAC-MD5 key. The value of <i>size</i> must be between 128 and 504. -R Generate an RSA key. The value of <i>size</i> must be between 512 and 4096. -a Cannot use key for authentication. -c Cannot use key for encryption. -h Generate host or service key. -n <i>name</i> Set the key’s name to <i>name</i>. -p <i>num</i> Set the key’s protocol field to <i>num</i>. The values for <i>num</i> are as follows: <ul style="list-style-type: none"> 3 If -z or -h is specified (DNSSEC), this is the default value. 2 Unless specified, the default value for all other options.

dnskeygen(1M)

- 1 Use this value for TLS.
- 4 Use this value for IPSEC.
- 255 Use this value for ANY.
- s *num* Set the key's strength field to *num*. The default value of *num* is 0.
- u Generate User key, for example, for email.
- z Generate Zone key for DNS validation.

NAME	domainname – Set or display name of the current domain				
SYNOPSIS	domainname [<i>name-of-domain</i>]				
DESCRIPTION	<p>Without an argument, domainname displays the name of the current domain, which typically encompasses a group of <i>hosts</i> or <i>passwd</i> entries under the same administration. The domainname command is used by various components of Solaris to resolve names for types such as <i>passwd</i>, <i>hosts</i> and <i>aliases</i>. By default, various naming services such as NIS, NIS+, the Internet Domain Name Service (DNS) and <i>sendmail</i>(1M) use this domainname to resolve names. The domainname is normally a valid Internet domain name.</p> <p>The domainname for various naming services can also be set by other means. For example, <i>ypinit</i> can be used to specify a different domain for all NIS calls. The file <i>/etc/resolv.conf</i> can be used to specify a different domain for DNS lookups. For <i>sendmail</i>, the domainname can be specified through the <i>sendmail_vars</i> entry in the <i>/etc/nsswitch.conf</i> file, or through the <i>/etc/mail/sendmail.cf</i> file. Only the superuser can set the name of the domain by specifying the new domainname as an argument. The domain name of the machine is usually set during boot-time through the domainname command in the <i>/etc/init.d/inetinit</i> file. If the new domain name is not saved in the <i>/etc/defaultdomain</i> file, the machine will revert back to the old domain after rebooting.</p>				
FILES	<p><i>/etc/defaultdomain</i></p> <p><i>/etc/init.d/inetinit</i></p> <p><i>/etc/mail/sendmail.cf</i></p> <p><i>/etc/nsswitch.conf</i></p> <p><i>/etc/resolv.conf</i></p>

drvconfig(1M)

NAME	drvconfig – configure the /devices directory
SYNOPSIS	drvconfig [-bn] [-a <i>alias_name</i>] [-c <i>class_name</i>] [-i <i>drivername</i>] [-m <i>major_num</i>] [-r <i>rootdir</i>]
DESCRIPTION	<p>devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of drvconfig.</p> <p>The default operation of <code>drvconfig</code> is to create the /devices directory tree that describes, in the filesystem namespace, the hardware layout of a particular machine. Hardware devices present on the machine and powered on as well as pseudo-drivers are represented under /devices. Normally this command is run automatically after a new driver has been installed (with <code>add_drv(1M)</code>) and the system has been rebooted.</p>
/etc/minor_perm file	<p><code>drvconfig</code> reads the /etc/minor_perm file to obtain permission information and applies the permissions only to nodes that it has just created. It does not change permissions on already existing nodes. The format of the /etc/minor_perm file is as follows:</p> <pre><i>name</i> : <i>minor_name</i> <i>permissions</i> <i>owner</i> <i>group</i></pre> <p><i>minor_name</i> may be the actual name of the minor node, or contain shell metacharacters to represent several minor nodes (see <code>sh(1)</code>).</p> <p>For example:</p> <pre>sd:* 0640 root sys zs:[a-z],cu 0600 uucp uucp mm:kmem 0640 root bin</pre> <p>The first line sets all devices exported by the <code>sd</code> node to 0640 permissions, owned by <code>root</code>, with group <code>sys</code>. In the second line, devices such as <code>a, cu</code> and <code>z, cu</code> exported by the <code>zs</code> driver are set to 0600 permission, owned by <code>uucp</code>, with group <code>uucp</code>. In the third line the <code>kmem</code> device exported by the <code>mm</code> driver is set to 0640 permission, owned by <code>root</code>, with group <code>bin</code>.</p>
OPTIONS	<p>The following options may be of use to system administrators and driver developers:</p> <ul style="list-style-type: none">-i <i>drivername</i> Only configure the devices for the named driver. The following options are used by the implementation of <code>add_drv(1M)</code> and <code>rem_drv(1M)</code>, and may not be supported in future versions of Solaris:-b Add a new major number to name binding into the kernel's internal <code>name_to_major</code> tables. This option is not normally used directly, but is used by other utilities such as <code>add_drv(1M)</code>. Use of the <code>-b</code> option requires that <code>-i</code> and <code>-m</code> be used also. No /devices entries are created.-n Do not try to load and attach any drivers, or if the <code>-i</code> option is given, do not try to attach the driver named <i>drivername</i>.

- a *alias_name* Add the name *alias_name* to the list of aliases that this driver is known by. This option, if used, must be used with the -m *major_num*, the -b and the -i *drivername* options.
- c *class_name* The driver being added to the system exports the class *class_name*. This option is not normally used directly, but is used by other utilities. It is only effective when used with the -b option.
- m *major_num* Specify the major number *major_num* for this driver to add to the kernel's *name_to_major* binding tables.
- r *rootdir* Build the device tree under the directory specified by *rootdir* instead of the default */devices* directory.

EXIT STATUS 0 Successful completion.
 non-zero An error occurred.

FILES */devices* device nodes directory
 /etc/minor_perm minor mode permissions
 /etc/name_to_major major number binding
 /etc/driver_classes driver class binding file

dsvclockd(1M)

- NAME** dsvclockd – DHCP service lock daemon
- SYNOPSIS** `/usr/lib/inet/dsvclockd [-d 1 | 2] [-f] [-v]`
- DESCRIPTION** `dsvclockd` is a daemon that works in conjunction with the Dynamic Host Configuration Protocol (DHCP) Data Service Library (`libdhcpsvc`) to provide synchronization guarantees for DHCP data store modules that want to utilize its services. The daemon is started on demand by `libdhcpsvc`. The `dsvclockd` daemon should be started manually only if command line options need to be specified.
- OPTIONS** The following options are supported:
- `-d 1 | 2` Set debug level. Two levels of debugging are currently available, 1 and 2. Level 2 is more verbose.
 - `-f` Run in the foreground instead of as a daemon process. When this option is used, messages are sent to standard error instead of to `syslog(3C)`.
 - `v` Provide verbose output.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:
- | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWdhcsu |
| Interface Stability | Unstable |
- SEE ALSO** `syslog(3C)`, `attributes(5)`

NAME	dumpadm – configure operating system crash dump
SYNOPSIS	<code>/usr/sbin/dumpadm [-nuy] [-c <i>content-type</i>] [-d <i>dump-device</i>] [-m <i>mink</i> <i>minm</i> <i>min%</i>] [-s <i>savecore-dir</i>] [-r <i>root-dir</i>]</code>
DESCRIPTION	<p>The dumpadm program is an administrative command that manages the configuration of the operating system crash dump facility. A crash dump is a disk copy of the physical memory of the computer at the time of a fatal system error. When a fatal operating system error occurs, a message describing the error is printed to the console. The operating system then generates a crash dump by writing the contents of physical memory to a predetermined dump device, which is typically a local disk partition. The dump device can be configured by way of dumpadm. Once the crash dump has been written to the dump device, the system will reboot.</p> <p>Fatal operating system errors can be caused by bugs in the operating system, its associated device drivers and loadable modules, or by faulty hardware. Whatever the cause, the crash dump itself provides invaluable information to your support engineer to aid in diagnosing the problem. As such, it is vital that the crash dump be retrieved and given to your support provider. Following an operating system crash, the savecore(1M) utility is executed automatically during boot to retrieve the crash dump from the dump device, and write it to a pair of files in your file system named <i>unix.X</i> and <i>vmcore.X</i>, where X is an integer identifying the dump. Together, these data files form the <i>saved crash dump</i>. The directory in which the crash dump is saved on reboot can also be configured using dumpadm.</p> <p>By default, the dump device is configured to be an appropriate swap partition. Swap partitions are disk partitions reserved as virtual memory backing store for the operating system, and thus no permanent information resides there to be overwritten by the dump. See swap(1M). To view the current dump configuration, execute dumpadm with no arguments:</p> <pre>example# dumpadm Dump content: kernel pages Dump device: /dev/dsk/c0t0d0s1 (swap) Savecore directory: /var/crash/saturn Savecore enabled: yes</pre> <p>When no options are specified, dumpadm prints the current crash dump configuration. The example shows the set of default values: the dump content is set to kernel memory pages only, the dump device is a swap disk partition, the directory for savecore files is set to <i>/var/crash/hostname</i>, and savecore is set to run automatically on reboot.</p> <p>When one or more options are specified, dumpadm verifies that your changes are valid, and if so, reconfigures the crash dump parameters and displays the resulting configuration. You must be root to view or change dump parameters.</p>
OPTIONS	The following options are supported:

dumpadm(1M)

<i>-c content-type</i>	<p>Modify the dump configuration so that the crash dump consists of the specified dump content. The content should be one of the following:</p> <table><tr><td><i>kernel</i></td><td>Kernel memory pages only.</td></tr><tr><td><i>all</i></td><td>All memory pages.</td></tr><tr><td><i>curproc</i></td><td>Kernel memory pages, and the memory pages of the process whose thread was currently executing on the CPU on which the crash dump was initiated. If the thread executing on that CPU is a kernel thread not associated with any user process, only kernel pages will be dumped.</td></tr></table>	<i>kernel</i>	Kernel memory pages only.	<i>all</i>	All memory pages.	<i>curproc</i>	Kernel memory pages, and the memory pages of the process whose thread was currently executing on the CPU on which the crash dump was initiated. If the thread executing on that CPU is a kernel thread not associated with any user process, only kernel pages will be dumped.
<i>kernel</i>	Kernel memory pages only.						
<i>all</i>	All memory pages.						
<i>curproc</i>	Kernel memory pages, and the memory pages of the process whose thread was currently executing on the CPU on which the crash dump was initiated. If the thread executing on that CPU is a kernel thread not associated with any user process, only kernel pages will be dumped.						
<i>-d dump-device</i>	<p>Modify the dump configuration to use the specified dump device. The dump device may one of the following:</p> <table><tr><td><i>dump-device</i></td><td>A specific dump device specified as an absolute pathname, such as <i>/dev/dsk/cNtNdNsN</i>.</td></tr><tr><td><i>swap</i></td><td>If the special token <i>swap</i> is specified as the dump device, <i>dumpadm</i> examines the active swap entries and selects the most appropriate entry to configure as the dump device. See <i>swap(1M)</i>. Refer to the NOTES below for details of the algorithm used to select an appropriate swap entry. When the system is first installed, <i>dumpadm</i> uses <i>swap</i> to determine the initial dump device setting.</td></tr></table>	<i>dump-device</i>	A specific dump device specified as an absolute pathname, such as <i>/dev/dsk/cNtNdNsN</i> .	<i>swap</i>	If the special token <i>swap</i> is specified as the dump device, <i>dumpadm</i> examines the active swap entries and selects the most appropriate entry to configure as the dump device. See <i>swap(1M)</i> . Refer to the NOTES below for details of the algorithm used to select an appropriate swap entry. When the system is first installed, <i>dumpadm</i> uses <i>swap</i> to determine the initial dump device setting.		
<i>dump-device</i>	A specific dump device specified as an absolute pathname, such as <i>/dev/dsk/cNtNdNsN</i> .						
<i>swap</i>	If the special token <i>swap</i> is specified as the dump device, <i>dumpadm</i> examines the active swap entries and selects the most appropriate entry to configure as the dump device. See <i>swap(1M)</i> . Refer to the NOTES below for details of the algorithm used to select an appropriate swap entry. When the system is first installed, <i>dumpadm</i> uses <i>swap</i> to determine the initial dump device setting.						
<i>-m mink minm min%</i>	<p>Create a <i>minfree</i> file in the current <i>savecore</i> directory indicating that <i>savecore</i> should maintain at least the specified amount of free space in the file system where the <i>savecore</i> directory is located. The <i>min</i> argument can be one of the following:</p> <table><tr><td><i>k</i></td><td>A positive integer suffixed with the unit <i>k</i> specifying kilobytes.</td></tr><tr><td><i>m</i></td><td>A positive integer suffixed with the unit <i>m</i> specifying megabytes.</td></tr></table>	<i>k</i>	A positive integer suffixed with the unit <i>k</i> specifying kilobytes.	<i>m</i>	A positive integer suffixed with the unit <i>m</i> specifying megabytes.		
<i>k</i>	A positive integer suffixed with the unit <i>k</i> specifying kilobytes.						
<i>m</i>	A positive integer suffixed with the unit <i>m</i> specifying megabytes.						

dumpadm(1M)

<code>%</code>	<p>A % symbol, indicating that the <code>minfree</code> value should be computed as the specified percentage of the total current size of the file system containing the <code>savecore</code> directory. The <code>savecore</code> command will consult the <code>minfree</code> file, if present, prior to writing the dump files. If the size of these files would decrease the amount of free disk space below the <code>minfree</code> threshold, no dump files are written and an error message is logged. The administrator should immediately clean up the <code>savecore</code> directory to provide adequate free space, and re-execute the <code>savecore</code> command manually. The administrator can also specify an alternate directory on the <code>savecore</code> command-line.</p>
<code>-n</code>	<p>Modify the dump configuration to not run <code>savecore</code> automatically on reboot. This is not the recommended system configuration; if the dump device is a swap partition, the dump data will be overwritten as the system begins to swap. If <code>savecore</code> is not executed shortly after boot, crash dump retrieval may not be possible.</p>
<code>-r root-dir</code>	<p>Specify an alternate root directory relative to which <code>dumpadm</code> should create files. If no <code>-r</code> argument is specified, the default root directory "/" is used.</p>
<code>-s savecore-dir</code>	<p>Modify the dump configuration to use the specified directory to save files written by <code>savecore</code>. The directory should be an absolute path and exist on the system. If upon reboot the directory does not exist, it will be created prior to the execution of <code>savecore</code>. See the NOTES section below for a discussion of security issues relating to access to the <code>savecore</code> directory. The default <code>savecore</code> directory is <code>/var/crash/hostname</code> where is the output of the <code>-n</code> option to the <code>uname(1)</code> command.</p>
<code>-u</code>	<p>Forcibly update the kernel dump configuration based on the contents of <code>/etc/dumpadm.conf</code>. Normally this option is used only on reboot by the startup script <code>/etc/init.d/savecore</code>, when the <code>dumpadm</code> settings from the previous boot must be restored. Your dump configuration is saved in the configuration file for this purpose. If the configuration file is missing or contains invalid values for any dump properties, the default values are substituted. Following the update,</p>

dumpadm(1M)

the configuration file is resynchronized with the kernel dump configuration.

-y Modify the dump configuration to automatically run `savecore` on reboot. This is the default for this dump setting.

EXAMPLES **EXAMPLE 1** Reconfiguring The Dump Device To A Dedicated Dump Device:

The following command reconfigures the dump device to a dedicated dump device:

```
example# dumpadm -d /dev/dsk/c0t2d0s2
```

```
    Dump content: kernel pages
    Dump device: /dev/dsk/c0t2d0s2 (dedicated)
    Savecore directory: /var/crash/saturn
    Savecore enabled: yes
```

EXIT STATUS The following exit values are returned:

- 0 Dump configuration is valid and the specified modifications, if any, were made successfully.
- 1 A fatal error occurred in either obtaining or modifying the dump configuration.
- 2 Invalid command line options were specified.

FILES /dev/dump
/etc/init.d/savecore
/etc/dumpadm.conf
savecore-directory/minfree

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

Dump Device Selection

When the special swap token is specified as the argument to `dumpadm -d` the utility will attempt to configure the most appropriate swap device as the dump device. `dumpadm` configures the largest swap block device as the dump device; if no block devices are available for swap, the largest swap entry is configured as the dump device. If no swap entries are present, or none can be configured as the dump device, a warning message will be displayed. While local and remote swap files can be configured as the dump device, this is not recommended.

**Dump
Device/Swap
Device Interaction**

In the event that the dump device is also a swap device, and the swap device is deleted by the administrator using the `swap -d` command, the `swap` command will automatically invoke `dumpadm -d swap` in order to attempt to configure another appropriate swap device as the dump device. If no swap devices remain or none can be configured as the dump device, the crash dump will be disabled and a warning message will be displayed. Similarly, if the crash dump is disabled and the administrator adds a new swap device using the `swap -a` command, `dumpadm -d swap` will be invoked to re-enable the crash dump using the new swap device.

Once `dumpadm -d swap` has been issued, the new dump device is stored in the configuration file for subsequent reboots. If a larger or more appropriate swap device is added by the administrator, the dump device is not changed; the administrator must re-execute `dumpadm -d swap` to reselect the most appropriate device from the new list of swap devices.

**Minimum Free
Space**

If the `dumpadm -m` option is used to create a `minfree` file based on a percentage of the total size of the file system containing the `savecore` directory, this value is not automatically recomputed if the file system subsequently changes size. In this case, the administrator must re-execute `dumpadm -m` to recompute the `minfree` value. If no such file exists in the `savecore` directory, `savecore` will default to a free space threshold of one megabyte. If no free space threshold is desired, a `minfree` file containing size 0 can be created.

Security Issues

If, upon reboot, the specified `savecore` directory is not present, it will be created prior to the execution of `savecore` with permissions 0700 (read, write, execute by owner only) and owner `root`. It is recommended that alternate `savecore` directories also be created with similar permissions, as the operating system crash dump files themselves may contain secure information.

editmap(1M)

NAME	editmap – query and edit single records in database maps for sendmail
SYNOPSIS	editmap -C <i>file</i> [-N] [-f] [-q -u -x] <i>maptype mapname key</i> [" <i>value</i> "...]
DESCRIPTION	<p>The <code>editmap</code> command queries or edits one record in a database maps used by the keyed map lookups in <code>sendmail(1M)</code>. Arguments are passed on the command line and output (for queries) is directed to standard output.</p> <p>Depending on how it is compiled, <code>editmap</code> handles up to three different database formats, selected using the <i>maptype</i> parameter. See OPERANDS.</p> <p>If the <code>TrustedUser</code> option is set in the <code>sendmail</code> configuration file and <code>editmap</code> is invoked as root, the generated files are owned by the specified <code>TrustedUser</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-C <i>file</i> Use the specified <code>sendmail</code> configuration file (<i>file</i>) to look up the <code>TrustedUser</code> option.-f Disable the folding of all upper case letters in the key to lower case. Normally, all upper case letters in the key are folded to upper case. This is intended to mesh with the -f flag in the <code>K</code> line in <code>sendmail.cf</code>. The value is never case folded.-N Include the null byte that terminates strings in the map (for alias maps).-q Query the map for the specified key. If found, print value to standard output and exit with 0. If not found then print an error message to <code>stdout</code> and exit with <code>EX_UNAVAILABLE</code>.-u Update the record for key with value or inserts a new record if one doesn't exist. Exits with 0 on success or <code>EX_IOERR</code> on failure.-x Delete the specific key from the map. Exit with 0 on success or <code>EX_IOERR</code> on failure.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"><i>key</i> The left hand side of a record. <p>Each record is of the form:</p> <p style="padding-left: 40px;"><i>key value</i></p> <p><i>key</i> and <i>value</i> are separated by white space.</p> <ul style="list-style-type: none"><i>mapname</i> File name of the database map being created.<i>maptype</i> Specifies the database format. The following <i>maptype</i> parameters are available:<ul style="list-style-type: none"><code>dbm</code> Specifies DBM format maps.<code>btree</code> Specifies B-Tree format maps.

hash Specifies hash format maps.

value The right hand side of a record.

Each record is of the form:

key value

key and *value* are separated by white space.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsndmu

SEE ALSO `makemap(1M)`, `sendmail(1M)`, `attributes(5)`

edquota(1M)

NAME	edquota – edit user quotas for ufs file system
SYNOPSIS	edquota [-p <i>proto_user</i>] <i>username...</i> edquota -t
DESCRIPTION	<p>edquota is a quota editor. One or more users may be specified on the command line. For each user a temporary file is created with an ASCII representation of the current disk quotas for that user for each mounted ufs file system that has a <code>quotas</code> file, and an editor is then invoked on the file. The quotas may then be modified, new quotas added, etc. Upon leaving the editor, edquota reads the temporary file and modifies the binary quota files to reflect the changes made.</p> <p>The editor invoked is <code>vi(1)</code> unless the <code>EDITOR</code> environment variable specifies otherwise.</p> <p>Only the super-user may edit quotas. In order for quotas to be established on a file system, the root directory of the file system must contain a file, owned by root, called <code>quotas</code>. (See <code>quotaon(1M)</code>.)</p> <p><i>proto_user</i> and <i>username</i> can be numeric, corresponding to the UID of a user. Unassigned UIDs may be specified; unassigned names may not. In this way, default quotas can be established for users who are later assigned a UID.</p> <p>If no options are specified, the temporary file created will have one or more lines of the form</p> <pre>fs <i>mount_point</i> blocks (soft =<i>number</i>, hard =<i>number</i>) inodes (soft =<i>number</i>, hard =<i>number</i>)</pre> <p>Where a block is considered to be a 1024 byte (1K) block.</p> <p>The <i>number</i> fields may be modified to reflect desired values.</p>
OPTIONS	<p>-p Duplicate the quotas of the <i>proto_user</i> specified for each <i>username</i> specified. This is the normal mechanism used to initialize quotas for groups of users.</p> <p>-t Edit the soft time limits for each file system. If the time limits are zero, the default time limits in <code>/usr/include/sys/fs/ufs_quota.h</code> are used. The temporary file created will have one or more lines of the form</p> <pre>fs <i>mount_point</i> blocks time limit = <i>number</i> <i>tmunit</i>, files time limit = <i>number</i> <i>tmunit</i></pre> <p><i>tmunit</i> may be one of “month”, “week”, “day”, “hour”, “min” or “sec”; characters appended to these keywords are ignored, so you may write “months” or “minutes” if you prefer. The <i>number</i> and <i>tmunit</i> fields may be modified to set desired values. Time limits are printed in the greatest possible time unit such that the value is greater than</p>

or equal to one. If "default" is printed after the *tmunit*, this indicates that the value shown is zero (the default).

USAGE See `largefile(5)` for the description of the behavior of `edquota` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES `quotas` quota file at the file system root
`/etc/mnttab` table of mounted file systems

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `vi(1)`, `quota(1M)`, `quotacheck(1M)`, `quotaon(1M)`, `repquota(1M)`, `attributes(5)`, `largefile(5)`, `quotactl(7I)`

NOTES `quotacheck(1M)` *must* be invoked when setting initial quota limits for users; if not, the quota limit remains 0 and no changes made with `edquota` will take effect.

Users with a UID greater than 67108864 cannot be given quotas.

eeeprom(1M)

NAME	eeeprom – EEPROM display and load utility
SPARC	<code>/usr/platform/ platform-name /sbin/eeeprom [-] [-f device] [parameter [=value]]</code>
IA	<code>/usr/platform/ platform-name /sbin/eeeprom [-] [-f device] [-I] [mmu-modlist] [parameter [=value]]</code>
DESCRIPTION	<p>eeeprom displays or changes the values of parameters in the EEPROM. It processes parameters in the order given. When processing a <i>parameter</i> accompanied by a <i>value</i>, eeeprom makes the indicated alteration to the EEPROM; otherwise, it displays the <i>parameter's</i> value. When given no parameter specifiers, eeeprom displays the values of all EEPROM parameters. A '-' (hyphen) flag specifies that parameters and values are to be read from the standard input (one <i>parameter</i> or <i>parameter=value</i> per line).</p> <p>Only the super-user may alter the EEPROM contents.</p> <p>eeeprom verifies the EEPROM checksums and complains if they are incorrect.</p> <p><i>platform-name</i> is the name of the platform implementation and can be found using the -i option of uname(1).</p>
SPARC	SPARC based systems implement firmware password protection with eeeprom, using the <i>security-mode</i> , <i>security-password</i> and <i>security-#badlogins</i> properties.
IA	<p>EEPROM storage is simulated using a file residing in the platform-specific boot area. The <code>/platform/platform-name/boot/solaris/bootenv.rc</code> file simulates EEPROM storage.</p> <p>Because IA based systems typically implement password protection in the system BIOS, there is no support for password protection in the eeeprom program. While it is possible to set the <i>security-mode</i>, <i>security-password</i> and <i>security-#badlogins</i> properties on IA based systems, these properties have no special meaning or behavior on IA based systems.</p>
OPTIONS	<p><code>-f device</code> Use <i>device</i> as the EEPROM device.</p>
IA Only	<p><code>-I</code> Initialize boot properties on an IA based system. Only <code>init(1M)</code> run-level initialization scripts should use this option.</p>
IA Only	<p><code>acpi-user-options</code> A configuration variable that controls the use of ACPI. A value of 0x0 attempts to use ACPI if it is available on the system. A value of 0x2 disables the use of ACPI. Defaults to 0x0.</p> <p><code>mmu-modlist</code> A colon-separated list of candidate modules that implement memory management. If <code>mmu-modlist</code> is defined, it overrides the default list derived from the memory configuration on IA based systems. Instead, the first module in the list that is found in <code>/platform/platform-name/kernel/mmu</code> is used.</p>

**NVRAM
CONFIGURATION
PARAMETERS**

Not all OpenBoot systems support all parameters. Defaults vary depending on the system and the PROM revision. See the output in the "Default Value" column of the `printenv` command, as entered at the `ok` (OpenBoot) prompt, to determine the default for your system.

<code>auto-boot?</code>	If <code>true</code> , boots automatically after power-on or reset. Defaults to <code>true</code> .
<code>ansi-terminal?</code>	Configuration variable used to control the behavior of the terminal emulator. The value <code>false</code> makes the terminal emulator stop interpreting ANSI escape sequences; instead, echoes them to the output device. Defaults to <code>true</code> .
<code>boot-command</code>	Command executed if <code>auto-boot?</code> is <code>true</code> . Defaults to <code>boot</code> .
<code>boot-device</code>	Device from which to boot. <i>boot-device</i> may contain 0 or more device specifiers separated by spaces. Each device specifier may be either a prom device alias or a prom device path. The boot prom will attempt to open each successive device specifier in the list beginning with the first device specifier. The first device specifier that opens successfully will be used as the device to boot from. Defaults to <code>disk net</code> .
<code>boot-file</code>	File to boot (an empty string lets the secondary booter choose default). Defaults to empty string.
<code>boot-from</code>	Boot device and file (OpenBoot PROM version 1.x only). Defaults to <code>vmunix</code> .
<code>boot-from-diag</code>	Diagnostic boot device and file (OpenBoot PROM version 1.x only). Defaults to <code>le()unix</code> .
<code>comX-noprobe</code>	Where <i>X</i> is the number of the serial port, prevents device probe on serial port <i>X</i> .
<code>diag-device</code>	Diagnostic boot source device. Defaults to <code>net</code> .
<code>diag-file</code>	File from which to boot in diagnostic mode. Defaults to empty string.
<code>diag-level</code>	Diagnostics level. Values include <code>off</code> , <code>min</code> , <code>max</code> and <code>menus</code> . There may be additional platform-specific values. When set to <code>off</code> , POST is not called. If POST is called, the value is made available as an argument to, and is interpreted by POST. Defaults to platform-dependent.
<code>diag-switch?</code>	If <code>true</code> , run in diagnostic mode. Defaults to <code>false</code> on most desktop systems, <code>true</code> on most servers.

eeeprom(1M)

error-reset-recovery	<p>Recover after an error reset trap. Defaults to platform-specific setting.</p> <p>On platforms supporting this variable, it replaces the <code>watchdog-reboot?</code>, <code>watchdog-sync?</code>, <code>redmode-reboot?</code>, <code>redmode-sync?</code>, <code>sir-sync?</code>, and <code>xir-sync?</code> parameters.</p> <p>The options are:</p> <p><code>none</code> Print a message describing the reset trap and go to OpenBoot PROM's user interface, <i>aka</i> OK prompt.</p> <p><code>sync</code> Invoke OpenBoot PROM's <code>sync</code> word after the reset trap. Some platforms may treat this as <code>none</code> after an externally initiated reset (XIR) trap.</p> <p><code>boot</code> Reboot after the reset trap. Some platforms may treat this as <code>none</code> after an XIR trap.</p>
fcode-debug?	If <code>true</code> , include name parameter for plug-in device FCodes. Defaults to <code>false</code> .
hardware-revision	System version information.
input-device	Input device used at power-on (usually <code>keyboard</code> , <code>ttya</code> , or <code>ttyb</code>). Defaults to <code>keyboard</code> .
keyboard-click?	If <code>true</code> , enable keyboard click. Defaults to <code>false</code> .
keymap	Keymap for custom keyboard.
last-hardware-update	System update information.
load-base	Default load address for client programs. Default value is 16384.
local-mac-address?	If <code>true</code> , network drivers use their own MAC address, not the system's. Defaults to <code>false</code> .
mfg-mode	Manufacturing mode argument for POST. Possible values include <code>off</code> or <code>chamber</code> . The value is passed as an argument to POST. Defaults to <code>off</code> .
mfg-switch?	If <code>true</code> , repeat system self-tests until interrupted with STOP-A. Defaults to <code>false</code> .
nvramrc	Contents of NVRAMRC. Defaults to empty.
oem-banner	Custom OEM banner (enabled by setting <code>oem-banner?</code> to <code>true</code>). Defaults to empty string.
oem-banner?	If <code>true</code> , use custom OEM banner. Defaults to <code>false</code> .

oem-logo	Byte array custom OEM logo (enabled by setting <code>oem-logo?</code> to <code>true</code>). Displayed in hexadecimal.
oem-logo?	If <code>true</code> , use custom OEM logo (else, use Sun logo). Defaults to <code>false</code> .
output-device	Output device used at power-on (usually <code>screen</code> , <code>ttya</code> , or <code>ttyb</code>). Defaults to <code>screen</code> .
redmode-reboot?	Specify <code>true</code> to reboot after a redmode reset trap. Defaults to <code>true</code> . (Sun Enterprise 10000 only.)
redmode-sync?	Specify <code>true</code> to invoke OpenBoot PROM's sync word after a redmode reset trap. Defaults to <code>false</code> . (Sun Enterprise 10000 only.)
sbus-probe-list	Designate which SBus slots are probed and in what order. Defaults to <code>0123</code> .
screen-#columns	Number of on-screen columns (characters/line). Defaults to <code>80</code> .
screen-#rows	Number of on-screen rows (lines). Defaults to <code>34</code> .
scsi-initiator-id	SCSI bus address of host adapter, range 0-7. Defaults to <code>7</code> .
sd-targets	Map SCSI disk units (OpenBoot PROM version 1.x only). Defaults to <code>31204567</code> , which means that unit 0 maps to target 3, unit 1 maps to target 1, and so on.
security-#badlogins	Number of incorrect security password attempts. This property has no special meaning or behavior on IA based systems.
security-mode	Firmware security level (options: <code>none</code> , <code>command</code> , or <code>full</code>). If set to <code>command</code> or <code>full</code> , system will prompt for PROM security password. Defaults to <code>none</code> . This property has no special meaning or behavior on IA based systems.
security-password	Firmware security password (never displayed). Can be set only when <code>security-mode</code> is set to <code>command</code> or <code>full</code> . This property has no special meaning or behavior on IA based systems. <pre>example# eeprom security-password= Changing PROM password: New password: Retype new password:</pre>
selftest-#megs	Megabytes of RAM to test. Ignored if <code>diag-switch?</code> is <code>true</code> . Defaults to <code>1</code> .

eeeprom(1M)

sir-sync?	Specify <code>true</code> to invoke OpenBoot PROM's sync word after a software-initiated reset (SIR) trap. Defaults to <code>false</code> . (Sun Enterprise 10000 only.)
skip-vme-loopback?	If <code>true</code> , POST does not do VMEbus loopback tests. Defaults to <code>false</code> .
st-targets	Map SCSI tape units (OpenBoot PROM version 1.x only). Defaults to <code>45670123</code> , which means that unit 0 maps to target 4, unit 1 maps to target 5, and so on.
sunmon-compat?	If <code>true</code> , display Restricted Monitor prompt (<code>></code>). Defaults to <code>false</code> .
testarea	One-byte scratch field, available for read/write test. Defaults to 0.
tpe-link-test?	Enable 10baseT link test for built-in twisted pair Ethernet. Defaults to <code>true</code> .
ttya-mode	TTYA (baud rate, #bits, parity, #stop, handshake). Defaults to <code>9600, 8, n, 1, -</code> . Fields, in left-to-right order, are: Baud rate: 110, 300, 1200, 4800, 9600 . . . Data bits: 5, 6, 7, 8 Parity: n(none), e(even), o(odd), m(mark), s(space) Stop bits: 1, 1.5, 2 Handshake: -(none), h(hardware:rts/cts), s(software:xon/xoff)
ttyb-mode	TTYB (baud rate, #bits, parity, #stop, handshake). Defaults to <code>9600, 8, n, 1, -</code> . Fields, in left-to-right order, are: Baud rate: 110, 300, 1200, 4800, 9600 . . . Data bits: 5, 6, 7, 8 Stop bits: 1, 1.5, 2 Parity: n(none), e(even), o(odd), m(mark), s(space) Handshake: -(none), h(hardware:rts/cts), s(software:xon/xoff)
ttya-ignore-cd	If <code>true</code> , operating system ignores carrier-detect on TTYA. Defaults to <code>true</code> .

ttyb-ignore-cd	If <code>true</code> , operating system ignores carrier-detect on TTYB. Defaults to <code>true</code> .
tya-rts-dtr-off	If <code>true</code> , operating system does not assert DTR and RTS on TTYA. Defaults to <code>false</code> .
ttyb-rts-dtr-off	If <code>true</code> , operating system does not assert DTR and RTS on TTYB. Defaults to <code>false</code> .
use-nvramrc?	If <code>true</code> , execute commands in NVRAMRC during system start-up. Defaults to <code>false</code> .
version2?	If <code>true</code> , hybrid (1.x/2.x) PROM comes up in version 2.x. Defaults to <code>true</code> .
watchdog-reboot?	If <code>true</code> , reboot after watchdog reset. Defaults to <code>false</code> .
watchdog-sync?	Specify <code>true</code> to invoke OpenBoot PROM's sync word after a watchdog reset trap. Defaults to <code>false</code> . (Sun Enterprise 10000 only.)
xir-sync?	Specify <code>true</code> to invoke OpenBoot PROM's sync word after an XIR trap. Defaults to <code>false</code> . (Sun Enterprise 10000 only.)

EXAMPLES**EXAMPLE 1** Changing the Number of Megabytes of RAM.

The following example demonstrates the method for changing from one to two the number of megabytes of RAM that the system will test.

```
example# eeprom selftest-#megs
selftest-#megs=1
```

```
example# eeprom selftest-#megs=2
```

```
example# eeprom selftest-#megs
selftest-#megs=2
```

EXAMPLE 2 Setting the `auto-boot?` Parameter to `true`.

The following example demonstrates the method for setting the `auto-boot?` parameter to `true`.

```
example# eeprom auto-boot?=true
```

When the `eeprom` command is executed in user mode, the parameters with a trailing question mark (?) need to be enclosed in double quotation marks (" ") to prevent the shell from interpreting the question mark. Preceding the question mark with an escape character (\) will also prevent the shell from interpreting the question mark.

```
example% eeprom "auto-boot?"=true
```

eeeprom(1M)

EXAMPLE 2 Setting the auto-boot? Parameter to true. (Continued)

EXAMPLE 3 Enabling and Disabling PAE Mode

Certain IA machines support Physical Address Extension (PAE) mode. To enable and disable PAE mode on these machines, use commands such as those below.

To enable PAE mode:

```
example# eeeprom mmu-modlist=mmu36
```

To disable PAE mode:

```
example# eeeprom mmu-modlist=mmu32
```

These commands take effect following your next reboot.

FILES

/dev/openprom

Device file

/usr/platform/*platform-name*/sbin/eeeprom

Platform-specific version of eeeprom. Use `uname -i` to obtain *platform-name*.

NAME	efdaemon – embedded FCode interpreter daemon				
SYNOPSIS	<code>/usr/lib/efcode/sparcv9/efdaemon [-d]</code>				
DESCRIPTION	<p>efdaemon, the embedded FCode interpreter daemon, invokes the embedded FCode interpreter when the daemon receives an interpretation request. A new session of the interpreter is started for each unique request by invoking the script <code>/usr/lib/efcode/efcode</code>.</p> <p>efdaemon is used on selected platforms as part of the processing of some dynamic reconfiguration events.</p>				
OPTIONS	<p>The following option is supported:</p> <p><code>-d</code> Set debug output. Log debug messages as LOG_DEBUG level messages by using <code>syslog()</code>. See <code>syslog(3C)</code>.</p>				
FILES	<p><code>/dev/fcode</code> FCode interpreter pseudo device, which is a portal for receipt of FCode interpretation requests</p> <p><code>/usr/lib/efcode/efcode</code> Shell script that invokes the embedded FCode interpreter</p> <p><code>/usr/lib/efcode/interpreter</code> Embedded FCode interpreter</p> <p><code>/usr/lib/efcode/sparcv9/interpreter</code> Embedded FCode interpreter</p>

etrn(1M)

NAME	etrn – start mail queue run
SYNOPSIS	etrn [-v] <i>server-host</i> [<i>client-hosts</i>]
DESCRIPTION	<p>SMTP's ETRN command allows an SMTP client and server to interact, giving the server an opportunity to start the processing of its queues for messages to go to a given host. This is meant to be used in start-up conditions, as well as for mail nodes that have transient connections to their service providers.</p> <p>The <i>etrn</i> utility initiates an SMTP session with the host <i>server-host</i> and sends one or more ETRN commands as follows: If no <i>client-hosts</i> are specified, <i>etrn</i> looks up every host name for which <i>sendmail</i>(1M) accepts email and, for each name, sends an ETRN command with that name as the argument. If any <i>client-hosts</i> are specified, <i>etrn</i> uses each of these as arguments for successive ETRN commands.</p>
OPTIONS	<p><i>etrn</i> has a single option, <i>-v</i>.</p> <p>The normal mode of operation for <i>etrn</i> is to do all of its work silently. The <i>-v</i> option makes it verbose, which causes <i>etrn</i> to display its conversations with the remote SMTP server.</p>
ENVIRONMENT VARIABLES	<p>No environment variables are used. However, at system start-up, <i>/etc/init.d/sendmail</i> reads <i>/etc/default/sendmail</i>. In this file, if the variable <i>ETRN_HOSTS</i> is set, <i>/etc/init.d/sendmail</i> parses this variable and invokes <i>etrn</i> appropriately. <i>ETRN_HOSTS</i> should be of the form:</p> <pre>"s1:c1.1,c1.2 s2:c2.1 s3:c3.1,c3.2,c3.3"</pre> <p>That is, white-space separated groups of <i>server:client</i> where <i>client</i> can be one or more comma-separated names. Note that the <i>:client</i> part is optional. <i>server</i> is the name of the server to prod; a mail queue run is requested for each <i>client</i> name. This is comparable to running:</p> <pre>/usr/lib/sendmail -qR client</pre> <p>on the host <i>server</i>.</p>
EXAMPLES	<p>Inserting the line:</p> <pre>ETRN_HOSTS="s1.domain.com:clnt.domain.com s2.domain.com:clnt.domain.com"</pre> <p>in <i>/etc/default/sendmail</i> results in <i>/etc/init.d/sendmail</i> invoking <i>etrn</i> such that ETRN commands are sent to both <i>s1.domain.com</i> and <i>s2.domain.com</i>, with both having <i>clnt.domain.com</i> as the ETRN argument.</p> <p>The line:</p> <pre>ETRN_HOSTS="server.domain.com:client1.domain.com,client2.domain.com"</pre> <p>results in two ETRN commands being sent to <i>server.domain.com</i>, one with the argument <i>client1.domain.com</i>, the other with the argument <i>client2.domain.com</i>.</p>

The line:

```
ETRN_HOSTS="server1.domain.com server2.domain.com"
```

results in set of a ETRN commands being sent to both `server1.domain.com` and `server2.domain.com`; each set contains one ETRN command for each host name for which `sendmail(1M)` accepts email, with that host name as the argument.

FILES

```
/etc/mail/sendmail.cf
  sendmail configuration file
```

```
/etc/default/sendmail
  variables used by /etc/init.d/sendmail
```

CAVEATS

Not all SMTP servers support ETRN.

fbconfig(1M)

NAME	fbconfig – Frame Buffer configuration utility										
SYNOPSIS	fbconfig [-list -help] fbconfig [-dev <i>device_filename</i>] [-prconf] [-propt] [-res] fbconfig [-dev <i>device_filename</i>] [-res <i>resolution-specification</i>] <i>device_specific_options</i>										
DESCRIPTION	<p>fbconfig is the generic command line interface to query and configure frame buffer attributes.</p> <p>The following form of fbconfig is the interface for the device independent operations performed by fbconfig:</p> fbconfig [-list -help] <p>The following form of fbconfig is the interface for configuring a frame buffer:</p> fbconfig [-dev <i>device_filename</i>] [-prconf] [-propt] [-res] <p>If the -dev option is omitted, the default frame buffer (/dev/fb or /dev/fb0) is assumed. In the absence of specific options, the response will depend upon the device specific configuration program and how it responds to no options</p>										
OPTIONS	<p>The following options are supported:</p> <p>-dev <i>device_filename</i> Specify the FFB special file. The default is /dev/fbs/ffb0.</p> <p>-help Print the fbconfig command usage summary. This is the default option.</p> <p>-list Print the list of installed frame buffers and associated device specific configuration routines.</p> <table><thead><tr><th>Device Filename</th><th>Specific Config Program</th></tr></thead><tbody><tr><td>/dev/fbs/ffb0</td><td>SUNWffb_config</td></tr><tr><td>/dev/fbs/ffb1</td><td>SUNWffb_config</td></tr><tr><td>/dev/fbs/m640</td><td>SUNWm64_config</td></tr><tr><td>/dev/fbs/cgsix0</td><td>not configurable</td></tr></tbody></table> <p>-prconf Print the current hardware configuration.</p> <p>-propt Print the current software configuration.</p>	Device Filename	Specific Config Program	/dev/fbs/ffb0	SUNWffb_config	/dev/fbs/ffb1	SUNWffb_config	/dev/fbs/m640	SUNWm64_config	/dev/fbs/cgsix0	not configurable

/dev/fbs/ffb0	SUNWffb_config										
/dev/fbs/ffb1	SUNWffb_config										
/dev/fbs/m640	SUNWm64_config										
/dev/fbs/cgsix0	not configurable										
OPERANDS	<p>The following operands are supported:</p> <p><i>device_specific_options</i> <i>device_specific_options</i> are specified in the format shown by the -help output, or the corresponding</p>										

device-specific man page.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWfbc

SEE ALSO `afbconfig(1M)`, `ffbconfig(1M)`, `attributes(5)`

LIMITATIONS Because of limitations in the `m64` kernel driver and related software, `fbconfig` (with the `-prconf` option) is unable to distinguish between a current depth of 24 or 8+24. The `-propt` option returns the depth specified in the `OWconfig` file, which will be in effect following the next restart of the window system. The `xwininfo` utility, usually shipped in the package containing frame buffer software (such as `SUNWxwplt`), reports current depth of a specified window.

fdetach(1M)

NAME	fdetach – detach a name from a STREAMS-based file descriptor				
SYNOPSIS	fdetach <i>path</i>				
DESCRIPTION	<p>The <code>fdetach</code> command detaches a STREAMS-based file descriptor from a name in the file system. Use the <i>path</i> operand to specify the path name of the object in the file system name space, which was previously attached. See <code>fattach(3C)</code>.</p> <p>The user must be the owner of the file or a user with the appropriate privileges. All subsequent operations on <i>path</i> will operate on the underlying file system entry and not on the STREAMS file. The permissions and status of the entry are restored to the state they were in before the STREAMS file was attached to the entry.</p>				
OPERANDS	<p>The following operands are supported:</p> <p><i>path</i> Specifies the the path name of the object in the file system name space, which was previously attached.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	fdisk – create or modify fixed disk partition table
SYNOPSIS	fdisk [-o <i>offset</i>] [-s <i>size</i>] [-P <i>fill_patt</i>] [-S <i>geom_file</i>] [-w r d n I B t T g G R] [-F <i>fdisk_file</i>] [[-v] -w { <i>fdisk_file</i> -}] [-h] [-b <i>masterboot</i>] [-A <i>id : act : bhead : bsect : bcyl : ehead : esect : ecyl : rsect : numsect</i>] [-D <i>id : act : bhead: bsect : bcyl : ehead : esect : ecyl : rsect : numsect</i>] <i>rdevice</i>
DESCRIPTION	<p>This command is used to create and modify the partition table, and to install the master boot (IA only) record that is put in the first sector of the fixed disk. This table is used by the first-stage bootstrap (or firmware) to identify parts of the disk reserved for different operating systems, and to identify the partition containing the second-stage bootstrap (the <i>active</i> Solaris partition). The <i>rdevice</i> argument must be used to specify the raw device associated with the fixed disk, for example, /dev/rdisk/c0t0d0p0.</p> <p>The program can operate in three different modes. The first is interactive mode. In interactive mode, the program displays the partition table as it exists on the disk, and then presents a menu allowing the user to modify the table. The menu, questions, warnings, and error messages are intended to be self-explanatory.</p> <p>In interactive mode, if there is no partition table on the disk, the user is given the options of creating a default partitioning or specifying the initial table values. The default partitioning allocates the entire disk for the Solaris system and makes the Solaris system partition active. In either case, when the initial table is created, <i>fdisk</i> also writes out the first-stage bootstrap (IA only) code along with the partition table.</p> <p>The second mode of operation is used for automated entry addition, entry deletion, or replacement of the entire <i>fdisk</i> table. This mode can add or delete an entry described on the command line. In this mode the entire <i>fdisk</i> table can be read from a file replacing the original table. <i>fdisk</i> can also be used to create this file. There is a command line option that will cause <i>fdisk</i> to replace any <i>fdisk</i> table with the default of the whole disk for the Solaris system.</p> <p>The third mode of operation is used for disk diagnostics. In this mode, a section of the disk can be filled with a user specified pattern, and mode sections of the disk can also be read or written.</p>
Menu Options	<p>The menu options for interactive mode given by the <i>fdisk</i> program are:</p> <p>Create a partition</p> <p>This option allows the user to create a new partition. The maximum number of partitions is 4. The program will ask for the type of the partition (SOLARIS, MS-DOS, UNIX, or other). It will then ask for the size of the partition as a percentage of the disk. The user may also enter the letter <i>c</i> at this point, in which case the program will ask for the starting cylinder number and size of the partition in cylinders. If a <i>c</i> is not entered, the program will determine the starting cylinder number where the partition will fit. In either case, if the partition would overlap an existing partition or will not fit, a message is displayed and the program returns to the original menu.</p>

fdisk(1M)

Change Active (Boot from) partition

This option allows the user to specify the partition where the first-stage bootstrap will look for the second-stage bootstrap, otherwise known as the *active* partition.

Delete a partition

This option allows the user to delete a previously created partition. Note that this will destroy all data in that partition.

Use the following options to include your modifications to the partition table at this time or to cancel the session without modifying the table:

Exit

This option writes the new version of the table created during this session with `fdisk` out to the fixed disk, and exits the program.

Cancel

This option exits without modifying the partition table.

OPTIONS

The following options apply to `fdisk`:

`-A id:act:bhead:bsect:bcyl:ehhead:esect:ecyl:rsect:numsect`

Add a partition as described by the argument (see the `-F` option below for the format). Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

`-b master_boot`

Specify the file `master_boot` as the master boot program. The default master boot program is `/usr/lib/fs/ufs/mboot`.

`-B`

Default to one Solaris partition that uses the whole disk.

`-d`

Turn on verbose *debug* mode. This will cause `fdisk` to print its state on `stderr` as it is used. The output from this option should not be used with `-F`.

`-D id:act:bhead:bsect:bcyl:ehhead:esect:ecyl:rsect:numsect`

Delete a partition as described by the argument (see the `-F` option below for the format). Note that the argument must be an exact match or the entry will not be deleted! Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

`-F fdisk_file`

Use `fdisk` file `fdisk_file` to initialize table. Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

The `fdisk_file` contains up to four specification lines. Each line is delimited by a new-line character (`\n`). If the first character of a line is an asterisk (`*`), the line is treated as a comment. Each line is composed of entries that are position-dependent, are separated by "white space" or colons, and have the following format:

```
id act bhead bsect bcyl ehhead esect ecyl rsect numsect
```

where the entries have the following values:

<i>id</i>	This is the type of partition and the correct numeric values may be found in <code>fdisk.h</code> .
<i>act</i>	This is the active partition flag; 0 means not active and 128 means active.
<i>bhead</i>	This is the head where the partition starts. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>bsect</i>	This is the sector where the partition starts. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>bcyl</i>	This is the cylinder where the partition starts. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>ehhead</i>	This is the head where the partition ends. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>esect</i>	This is the sector where the partition ends. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>ecyl</i>	This is the cylinder where the partition ends. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>rsect</i>	The relative sector from the beginning of the disk where the partition starts. This must be specified and can be used by <code>fdisk</code> to fill in other fields.
<i>numsect</i>	The size in sectors of this disk partition. This must be specified and can be used by <code>fdisk</code> to fill in other fields.

- g
Get the label geometry for disk and display on stdout (see the `-S` option for the format).
- G
Get the physical geometry for disk and display on stdout (see the `-S` option for the format).
- h
Issue verbose message; message will list all options and supply an explanation for each.
- I
Forgo device checks. This is used to generate a file image of what would go on a disk without using the device. Note that you must use `-S` with this option (see above).
- n
Don't update `fdisk` table unless explicitly specified by another option. If no other options are used, `-n` will only write the master boot record to the disk. In addition, note that `fdisk` will not come up in interactive mode if the `-n` option is specified.

fdisk(1M)

- o *offset*
Block offset from start of disk. This option is used for -P, -r, and -w. Zero is assumed when this option is not used.
- P *fill_patt*
Fill disk with pattern *fill_patt*. *fill_patt* can be decimal or hex and is used as number for constant long word pattern. If *fill_patt* is #, then pattern is block # for each block. Pattern is put in each block as long words and fills each block (see -o and -s).
- r
Read from disk and write to stdout. See -o and -s, which specify the starting point and size of the operation.
- R
Treat disk as read-only. This is for testing purposes.
- s *size*
Number of blocks to perform operation on (see -o).
- S *geom_file*
Set the label geometry to the content of the *geom_file*. The *geom_file* contains one specification line. Each line is delimited by a new-line character (\n). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, are separated by white space, and have the following format:

pcyl ncyl acyl bcyl nheads nsectors sectsiz

where the entries have the following values:

pcyl This is the number of physical cylinders for the drive.
ncyl This is the number of usable cylinders for the drive.
acyl This is the number of alt cylinders for the drive.
bcyl This is the number of offset cylinders for the drive (should be zero).

nheads The number of heads for this drive.
nsectors The number of sectors per track.
sectsiz The size in bytes of a sector.
- t
Adjust incorrect slice table entries so that they will not cross partition table boundaries.
- T
Remove incorrect slice table entries that span partition table boundaries.

- v**
Output the HBA (virtual) geometry dimensions. This option must be used in conjunction with the **-w** flag. This option will work for platforms which support virtual geometry. (IA only)
- w**
Write to disk and read from stdin. See **-o** and **-s** , which specify the starting point and size of the operation.
- W -**
Output the disk table to stdout.
- w *fdisk_file***
Create an fdisk file *fdisk_file* from disk table. This can be used with the **-F** option below.

FILES /dev/rdisk/c0t0d0p0 Raw device associated with the fixed disk.
/usr/lib/fs/ufs/mboot Default master boot program.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	IA
Availability	SUNWcsu

SEE ALSO `uname(1)`, `fmthard(1M)`, `prtvtoc(1M)` `attributes(5)`

DIAGNOSTICS Most messages will be self-explanatory. The following may appear immediately after starting the program:

Fdisk: cannot open <device>

This indicates that the device name argument is not valid.

Fdisk: unable to get device parameters for device <device>

This indicates a problem with the configuration of the fixed disk, or an error in the fixed disk driver.

Fdisk: error reading partition table

This indicates that some error occurred when trying initially to read the fixed disk. This could be a problem with the fixed disk controller or driver, or with the configuration of the fixed disk.

Fdisk: error writing boot record

This indicates that some error occurred when trying to write the new partition table out to the fixed disk. This could be a problem with the fixed disk controller, the disk itself, the driver, or the configuration of the fixed disk.

ff(1M)

NAME	ff – list file names and statistics for a file system
SYNOPSIS	ff [-F <i>FSType</i>] [-V] [<i>generic_options</i>] [-o <i>specific_options</i>] <i>special</i> ...
DESCRIPTION	<p>ff prints the pathnames and inode numbers of files in the file system which resides on the special device <i>special</i>. Other information about the files may be printed using options described below. Selection criteria may be used to instruct ff to only print information for certain files. If no selection criteria are specified, information for all files considered will be printed (the default); the -i option may be used to limit files to those whose inodes are specified.</p> <p>Output is sorted in ascending inode number order. The default line produced by ff is:</p> <p><i>path-name</i> i-number</p> <p>The maximum information the command will provide is:</p> <p><i>path-name</i> i-number size uid</p>
OPTIONS	<p>-F Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <i>/etc/vfstab</i> by matching the <i>special</i> with an entry in the table, or by consulting <i>/etc/default/fs</i>.</p> <p>-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from <i>/etc/vfstab</i>. This option may be used to verify and validate the command line.</p> <p><i>generic_options</i> Options that are supported by most <i>FSType</i>-specific modules of the command. The following options are available:</p> <ul style="list-style-type: none">-I Do not print the i-node number after each path name.-l Generate a supplementary list of all path names for multiply-linked files.-p <i>prefix</i> The specified <i>prefix</i> will be added to each generated path name. The default is '.' (dot).-s Print the file size, in bytes, after each path name.

	-u	Print the owner's login name after each path name.				
	-a -n	Select if the file has been accessed in <i>n</i> days.				
	-m -n	Select if the file has been written or created in <i>n</i> days.				
	-c -n	Select if file's status has been changed in <i>n</i> days.				
	-n <i>file</i>	Select if the file has been modified more recently than the argument <i>file</i> .				
	-i <i>i-node-list</i>	Generate names for only those i-nodes specified in <i>i-node-list</i> . <i>i-node-list</i> is a list of numbers separated by commas (with no intervening spaces).				
	-o	Specify <i>FSType</i> -specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the <i>FSType</i> -specific module of the command.				
OPERANDS	<i>special</i>	A special device.				
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>ff</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).					
FILES	<code>/etc/default/fs</code>	default local file system type. Default values can be set for the following flags in <code>/etc/default/fs</code> . For example: <code>LOCAL=ufs</code>				
	<code>LOCAL</code>	The default partition for a command if no <i>FSType</i> is specified.				
	<code>/etc/vfstab</code>	list of default parameters for each file system				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:					
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE					
Availability	SUNWcsu					
SEE ALSO	<code>find(1)</code> , <code>ncheck(1M)</code> , <code>stat(2)</code> , <code>vfstab(4)</code> , <code>attributes(5)</code> , <code>largefile(5)</code> Manual pages for the <i>FSType</i> -specific modules of <code>ff</code> .					
NOTES	This command may not be supported for all <i>FSTypes</i> .					

ff(1M)

The `-a`, `-m`, and `-c` flags examine the `st_atime`, `st_mtime`, and `st_ctime` fields of the `stat` structure respectively. (See `stat(2)`.)

NAME	ffbconfig, SUNWffb_config – configure the FFB Graphics Accelerator
SYNOPSIS	<pre> /usr/sbin/ffbconfig [-dev <i>device-filename</i>] [-res <i>video-mode</i> [now try] [noconfirm nocheck]] [-file machine system] [-deflinear true false] [-defoverlay true false] [-linearorder first last] [-overlayorder first last] [-expvis enable disable] [-sov enable disable] [-maxwids <i>n</i>] [-extovl enable disable] [-g <i>gamma-correction-value</i>] [-gfile <i>gamma-correction-file</i>] [-propt] [-prconf] [-defaults] /usr/sbin/ffbconfig [-propt] [-prconf] /usr/sbin/ffbconfig [-help] [-res ?] </pre>
DESCRIPTION	<p>ffbconfig configures the FFB Graphics Accelerator and some of the X11 window system defaults for FFB.</p> <p>The first form of ffbconfig stores the specified options in the OWconfig file. These options will be used to initialize the FFB device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.</p> <p>The second and third forms of ffbconfig, which invoke only the -prconf, -propt, -help, and -res ? options do not update the OWconfig file. Additionally, for the third form all other options are ignored.</p> <p>Options may be specified for only one FFB device at a time. Specifying options for multiple FFB devices requires multiple invocations of ffbconfig.</p> <p>Only FFB-specific options can be specified through ffbconfig. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line. See the <i>OpenWindows Desktop Reference Manual</i> for details.</p> <p>The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.</p> <p>Both of these standard OWconfig files can only be written by root. Consequently, the ffbconfig program, which is owned by the root user, always runs with setuid root permission.</p>
OPTIONS	<pre> -dev <i>device-filename</i> Specifies the FFB special file. The default is /dev/fbs/ffb0. -file machine system Specifies which OWconfig file to update. If machine, the machine-specific OWconfig file in the /etc/openwin directory tree is used. If system, the global OWconfig file in the /usr/openwin directory tree is used. If the file does not exist, it is created. </pre>

ffbconfig(1M)

`-res video-mode [now | try [noconfirm | nocheck]]`

Specifies the video mode used to drive the monitor connected to the specified FFB device.

video-mode has the format of *widthxheightxrate* where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

The *s* suffix, as in `960x680x112s` and `960x680x108s`, indicates stereo video modes. The *i* suffix, as in `640x480x60i` and `768x575x50i`, indicates interlaced video timing. If absent, non-interlaced timing will be used.

`-res` (the third form in the SYNOPSIS) also accepts formats with @ (at sign) in front of the refresh rate instead of x. `1280x1024@76` is an example of this format.

Some video-modes are supported only on certain revisions of FFB. Also, some video-modes, supported by FFB, may not be supported by the monitor. The list of video-modes supported by the FFB device and the monitor can be obtained by running `ffbconfig` with the `-res ?` option.

The following table lists all possible video modes supported on FFB:

Name	Description
1024x768x60	
1024x768x70	
1024x768x75	
1024x768x77	
1024x800x84	
1152x900x66	
1152x900x76	
1280x800x76	
1280x1024x60	
1280x1024x67	
1280x1024x76	
960x680x112s	(stereo)
960x680x108s	(stereo)
640x480x60	
640x480x60i	(interlaced)

Name	Description
768x575x50i	(interlaced)
1440x900x76	(hi-res)
1600x1000x66	(hi-res)
1600x1000x76i	(hi-res)
1600x1280x76	(hi-res)
1920x1080x72	(hi-res)
1920x1200x70	(hi-res)

Symbolic names

For convenience, some video modes have symbolic names defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

Name	Corresponding Video Mode
svga	1024x768x60
1152	1152x900x76
1280	1280x1024x76
stereo	960x680x112s
ntsc	640x480x60i
pal	768x575x50i
none	(video mode currently programmed in device)

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

now

Specifies that the FFB device will be immediately programmed to display this video mode, in addition to updating the video mode in the `OWconfig` file. This option is useful for changing the video mode before starting the window system.

It is inadvisable to use this suboption with `ffconfig` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `ffconfig` with the `now` suboption, first bring the

ffbconfig(1M)

window system down. If the `now` suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the window system is exited and re-entered. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

`noconfirm`

Instructs `ffbconfig` to bypass confirmation and warning messages and to program the requested video mode anyway.

Using the `-res` option, the user could potentially put the system into an usable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `ffbconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. This option is useful when `ffbconfig` is being run from a shell script.

`nocheck`

Suspends normal error checking based on the monitor sense code. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the FFB device. Note: Use of this option implies `noconfirm` as well.

`try`

Programs the specified video mode on a trial basis. The user will be asked to confirm the video mode by typing `y` within 10 seconds. The user may also terminate the trial before 10 seconds are up by typing any character. Any character other than `y` or RETURN is considered a `no` and the previous video mode will be restored and `ffbconfig` will not change the video mode in the `OWconfig` file and other options specified will still take effect. If a RETURN is pressed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the `now` suboption (see the warning note on the `now` suboption).

`-deflinear true | false`

FFB possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

`-deflinear true` sets the default visual to the linear visual that satisfies other specified default visual selection options. Specifically, the default visual selection options are those set by the Xsun (1) `defdepth` and `defclass` options. See *OpenWindows Desktop Reference Manual* for details.

`-deflinear false` (or if there is no linear visual that satisfies the other default visual selection options) sets the default visual to the non-linear visual as the default.

This option cannot be used when the `-defoverlay` option is present, because FFB does not possess a linear overlay visual.

`-defoverlay true | false`

FFB provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the FFB visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows. This visual has 256 maxwids of opaque color values. See `-maxwids` in `OPTIONS`.

If `-defoverlay` is `true`, the overlay visual will be made the default visual. If `-defoverlay` is `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `defdepth` and `defclass`, will be chosen as the default visual. See the *OpenWindows Desktop Reference Manual* for details.

Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message will be printed and the `-defoverlay` option will be treated as `false`. This option cannot be used when the `-deflinear` option is present, because FFB doesn't possess a linear overlay visual.

`-linearorder first | last`

If `first`, linear visuals will come before their non-linear counterparts on the X11 screen visual list for the FFB screen. If `last`, the nonlinear visuals will come before the linear ones.

`-overlayorder first | last`

If `true`, the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the FFB screen. If `false`, the non-overlay visual will come before the overlay one.

`-expvis enable | disable`

If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor and so forth) can be found in the screen visual list.

`-sov enable | disable`

Advertises the root window's `SERVER_OVERLAY_VISUALS` property. SOV visuals will be exported and their transparent types, values and layers can be retrieved through this property. If `-sov disable` is specified, the `SERVER_OVERLAY_VISUALS` property will not be defined. SOV visuals will not be exported.

`-maxwids n`

Specifies the maximum number of FFB X channel pixel values that are reserved for use as window sIDs (WIDs). The remainder of the pixel values in overlay colormaps are used for normal X11 opaque color pixels. The reserved WIDs are allocated on a first-come first-serve basis by 3D graphics windows (such as XGL), MBX windows, and windows that have a non-default visual. The X channel codes 0 to $(255-n)$ will be opaque color pixels. The X channel codes $(255-n+1)$ to 255 will be reserved for use as WIDs. Legal values on FFB, FFB2 are: 1, 2, 4, 8, 16, and 32. Legal values on FFB2+ are: 1, 2, 4, 8, 16, 32, and 64.

ffbconfig(1M)

`-extovl enable | disable`

This option is available only on FFB2+. If enabled, extended overlay is available. The overlay visuals will have 256 opaque colors. The SOV visuals will have 255 opaque colors and 1 transparent color. This option enables hardware supported transparency which provides better performance for windows using the SOV visuals.

`-g gamma-correction value`

This option is available only on FFB2+. This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by `XSolarisGetVisualGamma(3)`. See `XSolarisGetVisualGamma(3)` for a description of that function.

This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.

`-gfile gamma-correction file`

This option is available only on FFB2+. This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each line. This file should provide 256 triplet values, each in hexadecimal format and separated by at least 1 space. Following is an example of this file:

```
0x00 0x00 0x00
0x01 0x01 0x01
0x02 0x02 0x02
...
...
0xff 0xff 0xff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note, when gamma correction is being done using user specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

`-defaults`

Resets all option values to their default values.

`-propt`

Prints the current values of all FFB options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the OWconfig file after the call to `ffbconfig` completes. The following is a typical display using the `-propt` option:

```
--- OpenWindows Configuration for /dev/fbs/ffb0 ---
OWconfig: machine
Video Mode: NONE
```

```

Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
                  Overlay Visuals are last
OpenGL Visuals: disabled
SOV: disabled
Allocated WIDs: 32
    
```

-prconf

Prints the FFB hardware configuration. The following is a typical display using the `-prconf` option:

```

--- Hardware Configuration for /dev/fbs/ffb0 ---
Type: double-buffered FFB2 with Z-buffer
Board: rev x
PROM Information: @(#)ffb2.fth x.x xx/xx/xx
FBC: version x
DAC: Brooktree 9068, version x
3DRAM: Mitsubishi 1309, version x
EDID Data: Available - EDID version 1 revision x
Monitor Sense ID: 4 (Sun 37x29cm RGB color monitor)
Monitor possible resolutions: 1024x768x60, 1024x768x70,
                              1024x768x75, 1152x900x66, 1152x900x76,
                              1280x1024x67, 1280x1024x76, 960x680x112s,
                              640x480x60
Current resolution setting: 1280x1024x76
    
```

-help

Prints a list of the `ffbconfig` command line options, along with a brief explanation of each.

DEFAULTS

For a given invocation of `ffbconfig` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value.

When the window system is run, if an FFB option has never been specified via `ffbconfig`, a default value is used. The option defaults are listed in the following table:

Option	Default
<code>-dev</code>	<code>/dev/fbs/ffb0</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-deflinear</code>	<code>false</code>
<code>-defoverlay</code>	<code>false</code>
<code>-linearorder</code>	<code>last</code>

ffbconfig(1M)

Option	Default
-overlayorder	last
-expvis	enabled
-sov	enabled
-maxwids	32

The default for the `-res` option of none means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default FFB video mode.

EXAMPLES **EXAMPLE 1** Changing The Monitor Type

The following example switches the monitor type to the resolution of 1280 × 1024 at 76 Hz:

```
example% /usr/sbin/ffbconfig -res 1280x1024x76
```

firmware(1M)

NAME	firmware – bootable firmware programs and firmware commands				
DESCRIPTION	<p>Between the time most computers are turned on and the boot program is loaded to bootstrap the machine, the computer is in an operating state known as the firmware state. In the firmware state, a small program in non-volatile memory is running on the machine, and the user can perform certain system operations usually unavailable from single- or multi-user operating states.</p> <p>There are two basic kinds of firmware operations: running firmward commands and running bootable programs.</p> <table border="0"><tr><td>Running firmware commands</td><td>These commands include commands for displaying the Equipped Device Table, performing a system memory dump, displaying the firmware version, creating a floppy key, and so forth. These commands are executed by the firmware program.</td></tr><tr><td>Running bootable programs</td><td>These programs include the operating system and other bootable programs (for example, a program to fill the Equipped Device Table). These programs are located in the <code>/stand</code> file system. When a bootable program is requested from firmware, the firmware program loads and executes the program, passing control of the system to the bootable program.</td></tr></table> <p>Some firmware programs, allow you to request the configuration of a new bootable operating system from firmware by specifying the name of a configuration file (usually <code>/stand/system</code>) as the name of the program to boot; see <code>system(4)</code>.</p> <p>See the hardware guide that accompanies your computer for descriptions of the firmware commands and programs available with your machine.</p>	Running firmware commands	These commands include commands for displaying the Equipped Device Table, performing a system memory dump, displaying the firmware version, creating a floppy key, and so forth. These commands are executed by the firmware program.	Running bootable programs	These programs include the operating system and other bootable programs (for example, a program to fill the Equipped Device Table). These programs are located in the <code>/stand</code> file system. When a bootable program is requested from firmware, the firmware program loads and executes the program, passing control of the system to the bootable program.
Running firmware commands	These commands include commands for displaying the Equipped Device Table, performing a system memory dump, displaying the firmware version, creating a floppy key, and so forth. These commands are executed by the firmware program.				
Running bootable programs	These programs include the operating system and other bootable programs (for example, a program to fill the Equipped Device Table). These programs are located in the <code>/stand</code> file system. When a bootable program is requested from firmware, the firmware program loads and executes the program, passing control of the system to the bootable program.

SEE ALSO	<p><code>system(4)</code>, <code>attributes(5)</code></p> <p><i>Writing FCode 3.x Programs</i></p> <p><i>OpenBoot 2.x Command Reference Manual</i></p>				

WARNINGS | The firmware program typically does not know if a requested program is bootable or not; requesting a program that is not bootable from firmware can lead to unpredictable results.

flar(1M)

NAME	flar – administer flash archives						
SYNOPSIS	flar -i [-l] [-k <i>keyword</i>] [-t [-p <i>posn</i>] [-b <i>blocksize</i>]] <i>archive</i> flar -c [-d <i>dir</i>] [-u <i>section</i>] [-t [-p <i>posn</i>] [-b <i>blocksize</i>]] <i>archive</i> flar -s [-d <i>dir</i>] [-u <i>section</i>] [-f] [-S <i>section</i>] [-t [-p <i>posn</i>] [-b <i>blocksize</i>]] <i>archive</i>						
DESCRIPTION	<p>The flar command is used to administer flash archives. A flash archive is an easily transportable version of a reference configuration of the Solaris operating environment, plus optional other software. Such an archive is used for the rapid installation of Solaris on large numbers of machines.</p> <p>The flar command includes subcommands for extracting information, splitting archives, and combining them. Subcommands are indicated by the first option in a flar command line. These options are as follows:</p> <ul style="list-style-type: none">-c Combine the individual sections that make up an archive into the archive. If <i>dir</i> is specified (see -d option below), the sections will be gathered from <i>dir</i>; otherwise, they will be gathered from the current directory. Each section is assumed to be in a separate file, the names of which are the section names. At a minimum, the archive cookie (<i>cookie</i>), archive identification (<i>identification</i>), and archive files (<i>archive</i>) sections must be present. If <i>archive</i> is a directory, its contents are archived using cpio prior to inclusion in the archive. If so specified in the <i>identification</i> section, the contents are compressed. <p>Note that no validation is performed on any of the sections. In particular, no fields in the <i>identification</i> section are validated or updated. See flash_archive(4) for a description of the archive sections.</p> <ul style="list-style-type: none">-i Extract information on an archive. This subcommand is analogous to pkginfo.-s Split an archive into one file for each section of the archive. Each section is copied into a separate file in <i>dir</i>, if <i>dir</i> is specified (see -d option below), or the current directory if it is not. The files resulting from the split are named after the sections. The archive cookie is stored in a file named <i>cookie</i>. If <i>section</i> is specified (see -u option below), only the named section is copied. <p>The options for each subcommand are described below.</p>						
OPTIONS	<p>The options for flar -i (extract info) subcommand are as follows:</p> <table><tr><td>-k <i>keyword</i></td><td>Only the value of the keyword <i>keyword</i> is returned.</td></tr><tr><td>-l</td><td>List all files in the archive. Does not process content from any sections other than the <i>archive</i> section.</td></tr></table> <p>The following are flar -i options used with tape archives:</p> <table><tr><td>-b <i>blocksize</i></td><td>The block size to be used when creating the archive. If not specified, a default block size of 64K is used.</td></tr></table>	-k <i>keyword</i>	Only the value of the keyword <i>keyword</i> is returned.	-l	List all files in the archive. Does not process content from any sections other than the <i>archive</i> section.	-b <i>blocksize</i>	The block size to be used when creating the archive. If not specified, a default block size of 64K is used.
-k <i>keyword</i>	Only the value of the keyword <i>keyword</i> is returned.						
-l	List all files in the archive. Does not process content from any sections other than the <i>archive</i> section.						
-b <i>blocksize</i>	The block size to be used when creating the archive. If not specified, a default block size of 64K is used.						

- p *posn* Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is examined.
- t The archive to be analyzed is located on a tape device. The path to the device is specified by *outfile* (see OPERANDS).

The options for `flar -s` and `-c` (split and combine archives) subcommands are as follows:

- d *dir* Retrieve sections from *dir*, rather than from the current directory.
- f (Used with `-s` only.) Extract the *archive* section into directory called *archive*, rather than placing it in a file of the same name as the section.
- S *section* (Used with `-s` only.) Extract only the section named *section* from the archive.
- u *section* Appends *section* to the list of sections to be included. The default list includes the *cookie*, *identification*, and *archive* sections. *section* can be a single section name or a space-separated list of section names.

The following options are used with tape archives (with both `-c` and `-s`):

- b *blocksize* The block size to be used when creating the archive. If not specified, a default block size of 64K is used.
- p *posn* Used only with `-t`. Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is used.
- t Create an archive on or read an archive from a tape device. The *outfile* operand (see OPERANDS) is assumed to be the name of the tape device.

OPERANDS The following operand is supported:

- outfile* Path to tape device if the `-t` option was used. Otherwise, the path to a flash archive.

EXIT STATUS The following exit values are returned for the `-c` and `-s` subcommands:

- 0 Successful completion.
- >0 An error occurred.

The following exit values are returned for the `-i` subcommand:

- 0 Successful completion.
- 1 Command failed. If the `-k` option is used and the requested keyword is not found, `flar` returns 2.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

flar(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWinst

SEE ALSO flarcreate(1M), flash_archive(4), attributes(5)

NAME	flarcreate – create a flash archive from a master system
SYNOPSIS	flarcreate -n <i>name</i> [-R <i>root</i>] [-S] [-H] [-c] [-x <i>exclude</i>] [-t [-p <i>posn</i>] [-b <i>blocksize</i>]] [-i <i>date</i>] [-m <i>master</i>] [-u <i>section</i> ... [-d <i>dir</i>]] [-U <i>key=val</i> ...] [-f [<i>filelist</i> -] [-F]] [-a <i>author</i>] [-e <i>descr</i> -E <i>descr_file</i>] [-T <i>type</i>] <i>outfile</i>
DESCRIPTION	<p>The <code>flarcreate</code> command creates a flash archive from a master system. A master system is one that contains a reference configuration, which is a particular configuration of the Solaris operating environment, plus optional other software. A flash archive is an easily transportable version of the reference configuration.</p> <p>You can run <code>flarcreate</code> in multi- or single-user mode. You can also use the command when the master system is booted from the first Solaris software CD or from a Solaris net image.</p> <p>Archive creation should be performed when the master system is in as stable a state as possible.</p> <p>See <code>flash_archive(4)</code> for a description of the flash archive.</p>
OPTIONS	<p>The <code>flarcreate</code> command has the following general options:</p> <ul style="list-style-type: none"> -c Compress the archive using <code>compress(1)</code> -f <i>filelist</i> Use the contents of <i>filelist</i> as a list of files to include in the archive. The files are included in addition to the normal file list, unless -F is specified (see below). If <i>filelist</i> is -, the list is taken from standard input. -F Include only files in the list specified by -f. This option makes -f <i>filelist</i> an absolute list, rather than a list that is appended to the normal file list. -H Do not generate hash identifier. -R <i>root</i> Create the archive from the filesystem tree rooted at <i>root</i>. If you do not specify this option, <code>flarcreate</code> creates an archive from a filesystem rooted at /. -S Do not include sizing information in the archive. -U <i>key=val...</i> Include the user-defined keyword(s) and values in the archive identification section -x <i>exclude</i> Exclude the directory <i>exclude</i> from the archive. Note that the <i>exclude</i> directory is assumed to be relative to the alternate root specified using -R. <p>Use the following options with user-defined sections.</p> <ul style="list-style-type: none"> -d <i>dir</i> Retrieve the section file specified with -u from <i>dir</i>.

flarcreate(1M)

-u *section* ... Included the user-defined section located in the file *section* in the archive. *section* must be a blank-separated list of section names as described in flar(1M).

Use the following options with tape archives.

-b *blocksize* The block size to be used when creating the archive. If not specified, a default block size of 64K is used.

-p *posn* Used only with -t. Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is used.

-t Create an archive on a tape device. The *outfile* operand (see OPERANDS) is assumed to be the name of the tape device.

The following options are used for archive identification.

-a *author* *author* is used to provide an author name for the archive identification section. If you do not specify -a, no author name is included in the identification section.

-e *descr* The description to be included in the archive as the value of the *content_description* archive identification key. This option is incompatible with -E.

-E *descr_file* The description to be used as the value of the archive identification *content_description* key is retrieved from the file *descr_file*. This option is incompatible with -e.

-i *date* By default, the value for the *creation_date* field in the identification section is generated automatically, based on the current system time and date. If you specify the -i option, *date* is used instead.

-m *master* By default, the value for the *creation_master* field in the identification section is the name of the system on which you run flarcreate, as reported by `uname -n`. If you specify -m, *master* is used instead.

-n *name* This option is required if you are using flarcreate for archive identification. The value of *name* is used to identify the archive. It is also used as the value of the *content_name* archive identification flag.

-T *type* Content type included in the archive as the value of the *content_type* archive identification key. If you do not specify -T, the *content_type* keyword is not included.

OPERANDS The following operands are supported:

outfile Name of the tape device if the -t option is used.
Otherwise, the path to the flash archive.

flarcreate(1M)

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

fmthard(1M)

NAME	fmthard – populate VTOC on hard disks
SPARC	fmthard -d <i>data</i> -n <i>volume_name</i> -s <i>datafile</i> [-i] /dev/rdisk/c? [t?] d?s2
IA	fmthard -d <i>data</i> -n <i>volume_name</i> -s <i>datafile</i> [-i] [-p <i>pboot</i>] [-b <i>bootblk</i>] /dev/rdisk/c? [t?] d?s2
DESCRIPTION	<p>The <code>fmthard</code> command updates the VTOC (Volume Table of Contents) on hard disks and, on IA systems, adds boot information to the Solaris <code>fdisk</code> partition. One or more of the options <code>-s datafile</code>, <code>-d data</code>, or <code>-n volume_name</code> must be used to request modifications to the disk label. To print disk label contents, see <code>prtvtoc(1M)</code>. The <code>/dev/rdisk/c?[t?]d ?s2</code> file must be the character special file of the device where the new VTOC is to be installed. On IA systems, <code>fdisk(1M)</code> must be run on the drive before <code>fmthard</code>.</p> <p>If you are using an IA system, note that the term “partition” in this page refers to <i>slices</i> within the IA <code>fdisk</code> partition on IA machines. Do not confuse the partitions created by <code>fmthard</code> with the partitions created by <code>fdisk</code>.</p>
OPTIONS	<p>The following options apply to <code>fmthard</code>:</p> <p><code>-i</code> This option allows the command to create the desired VTOC table, but prints the information to standard output instead of modifying the VTOC on the disk.</p> <p><code>-d data</code> The <i>data</i> argument of this option is a string representing the information for a particular partition in the current VTOC. The string must be of the format <i>part:tag:flag:start:size</i> where <i>part</i> is the partition number, <i>tag</i> is the ID TAG of the partition, <i>flag</i> is the set of permission flags, <i>start</i> is the starting sector number of the partition, and <i>size</i> is the number of sectors in the partition. See the description of the <i>datafile</i> below for more information on these fields.</p> <p><code>-n volume_name</code> This option is used to give the disk a <i>volume_name</i> up to 8 characters long.</p> <p><code>-s datafile</code> This option is used to populate the VTOC according to a <i>datafile</i> created by the user. If the <i>datafile</i> is “-”, <code>fmthard</code> reads from standard input. The <i>datafile</i> format is described below. This option causes all of the disk partition timestamp fields to be set to zero.</p> <p>Every VTOC generated by <code>fmthard</code> will also have partition 2, by convention, that corresponds to the whole disk. If the input in <i>datafile</i> does not specify an entry for partition 2, a default partition 2 entry will be created automatically in VTOC with the tag <code>V_BACKUP</code> and size equal to the full size of the disk.</p>

The *datafile* contains one specification line for each partition, starting with partition 0. Each line is delimited by a new-line character (\n). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, separated by "white space" and having the following format:

```
partition tag flag starting_sector size_in_sectors
```

where the entries have the following values.

<i>partition</i>	The partition number. Currently, for Solaris SPARC, a disk can have up to 8 partitions, 0–7. Even though the <i>partition</i> field has 4 bits, only 3 bits are currently used. For IA, all 4 bits are used to allow slices 0–15. Each Solaris <i>fdisk</i> partition can have up to 16 slices.
<i>tag</i>	The partition tag: a decimal number. The following are reserved codes: 0 (V_UNASSIGNED), 1 (V_BOOT), 2 (V_ROOT), 3 (V_SWAP), 4 (V_USR), 5 (V_BACKUP), 6 (V_STAND), 7 (V_VAR), and 8 (V_HOME).
<i>flag</i>	The flag allows a partition to be flagged as unmountable or read only, the masks being: V_UNMNT 0x01, and V_RDONLY 0x10. For mountable partitions use 0x00.
<i>starting_sector</i>	The sector number (decimal) on which the partition starts.
<i>size_in_sectors</i>	The number (decimal) of sectors occupied by the partition.

Note that you can save the output of a `prtvtoc` command to a file, edit the file, and use it as the *datafile* argument to the `-s` option.

IA Options

The functionality provided by the following two IA options is also provided by `installboot(1M)`. Because the functionality described here may be removed in future versions of `fmthard`, you should use `installboot` to install boot records. The following options currently apply to `fmthard`:

<code>-p <i>pboot</i></code>	This option allows the user to override the default partition boot file, <code>/usr/platform/<i>platform-name</i>/lib/fs/ufs/<i>pboot</i></code> . The partition boot file is platform dependent, where <i>platform-name</i> can be determined using the <code>-i</code> option to <code>uname(1)</code> .
<code>-b <i>bootblk</i></code>	This option allows the user to override the default <i>bootblk</i> file, <code>/usr/platform/<i>platform-name</i>/lib/fs/ufs/<i>bootblk</i></code> . The boot block file is platform dependent, where <i>platform-name</i> can be determined using the <code>-i</code> option to <code>uname(1)</code> .

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

fmthard(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `uname(1)`, `format(1M)`, `prtvtoc(1M)`, `attributes(5)`

IA Only `fdisk(1M)`, `installboot(1M)`

NOTES Special care should be exercised when overwriting an existing VTOC, as incorrect entries could result in current data being inaccessible. As a precaution, save the old VTOC.

`fmthard` cannot write a disk label on an unlabeled disk. Use `format(1M)` for this purpose.

NAME	fncheck – check for consistency between FNS data and NIS+ data				
SYNOPSIS	fncheck [-r] [-s] [-u] [-t <i>type</i>] [<i>domain_name</i>]				
DESCRIPTION	<p>fncheck is used for checking for inconsistencies between FNS username or hostname contexts and the contents of the corresponding NIS+ <i>passwd.org_dir</i> or <i>hosts.org_dir</i> tables, respectively, in the NIS+ domain <i>domain_name</i>. If <i>domain_name</i> is omitted, the domain name of the current machine is used. By default (in the absence of the -r and -s options), the following inconsistencies are displayed:</p> <ul style="list-style-type: none"> ■ items that appear only in the FNS context but do not appear in the NIS+ table, ■ items that appear only in the NIS+ table but do not appear in the FNS context. 				
OPTIONS	<p>-r Display only items that appear in the FNS context but do not appear in the corresponding NIS+ table.</p> <p>-s Display items that appear in the NIS+ table but do not appear in the corresponding FNS context.</p> <p>-u Update the FNS context based on information in the corresponding NIS+ table. If the -r option is used, items that appear only in the FNS context are removed from the FNS context. If the -s option is used, items that appear only in the NIS+ table are added to the FNS context. If neither -r or -s are specified, items are added and removed from the FNS context to make it consistent with the corresponding NIS+ table.</p> <p>-t <i>type</i> Specify the type of context to check. <i>type</i> can be either <i>hostname</i> or <i>username</i>. If this option is omitted, both <i>hostname</i> and <i>username</i> contexts are checked. If <i>type</i> is <i>hostname</i>, the FNS <i>hostname</i> context is checked against the NIS+ <i>hosts.org_dir</i> table. If <i>type</i> is <i>username</i>, the FNS <i>username</i> context is checked against the NIS+ <i>passwd.org_dir</i> table.</p>				
USAGE	Although fncheck can be used to add users and hosts to the username and hostname contexts as new users and hosts are added to NIS+, that is not its intended purpose. fncheck is an expensive operation because it makes complete comparisons of the NIS+ table and the corresponding FNS context. When a user or host is added or removed from NIS+ using <i>admintool</i> (see <i>admintool</i> (1M)), it automatically updates the appropriate FNS contexts.				
ATTRIBUTES	See <i>attributes</i> (5) for descriptions of the following attributes:

fnccopy(1M)

NAME	fnccopy – copy FNS contexts, possibly from one naming service to another naming service
SYNOPSIS	fnccopy [-f <i>filename</i>] [-i <i>old-naming-service</i>] [-o <i>new-naming-service</i>] <i>old-fns-context</i> <i>new-fns-context</i>
DESCRIPTION	<p>fnccopy copies recursively the FNS context, <i>old-fns-context</i>, and attributes to a new FNS context, <i>new-fns-context</i>. If -i and -o options are specified with the respective naming service, the <i>old-fns-context</i> will be resolved using <i>old-naming-service</i> as the underlying naming service, and <i>new-fns-context</i> will be created using <i>new-naming-service</i> as the underlying naming service. In the absence of -i and -o options, the default naming service will be used (see fnselect(1M)).</p> <p>When the -f option is used, <i>filename</i> names a file containing a list of contexts in the <i>old-fns-context</i> that should be copied to the <i>new-fns-context</i>.</p> <p>If the FNS context <i>new-fns-context</i> already exists in the target naming service, <i>new-naming-service</i>, this command will copy only the contexts and bindings that do not exist in the target naming service. This command will not over-write any of the existing FNS contexts in the target naming service.</p> <p>This command follows links and copies FNS contexts and binding to the <i>new-fns-context</i> namespace.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-f <i>filename</i> Specifies a file name that contains a list of FNS contexts to be copied.-i <i>old-naming-service</i> Specifies the source naming service; currently only nis is supported.-o <i>new-naming-service</i> Specifies the target naming service; currently only nisplus is supported.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"><i>new-fns-context</i> The new FNS context.<i>old-fns-context</i> The current FNS context.
EXAMPLES	<p>EXAMPLE 1 Copying the fnccopy FNS Printer Context</p> <p>The following command copies the FNS printer context .../fed-naming.eng.sun.com/service/printer and its subcontexts and bindings to the FNS printer context .../sun.com/orgunit/ssi.eng/service/printer.</p> <pre>% fnccopy .../fed-naming.eng.sun.com/service/printer \ .../sun.com/orgunit/ssi.eng/service/printer</pre>

EXAMPLE 2 Copying the NIS FNS Users' Contexts

The following command copies the NIS FNS users' contexts specified in the file `/etc/ssi-users-list` to NIS+ FNS users' context of the orgunit `ssi.eng`:

```
% fncopy -i nis -o nisplus -f /etc/ssi-users-list \
    thisorgunit/user org/ssi.eng/user
```

EXIT STATUS

0 Operation was successful.

1 Operation failed.

fncreate(1M)

NAME	fncreate – create an FNS context
SYNOPSIS	fncreate -t <i>context_type</i> [-Dosv] [-f <i>input_file</i>] [-r <i>reference_type</i>] <i>composite_name</i>
DESCRIPTION	<p>fncreate creates an FNS context of type <i>context_type</i>, where a <i>context_type</i> must be one of <i>org</i>, <i>hostname</i>, <i>host</i>, <i>username</i>, <i>user</i>, <i>service</i>, <i>fs</i>, <i>site</i>, <i>nsid</i>, or <i>generic</i>. It takes as the last argument a composite name, <i>composite_name</i>, for the context to be created. In addition to creating the context named, fncreate also creates subcontexts of the named context using FNS Policies of what types of contexts should be bound in those contexts. See <i>fns_policies(5)</i>.</p> <p>fncreate discovers which naming service is in use and creates contexts in the appropriate naming service. When FNS is being initially set up, it will by default create contexts for NIS+. This default can be changed by the use of <i>fnselect(1M)</i> to explicitly select a naming service.</p> <p>When using FNS for a NIS+ environment, fncreate creates NIS+ tables and directories in the NIS+ hierarchy. See <i>fns_nis+(5)</i> for more information on the necessary NIS+ credentials and the use of the environment variable <i>NIS_GROUP</i> when using fncreate and other FNS commands.</p> <p>When using FNS for a NIS environment, fncreate creates NIS maps and hence must be executed as superuser on the NIS master of the FNS-related maps. See <i>fns_nis(5)</i> for more information specific to the use of FNS in a NIS environment.</p> <p>When using FNS for an environment that uses <i>/etc</i> files for its naming information, fncreate creates files in the <i>/var/fn</i> directory. See <i>fns_files(5)</i> for more information specific to the use of FNS for files.</p>
OPTIONS	<p>The following options are supported:</p> <p>-D Information about the creation of a context, and corresponding NIS+ directories and tables, or NIS maps, or files entry, is displayed as each context is created.</p> <p>-f <i>input_file</i> Create a context for every user or host listed in <i>input_file</i>. This option is only applicable when used with the -t <i>username</i> or -t <i>hostname</i> options. The format of the file is an atomic user name or host name per line. This option is used to create contexts for a subset of the <i>users/hosts</i> found in the corresponding <i>passwd</i> or <i>hosts</i> database of the naming service (that is, for NIS+ these are the <i>passwd.org_dir</i> or <i>hosts.org_dir</i> tables, respectively). If this option is omitted, fncreate creates a context for every <i>user/host</i> found in the corresponding <i>passwd</i> or <i>hosts</i> database.</p>

fncreate(1M)

-o

Only the context named by *composite_name* is created; no subcontexts are created. When this option is omitted, subcontexts are created according to the FNS Policies for the type of the new object.

-t *context_type*

The following are valid entries for *context_type*:

org

Create organization context, and default subcontexts, for an existing NIS+ domain, NIS domain, or /etc files environment.

For NIS+, *composite_name* is of the form *org/domain/* where *domain* is a NIS+ domain. An empty domain name indicates the creation of the organization context for the root NIS+ domain; otherwise, the domain name names the corresponding NIS+ domain. *domain* can be either the fully-qualified NIS+ domain name — dot ('.')-terminated — or the NIS+ domain name named relative to the NIS+ root domain.

For example, the following creates the root organization context and its subcontexts for the NIS+ root domain *Wiz.Com.*:

```
eg% fncreate -t org org//
```

The same thing could have been achieved using the following command:

```
eg% fncreate -t org org/Wiz.COM./
```

Typically, this is the first FNS context created.

To create the organization context for a subdomain of *Wiz.COM.*, execute either of the following commands:

```
eg% fncreate -t org org/sales/
```

or

```
eg% fncreate -t org \  
org/sales.Wiz.COM./
```

Note that if the corresponding NIS+ domain does not exist, *fncreate* fails. See *nissetup(1M)* for setting up a NIS+ domain.

A *ctx_dir* directory is created under the directory of the organization named.

fncreate(1M)

For NIS or an `/etc` files environment, *domain* should be NULL (empty) because NIS and `/etc` files do not support a hierarchy namespace of domains. For example, the following command creates the organization context for the NIS or `/etc` files environment:

```
eg% fncreate -t org org//
```

For NIS+, NIS, and `/etc` files, creating the organization context also creates the organization's immediate subcontexts `host`, `user`, and `service` and their subcontexts. This includes a context for every host entry in the corresponding hosts database of the naming service (that is, `hosts.org_dir` NIS+ table, or `hosts` NIS map, or `/etc/hosts` file), and a context for every user entry in the `passwd` database of the naming service (that is, `passwd.org_dir` NIS+ table, or `passwd` NIS map, or `/etc/passwd` file) unless the option `-o` is specified. Bindings for these subcontexts are recorded under the organization context.

hostname

Create a hostname context in which atomic host names can be bound, and bind the reference of the context to *composite_name*. If the suffix of *composite_name* is `host/`, the hostname context created is also bound to the composite name with this suffix replaced by `_host/`, and the reverse (that is, if a composite name with a `_host/` suffix was supplied, a binding would be created for `host/`). Also create a host context for every host entry in the corresponding hosts database of the naming service (`hosts.org_dir` NIS+ table, or `hosts` NIS map, or `/etc/hosts` file), unless either option `-o` or `-f` is specified. The following example creates host contexts for all hosts in the `sales` organization:

```
eg% fncreate -t hostname \  
org/sales/host/
```

Typically, a hostname context need not be created explicitly since it is created by default, as a subcontext under `org`.

host

Create a host context for a specific host, and its `service` and `fs` subcontexts, and bind the reference of the context to *composite_name*. For

example, the following creates a host context and `service` and `fs` subcontexts for host `sylvan`:

```
eg% fncreate -t host \
org/sales/host/sylvan/
```

username

Create a username context in which atomic user names can be bound, and bind the reference of the context to *composite_name*. If the suffix of *composite_name* is `user/`, the username context created is also bound to the composite name with this suffix replaced by `_user/`, and the reverse. Also create a user context for every user entry in the corresponding `passwd` database of the naming service (that is, `passwd.org_dir` NIS+ table, or `passwd` NIS map, or `/etc/passwd` file), unless either the option `-o` or `-f` is specified. The following example creates username contexts for all users in the `sales` organization:

```
eg% fncreate -t username \
org/sales/user/
```

Typically, a username context need not be created explicitly since it is created by default, as a subcontext under `org`.

user

Create a user context for a specific user, and its `service` and `fs` subcontexts, and bind the reference of the context to *composite_name*. For example, the following creates a user context and `service` and `fs` subcontexts for user `jsmith`:

```
eg% fncreate -t user \
org/sales/user/jsmith/
```

service

Create a service context in which slash-separated left-to-right service names can be bound, and bind the reference of the context to *composite_name*. If the suffix of *composite_name* is `service/`, the service context created is also bound to the composite name with this suffix replaced by `_service/`, and the reverse. Typically, a service context need not be created explicitly since it is created by default, as a subcontext under `org`, `host`, or `user` contexts.

fs

Create a file system context for a user or host, and bind the reference of the context to *composite_name*.

fncreate(1M)

The composite name must be the name of a host or a user, with either `fs/` or `_fs/` appended to it. If the suffix of *composite_name* is `fs/`, the file system context created is also bound to the composite name with this suffix replaced by `_fs/`, and the reverse.

Typically, a file system context need not be created explicitly since it is created by default, as a subcontext of a user or host context.

The file system context of a user is the user's home directory as stored in the `passwd` database of the naming service (that is, in NIS+ table `passwd.org_dir`, or `passwd` NIS map, or `/etc/passwd` file). The file system context of a host is the set of NFS file systems that the host exports.

Use the `fncreate_fs(1M)` command to create file system contexts for organizations and sites, or to create file system contexts other than the defaults for users and hosts.

site

Create a site context in which dot-separated right-to-left site names can be bound, and a service subcontext, and bind the reference of the context to *composite_name*. If the suffix of *composite_name* is `site/`, the hostname context created is also bound to the composite name with this suffix replaced by `_site/`, and the reverse. Typically, a `site` context is created at the same level as the `org` context and is used for creating a geographical namespace that complements the organizational namespace of an enterprise.

nsid

Create a context in which namespace identifiers can be bound. This context has a flat namespace, in which only atomic names can be bound. An example of such a context is the context to which the name `site/east/` is bound. This context can have the following bindings: `site/east/host`, `site/east/user`, and `site/east/service`.

generic

Create a generic context in which slash-separated left-to-right names can be bound, and bind the reference of the context to *composite_name*. The option `-r` can be used to specify the reference type

fncreate(1M)

to be associated with the context. If the `-r` option is omitted, the reference type used is the reference type of the parent context if the parent context is a generic context; otherwise, the reference type is `onc_fn_generic`.

- `-r reference_type` Use *reference_type* as the reference type of the generic context being created. This option can be used only with the `-t generic` option.
- `-s` Create the context and bind it in to supercede any existing binding associated with *composite_name*. If this option is omitted, `fncreate` fails if *composite_name* is already bound.
- `-v` Information about the creation of a context is displayed as each context is created.

OPERANDS The following operand is supported:

composite_name An FNS named object.

EXAMPLES **EXAMPLE 1** Creating A Host Context

This example illustrates the creation of a host context in the root organization and a user context in a sub-organization.

The following command creates a context, and subcontexts, for the root organization:

```
% fncreate -t org org//
```

It causes the following commands to be invoked automatically:

```
% fncreate -t service org//service/  
% fncreate -t hostname org//host/  
% fncreate -t username org//user/
```

The following command creates a context, and subcontexts, for host `sylvan`:

```
% fncreate -t host org//host/sylvan/
```

It causes the following commands to be invoked automatically:

```
% fncreate -t service org//host/sylvan/service/  
eg% fncreate -t fs org//host/sylvan/fs/
```

The following command creates a context, and subcontexts, associated with a sub-organization `dct`:

```
% fncreate -t org org/dct/
```

It causes the following commands to be invoked automatically:

fncreate(1M)

EXAMPLE 1 Creating A Host Context (Continued)

```
% fncreate -t service org/dct/service/  
% fncreate -t hostname org/dct/host/  
% fncreate -t username org/dct/user/
```

The following command creates a context, and subcontexts, for user msmith:

```
% fncreate -t user org/dct/user/msmith/
```

It causes the following commands to be invoked automatically:

```
% fncreate -t service org/dct/user/msmith/service/  
% fncreate -t fs org/dct/user/msmith/fs/
```

The following commands create service contexts:

```
% fncreate -t service org/dct/service/fax  
% fncreate -t service org/dct/service/fax/classA
```

EXIT STATUS

0	Operation was successful.
1	Operation failed.

NAME	fncreate_fs – create FNS file system contexts
SYNOPSIS	<pre>fncreate_fs [-r] [-v] -f input_file composite_name fncreate_fs [-r] [-v] composite_name [mount_options] [mount_location...]</pre>
DESCRIPTION	The <code>fncreate_fs</code> command creates or updates the FNS file system context named by <i>composite_name</i> . A description of the context's bindings is provided in <i>input_file</i> if the first form of the command is used, or is given on the command line if the second form is used.
OPTIONS	<pre>-r Replace the bindings in the context named by <i>composite_name</i> with only those specified in the input. This is equivalent to destroying the context (and, recursively, its subcontexts), and then running <code>fncreate_fs</code> without this option. This option should be used with care. -v Verbose. Display information about the contexts being created and modified. -f input_file Read input from <i>input_file</i>. If <i>input_file</i> is '-' (hyphen), read from standard input instead.</pre>
OPERANDS	The following operand is supported: <i>composite_name</i> An FNS named object.
USAGE	The <code>fncreate_fs</code> command populates the file system portions of the FNS namespace. The automounter (see <code>automount(1M)</code>) will then "mount" the FNS namespace under <code>/xfn</code> . The directory with the FNS name <code>org/engineering/fs</code> , for example, can be found on the file system as <code>/xfn/org/engineering/fs</code> . The format of the input to <code>fncreate_fs</code> is similar, but not identical, to the format of indirect automount maps. Differences are enumerated in the NOTES section below.
Input File Format	The input file supplies the names and values to be bound in the context of <i>composite_name</i> . Its format is a sequence of lines of the form: <i>name</i> [<i>-options</i>] [<i>location</i> . . .] For each such entry, a reference to the <i>location</i> (s) and the corresponding <i>options</i> is bound to the name <i>composite_name/name</i> . The <i>name</i> field may be a simple atomic name, a slash-separated hierarchical name, or '.' (period). If it is '.' then the reference is bound directly to <i>composite_name</i> . The <i>name</i> field must not begin with a slash. The <i>location</i> field specifies the host or hosts that serve the files for <i>composite_name/name</i> . In the case of a simple NFS mount, <i>location</i> takes the form: <i>host</i> : <i>path</i> where <i>host</i> is the name of the host from which to mount the file system, and <i>path</i> is the path name of the directory to mount.

fncreate_fs(1M)

	<p>The <i>options</i> field is a comma-separated list of the mount options to use when mounting the location bound to <i>composite_name/name</i>. These options also apply to any subcontexts of <i>composite_name/name</i> that do not specify their own mount options. If <i>options</i> is given but <i>location</i> is not, the options apply to subcontexts only.</p> <p>If neither <i>options</i> nor a <i>location</i> is given, then no reference is bound to <i>composite_name/name</i>. Any existing reference is unbound.</p> <p>A single logical line may be continued across multiple input lines by escaping the newline with a '\ ' (backslash). Comments begin with a '#' that is either at the beginning of a line or is prefixed by whitespace, and end at the end of the line.</p>
Command-line Input	<p>If no <i>input_file</i> is specified on the command line, then the <i>options</i> and <i>location</i> fields given on the command line are bound directly to <i>composite_name</i>. This is equivalent to providing a one-line input file with a '.' in the <i>name</i> field.</p>
Multiple Locations	<p>Multiple <i>location</i> fields may be specified for NFS file systems that are exported from multiple, functionally-equivalent locations. If several locations in the list share the same path name, they may be combined using a comma-separated list of host names:</p> <pre>host1, host2, . . . : path</pre> <p>The hosts may be weighted, with the weighting factor appended to the host name as a non-negative integer in parentheses: the lower the number, the more desirable the server. The default weighting factor is 0 (most desirable). In the example:</p> <pre>alpha,bravo,charlie(1),delta(2):/usr/man</pre> <p>hosts alpha and bravo are the most desirable; host delta is the least desirable.</p> <p>See the USAGE section of automount(1M) for additional information on how the automounter interprets the location field.</p>
Variable Substitution	<p>Variable names, prefixed by '\$', may be used with the <i>options</i> or <i>location</i> fields. For example, a <i>location</i> may be given as:</p> <pre>svr1:/export/\$CPU</pre> <p>The automounter will substitute client-specific values for these variables when mounting the corresponding file systems. In the above example, \$CPU is replaced by the output of <code>uname -p</code>; for example, "sparc". See the USAGE section of automount(1M) for more information on how the automounter treats variable substitution.</p>
Alternate Input Format	<p>For additional compatibility with automount maps (see automount(1M)), the following input format is accepted:</p> <pre>name [options] [location . . .] \ /offset1 [options1] location1 . . . \ /offset2 [options2] location2 . . . \ . . .</pre>

where each *offset* field is a slash-separated hierarchy. This is interpreted as being equivalent to:

```
name      [options] [location . . . ^]
name/offset1  [options1] location1 . . .
name/offset2  [options2] location2 . . .
. . . (the first line being omitted if both options and location are omitted).
```

This format is for compatibility only; it provides no additional functionality. Its use is deprecated.

EXAMPLES **EXAMPLE 1** Using the `fncreate_fs` Command

The following examples illustrate the use of the `fncreate_fs` command. The call:

```
example% cat input1
src      -ro      svr1:/export/src
dist     -ro      svr2,svr3:/export/dist
example% fncreate_fs -f input1 org/engineering/fs
creates a file system context for the engineering organization. It specifies that
org/engineering/fs/src is a read-only NFS mount from server svr1, and that
org/engineering/fs/dist is a read-only NFS mount from either svr2 or svr3.
```

Once this is done, there are several equivalent ways to create the engineering organization's `src/cmd` context. It could be done using the composite name `org/engineering/fs`:

```
example% cat input2
src/cmd      svr1:/export/cmd
example% fncreate_fs -f input2 org/engineering/fs
```

Equivalently, it could be done using the composite name `org/engineering/fs/src`:

```
example% cat input3
cmd      svr1:/export/cmd
example% fncreate_fs -f input3 org/engineering/fs/src
```

The same results could also be achieved by:

```
example% fncreate_fs org/engineering/fs/src/cmd svr1:/export/cmd
```

Note that `cmd` will also be mounted read-only, since it is a subcontext of `src` and does not have mount options of its own.

In the first example of this section, the `-ro` mount option was specified for each entry in the input file. It could instead have been specified only once:

```
example% cat input4
.      -ro
src      svr1:/export/src
dist     svr2,svr3:/export/dist
example% fncreate_fs -f input4 org/engineering/fs
```

fncreate_fs(1M)

EXAMPLE 1 Using the fncreate_fs Command (Continued)

The `-ro` option here applies to all bindings in the context `org/engineering/fs` and any of its subcontexts. In particular, it also applies to the `cmd` context from the above examples.

The following will change the NFS server for the `src` context:

```
example% fncreate_fs org/engineering/fs/src svr4:/export/src
```

Had the `-r` option been used, the `cmd` subcontext would have been destroyed as well:

```
example% fncreate_fs -r org/engineering/fs/src svr4:/export/src
```

Only the FNS context is destroyed. The `/export/cmd` directory on `svr1` is not affected.

The file system contexts of users and hosts are not usually created by `fncreate_fs` (see the `NOTES` section below). The defaults set by `fncreate`, however, may be overridden. For example, the call:

```
example% fncreate_fs user/jane/fs svr1:/export/home/jane
sets Jane's file system to be an NFS mount from svr1.
```

EXIT STATUS 0 Operation was successful.

1 Operation failed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWfns

SEE ALSO `fnbind(1)`, `fnlist(1)`, `fnlookup(1)`, `fnunbind(1)`, `nis+(1)`, `automount(1M)`, `fncreate(1M)`, `fndestroy(1M)`, `attributes(5)`, `fns(5)`, `fns_files(5)`, `fns_nis(5)`, `fns_nis+(5)`, `fns_policies(5)`

NOTES The `fncreate_fs` command affects the FNS file system namespace only. It does not have any effect on the servers that export the files and directories from which the namespace is constructed. Destroying an FNS context does not remove any files on any server.

FNS policies specify that file system contexts are bound after the namespace identifier `fs` in composite names (see `fns_policies(5)`). Therefore, `composite_name` must contain an `fs`. The alias `_fs` may be used in place of `fs`.

The context named by the components of `composite_name` preceding `fs` must exist prior to the call to `fncreate_fs`, since `fncreate_fs` creates *only* file system contexts.

Default file system contexts for hosts and users are generally created by the command `fncreate(1M)`. These defaults may be overridden using `fncreate_fs`. Overriding a host's default file system context is unlikely to make sense.

The input file format is similar to the format of indirect automount maps (see `automount(1M)`). The differences are:

- the *name* field may be hierarchical, and may be `'.'`
- there are no included maps or special maps
- there may be entries with neither options nor locations
- the characters `'*'` and `'&'` have no special meaning

The process executing the `fncreate_fs` command may need certain credentials to update information in the underlying naming service. See `fns_nis(5)`, `fns_nis+(5)`, and `fns_files(5)` for more information.

fncreate_printer(1M)

NAME	fncreate_printer – create new printers in the FNS namespace
SYNOPSIS	fncreate_printer [-sv] <i>compositename printername printeraddr</i> [<i>printeraddr...</i>] fncreate_printer [-sv] [-f <i>filename</i>] <i>compositename</i>
DESCRIPTION	<p>fncreate_printer creates a new printer context for an <i>organization, user, host, or site</i> object. <i>compositename</i> is the FNS name of the object. fncreate_printer uses <i>printername</i> to name the new printer and binds it to an FNS reference constructed from the set of <i>printeraddrs</i>. fncreate_printer may also be used to add new <i>printeraddrs</i> for an existing <i>printername</i>.</p> <p>The command also supports creating a set of printers as listed in the file <i>filename</i>.</p> <p>The new printer context is created with the FNS name <i><compositename>/service/printer/<printername></i>. If the intermediate <i>service</i> or <i>printer</i> names do not exist, their FNS contexts are also created by this command. Normally, these intermediate contexts would be created by an administrative script that uses fncreate(1M), and is run at the time a new FNS organization is set up. The reference bound to the FNS printer name is of type <i>onc_printers</i> and is constructed from the set of <i>printeraddrs</i>. A <i>printeraddr</i> is of the form <i><addresstype> = <address></i>. See <i>printers.conf(4)</i> for the format of <i>printeraddr</i> and also the examples below for currently supported address types and address strings.</p> <p>An FNS printer name is accepted as a valid printer name by <i>lp(1)</i>, <i>lpstat(1)</i>, <i>cancel(1)</i>, <i>lpmove(1M)</i>, <i>lpr(1B)</i>, <i>lpq(1B)</i>, and <i>lprm(1B)</i>.</p> <p>The <i>printername</i> argument may be a slash-separated name. In this case, prior to creating the printer context denoted by the “leaf” name, this command will create printer context(s) for the intermediate node(s) if they do not already exist. See EXAMPLES.</p> <p>fncreate_printer creates entries in the naming service determined by fnselect(1M). See fnselect(1M) for more information on the default naming service and on selecting a naming service. Furthermore, the process executing the fncreate_printer command may require certain credentials to update information in the underlying namespace. See <i>fns_nis+(5)</i>, <i>fns_nis(5)</i>, and <i>fns_files(5)</i> for more information.</p>
OPTIONS	<p>-s The new <i>address</i> supersedes an existing address with the same <i>addresstype</i>, if any, for <i><compositename>/service/printer/<printername></i>. If this option is omitted, it appends the <i>printeraddr</i> to an existing reference, or creates a new reference using <i>printeraddr</i> for the printer.</p> <p>-v Displays information about individual printer contexts as they are created.</p> <p>-f <i>filename</i> Use <i>filename</i> to obtain a list of printers for which to create contexts. If this option is omitted, <i>/etc/printers.conf</i> is used as the</p>

fcreate_printer(1M)

		input file, in which case the <code>-s</code> option should be used to supersede the entries already present in this file.
OPERANDS	<i>filename</i>	The file that contains a list of printers to be created. This file uses the same format as <code>/etc/printers.conf</code> . See <code>printers.conf(4)</code> for more information.
	<i>printername</i>	The name of the new printer context created.
	<i>printeraddr</i>	An address to be associated with the printer context name.
	<i>compositename</i>	The FNS name for the <code>org</code> , <code>host</code> , <code>user</code> , or <code>site</code> object for which the new printer contexts are created.

EXAMPLES **EXAMPLE 1** Creating Printer Contexts

The following examples illustrate creating a set of printer contexts under an organization, a printer context for a user, and a printer context associated with a hierarchical printer name for a site, respectively. To create printers for an organization:

```
example% fcreate_printer -s org/marketing
```

This causes the creation of a printer context for every entry listed in the `/etc/printers.conf` file on the system where the command is executed. The printer contexts thus created are bound under the organization's printer context, `org/marketing/service/printer`. The `-s` flag is required to force the creation of the printer contexts in the underlying namespace, since the default `/etc/printers.conf` file is being used.

To create a printer named `ps` for user `jsmith` and associate it with the `killtree` printer served by the print server `paperwaster`:

```
example% fcreate_printer -s usr/jsmith ps bsdaddr=paperwaster,killtree
```

This causes `jsmith's ps` `printername` to be associated with the `killtree` printer on the server `paperwaster`, overwriting any existing address of type `bsdaddr`. The user can print to this printer using the command:

```
example% lp -d thisuser/service/printer/ps <filename>
```

To create a printer with the hierarchical name `color/fast` under a site:

```
example% fcreate_printer site/bldg14/northwing color/fast \  
bsdaddr=paperwaster,laser
```

This causes the printer named `site/bldg14/northwing/service/printer/color/fast` to be associated with the `laser` printer on server `paperwaster`. If the intermediate printer context `site/bldg14/northwing/service/printer/color` does not exist, it will also be created and associated with the same printer. If the printer name `site/bldg14/northwing/service/printer/color/fast` already exists and has an address of type `bsdaddr` associated with it, this command will fail.

EXIT STATUS	0	Successful operation.
--------------------	---	-----------------------

fncreate_printer(1M)

1 Operation failed.

Availability	SUNWfns				
SEE ALSO	<code>fnlist(1)</code> , <code>fnlookup(1)</code> , <code>fnunbind(1)</code> , <code>fncreate(1M)</code> , <code>attributes(5)</code> , <code>fns(5)</code> , <code>fns_policies(5)</code>				

fnselect(1M)

NAME	fnselect – select a specific naming service to use for the FNS Initial Context								
SYNOPSIS	fnselect [-D] fnselect <i>naming-service</i>								
DESCRIPTION	<i>fnselect</i> is used to set the specified naming service to be used to construct the bindings in the FNS Initial Context. This setting affects the entire machine and affects applications that make subsequent calls to <code>fn_ctx_handle_from_initial(3XFN)</code> . This setting can be changed only by an administrator who has root privilege on the machine.								
OPTIONS	-D Displays the actual naming service used to generate the FNS Initial Context.								
OPERANDS	<i>naming-service</i> The following are possible values for <i>naming-service</i> : <table><tr><td>default</td><td>Use the FNS default algorithm for determining the target naming service.</td></tr><tr><td>nisplus</td><td>Use NIS+ as the target naming service.</td></tr><tr><td>nis</td><td>Use NIS as the target naming service.</td></tr><tr><td>files</td><td>Use /etc files as the target naming service.</td></tr></table>	default	Use the FNS default algorithm for determining the target naming service.	nisplus	Use NIS+ as the target naming service.	nis	Use NIS as the target naming service.	files	Use /etc files as the target naming service.
default	Use the FNS default algorithm for determining the target naming service.								
nisplus	Use NIS+ as the target naming service.								
nis	Use NIS as the target naming service.								
files	Use /etc files as the target naming service.								
USAGE	When the <code>default</code> option is selected, FNS determines the underlying naming service using the following algorithm: <ul style="list-style-type: none">■ First, it checks for NIS+ with FNS installed.■ If the result is TRUE, then FNS assumes <code>nisplus</code> as the underlying naming service.■ Otherwise, it checks if the system is a NIS client.■ If TRUE, FNS assumes <code>nis</code> as the underlying naming service.■ Otherwise, FNS assumes <code>/etc files</code>. <p><i>fnselect</i> without any arguments displays the service currently selected for the Initial Context (one of <code>default</code>, <code>nisplus</code>, <code>nis</code>, or <code>files</code>).</p> <p>When the <code>-D</code> option is specified and the current setting is <code>default</code>, <i>fnselect</i> will use the algorithm that is used by FNS and display the actual naming service used for the FNS Initial Context.</p>								
EXAMPLES	EXAMPLE 1 Using The <i>fnselect</i> Command The command <pre>example% fnselect nisplus</pre> will select NIS+ as the underlying naming service for the FNS Initial Context. The command								

EXAMPLE 1 Using The fselect Command *(Continued)*

example% fselect
will print the naming service currently being used to generate the FNS Initial Context.

EXIT STATUS 0 Operation was successful.

1 Operation failed.

fnsypd(1M)

NAME	fnsypd – update FNS context on an NIS master server				
SYNOPSIS	<code>/usr/sbin/fnsypd</code>				
DESCRIPTION	<p>The <code>fnsypd</code> daemon is a Remote Procedure Call (RPC) service that accepts requests from NIS clients to update and modify Federated Naming Service (FNS) contexts. This daemon runs on an NIS master server with FNS on top of it. The <code>fnsypd</code> daemon requires the Secure Key Infrastructure (SKI) mechanism for authentication. The SKI mechanism is part of the SUNWski package. If SUNWski is not installed, authentication cannot be performed and users will receive "permission denied" error messages. The SUNWski man pages are located at <code>/opt/SUNWski/man</code>.</p> <p><code>fnsypd</code> enables users and hosts to modify only their respective FNS contexts. Organization, site, hostname and username contexts cannot be modified using <code>fnsypd</code>.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <table><tr><td>0</td><td>Successful completion.</td></tr><tr><td>1</td><td>An error occurred.</td></tr></table>	0	Successful completion.	1	An error occurred.
0	Successful completion.

NAME	format – disk partitioning and maintenance utility
SYNOPSIS	format [-f <i>command-file</i>] [-l <i>log-file</i>] [-x <i>data-file</i>] [-d <i>disk-name</i>] [-t <i>disk-type</i>] [-p <i>partition-name</i>] [-s] [-m] [-M] [-e] [<i>disk-list</i>]
DESCRIPTION	<p>format enables you to format, label, repair and analyze disks on your system. Unlike previous disk maintenance programs, format runs under SunOS. Because there are limitations to what can be done to the system disk while the system is running, format is also supported within the memory-resident system environment. For most applications, however, running format under SunOS is the more convenient approach.</p> <p>format first uses the disk list defined in <i>data-file</i> if the -x option is used. format then checks for the FORMAT_PATH environment variable, a colon-separated list of filenames and/or directories. In the case of a directory, format searches for a file named format.dat in that directory; a filename should be an absolute pathname, and is used without change. format adds all disk and partition definitions in each specified file to the working set. Multiple identical definitions are silently ignored. If FORMAT_PATH is not set, the path defaults to /etc/format.dat.</p> <p><i>disk-list</i> is a list of disks in the form c?t?d? or /dev/rdisk/c?t?d?s?. With the latter form, shell wildcard specifications are supported. For example, specifying /dev/rdisk/c2* causes format to work on all drives connected to controller c2 only. If no <i>disk-list</i> is specified, format lists all the disks present in the system that can be administered by format.</p> <p>Removable media devices are listed only when users execute format in expert mode (option -e). This feature is provided for backward compatibility. Use rmformat(1) for rewritable removable media devices.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -d <i>disk-name</i> Specify which disk should be made current upon entry into the program. The disk is specified by its logical name (for instance, -d c0t1d0). This can also be accomplished by specifying a single disk in the disk list. -e Enable SCSI expert menu. Note this option is not recommended for casual use. -f <i>command-file</i> Take command input from <i>command-file</i> rather than the standard input. The file must contain commands that appear just as they would if they had been entered from the keyboard. With this option, format does not issue continue? prompts; there is no need to specify y(es) or n(o) answers in the <i>command-file</i>. In non-interactive mode, format does not initially expect the input of a disk selection number. The user must specify the current working disk with the -d <i>disk-name</i>

format(1M)

	option when <code>format</code> is invoked, or specify <code>disk</code> and the disk selection number in the <i>command-file</i> .
<code>-l log-file</code>	Log a transcript of the <code>format</code> session to the indicated <i>log-file</i> , including the standard input, the standard output and the standard error.
<code>-m</code>	Enable extended messages. Provides more detailed information in the event of an error.
<code>-M</code>	Enable extended and diagnostic messages. Provides extensive information on the state of a SCSI device's mode pages, during formatting.
<code>-p partition-name</code>	Specify the partition table for the disk which is current upon entry into the program. The table is specified by its name as defined in the data file. This option can be used only if a disk is being made current, and its type is either specified or available from the disk label.
<code>-s</code>	Silent. Suppress all of the standard output. Error messages are still displayed. This is generally used in conjunction with the <code>-f</code> option.
<code>-t disk-type</code>	Specify the type of disk which is current upon entry into the program. A disk's type is specified by name in the data file. This option can only be used if a disk is being made current as described above.
<code>-x data-file</code>	Use the list of disks contained in <i>data-file</i> .

USAGE

When you invoke `format` with no options or with the `-e`, `-l`, `-m`, `-M`, or `-s` options, the program displays a numbered list of available disks and prompts you to specify a disk by list number. If the machine has more than 10 disks, press Space to see the next screenful of disks.

You can specify a disk by list number even if the disk is not displayed in the current screenful. For example, if the current screen shows disks 11-20, you can enter 25 to specify the twenty-fifth disk on the list. If you enter a number for a disk that is not currently displayed, `format` prompts you to verify your selection. If you enter a number from the displayed list, `format` silently accepts your selection.

After you specify a disk, `format` displays its main menu. This menu enables you to perform the following tasks:

analyze	Run read, write, and compare tests.
backup	Search for backup labels.
cache	Enable, disable, and query the state of the write cache and read cache. This menu item only appears when <code>format</code> is invoked with the <code>-e</code> option, and is only supported on SCSI devices..

	current	Display the device name, the disk geometry, and the pathname to the disk device.
	defect	Retrieve and print defect lists. This option is supported only on SCSI devices. IDE disks perform automatic defect management. Upon using the <code>defect</code> option on an IDE disk, you receive the message: <code>Controller does not support defect management or disk supports automatic defect management.</code>
	disk	Choose the disk that will be used in subsequent operations (known as the current disk.)
	fdisk	Run the <code>fdisk(1M)</code> program to create a <code>fdisk</code> partition for Solaris software (IA based systems only).
	format	Format and verify the current disk. This option is supported only on SCSI devices. IDE disks are pre-formatted by the manufacturer. Upon using the <code>format</code> option on an IDE disk, you receive the message: <code>Cannot format this drive. Please use your manufacturer-supplied formatting utility.</code>
	inquiry	Display the vendor, product name, and revision level of the current drive.
	label	Write a new label to the current disk.
	partition	Create and modify slices.
	quit	Exit the format menu.
	repair	Repair a specific block on the disk.
	save	Save new disk and slice information.
	type	Select (define) a disk type.
	verify	Read and display labels. Print information such as the number of cylinders, alternate cylinders, heads, sectors, and the partition table.
	volname	Label the disk with a new eight character volume name.
ENVIRONMENT VARIABLES	FORMAT_PATH	a colon-separated list of filenames and/or directories of disk and partition definitions. If a directory is specified, <code>format</code> searches for the file <code>format.dat</code> in that directory.
FILES	<code>/etc/format.dat</code>	default data file
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

WARNINGS When the `format` function is selected to format the Maxtor 207MB disk, the following message displays:

```
Mode sense page(4) reports rpm value as 0, adjusting it to 3600
```

This is a drive bug that may also occur with older third party drives. The above message is not an error; the drive will still function correctly.

Cylinder 0 contains the partition table (disk label), which can be overwritten if used in a raw disk partition by third party software.

NOTES `format` provides a help facility you can use whenever `format` is expecting input. You can request help about what information is expected by simply entering a question mark (?) and `format` prints a brief description of what type of input is needed. If you enter a ? at the menu prompt, a list of available commands is displayed.

For SCSI disks, formatting is done with both Primary and Grown defects list by default. However, if only Primary list is extracted in defect menu before formatting, formatting will be done with Primary list only.

Changing the state of the caches is only supported on SCSI devices, and not all SCSI devices support changing or saving the state of the caches.

NAME	fsck – check and repair file systems								
SYNOPSIS	<pre>fsck [-F FSType] [-m] [-V] [special...] fsck [-F FSType] [-n N y Y] [-V] [-o FSType-specific-options] [special...]</pre>								
DESCRIPTION	<p>fsck audits and interactively repairs inconsistent file system conditions. If the file system is inconsistent the default action for each correction is to wait for the user to respond <i>yes</i> or <i>no</i>. If the user does not have write permission fsck defaults to a <i>no</i> action. Some corrective actions will result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.</p> <p><i>FSType-specific-options</i> are options specified in a comma-separated (with no intervening spaces) list of options or keyword-attribute pairs for interpretation by the <i>FSType</i>-specific module of the command.</p> <p><i>special</i> represents the character special device on which the file system resides, for example, <code>/dev/rdisk/c1t0d0s7</code>. Note: the character special device, not the block special device, should be used. fsck will not work on a block device if it is mounted.</p> <p>If no <i>special</i> device is specified fsck checks the file systems listed in <code>/etc/vfstab</code>. Those entries in <code>/etc/vfstab</code> which have a character special device entry in the <code>fsckdev</code> field and have a non-zero numeric entry in the <code>fsckpass</code> field will be checked. Specifying <code>-F FSType</code> limits the file systems to be checked to those of the type indicated.</p> <p>If <i>special</i> is specified, but <code>-F</code> is not, the file system type will be determined by looking for a matching entry in <code>/etc/vfstab</code>. If no entry is found, the default local file system type specified in <code>/etc/default/fs</code> will be used.</p> <p>If a file system type supports parallel checking, for example, <code>ufs</code>, some file systems eligible for checking may be checked in parallel. Consult the file system-specific man page (for example, <code>fsck_ufs(1M)</code>) for more information.</p>								
OPTIONS	<p>The following generic options are supported:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>-F FSType</code></td> <td>Specify the file system type on which to operate.</td> </tr> <tr> <td style="vertical-align: top;"><code>-m</code></td> <td>Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:</td> </tr> <tr> <td></td> <td style="padding-left: 2em;">ufs fsck: sanity check: /dev/rdisk/c0t3d0s1 okay</td> </tr> <tr> <td style="vertical-align: top;"><code>-n -N</code></td> <td>Assume a <i>no</i> response to all questions asked by fsck; do not open the file system for writing.</td> </tr> </table>	<code>-F FSType</code>	Specify the file system type on which to operate.	<code>-m</code>	Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:		ufs fsck: sanity check: /dev/rdisk/c0t3d0s1 okay	<code>-n -N</code>	Assume a <i>no</i> response to all questions asked by fsck; do not open the file system for writing.
<code>-F FSType</code>	Specify the file system type on which to operate.								
<code>-m</code>	Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:								
	ufs fsck: sanity check: /dev/rdisk/c0t3d0s1 okay								
<code>-n -N</code>	Assume a <i>no</i> response to all questions asked by fsck; do not open the file system for writing.								

fsck(1M)

-v	Echo the expanded command line but do not execute the command. This option may be used to verify and to validate the command line.
-y Y	Assume a <i>yes</i> response to all questions asked by <i>fsck</i> .
-o <i>specific-options</i>	These <i>specific-options</i> can be any combination of the following separated by commas (with no intervening spaces).
b= <i>n</i>	Use block <i>n</i> as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running <i>newfs(1M)</i> with the <i>-Nv</i> options specified.
c	If the file system is in the old (static table) format, convert it to the new (dynamic table) format. If the file system is in the new format, convert it to the old format provided the old format can support the file system configuration. In interactive mode, <i>fsck</i> will list the direction the conversion is to be made and ask whether the conversion should be done. If a negative answer is given, no further operations are done on the file system. In preen mode, the direction of the conversion is listed and done if possible without user interaction. Conversion in preen mode is best used when all the file systems are being converted at once. The format of a file system can be determined from the first line of output from <i>fstyp(1M)</i> . Note: the <i>c</i> option is seldom used and is included only for compatibility with pre-4.1 releases. There is no guarantee that this option will be included in future releases.
f	Force checking of file systems regardless of the state of their super block clean flag.
p	Check and fix the file system non-interactively (“preen”). Exit immediately if there is a problem requiring intervention. This option is required to enable parallel file system checking.
w	Check writable file systems only.
EXIT STATUS	0 file system is okay and does not need checking

- 1 erroneous parameters are specified
- 32 file system is unmounted and needs checking (`fscck -m` only)
- 33 file system is already mounted
- 34 cannot stat device
- 36 uncorrectable errors detected - terminate normally
- 37 a signal was caught during processing
- 39 uncorrectable errors detected - terminate immediately
- 40 for root, same as 0.

USAGE See `largefile(5)` for the description of the behavior of `fscck` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES `/etc/default/fs` default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`.

`LOCAL` The default partition for a command if no `FSType` is specified.

`/etc/vfstab` list of default parameters for each file system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `clri(1M)`, `fscck_cacheufs(1M)`, `fscck_ufs(1M)`, `fsdb_ufs(1M)`, `fsirand(1M)`, `fstyp(1M)`, `mkfs(1M)`, `mkfs_ufs(1M)`, `mountall(1M)`, `newfs(1M)`, `reboot(1M)`, `fs_ufs(4)`, `vfstab(4)`, `attributes(5)`, `largefile(5)`

WARNINGS The operating system buffers file system data. Running `fscck` on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be *unmounted* when `fscck` is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after `fscck` is run. Quite often, however, this will not be sufficient. A panic will probably occur if running `fscck` on a file system modifies the file system.

NOTES This command may not be supported for all *FSTypes*.

Running `fscck` on file systems larger than 2 Gb fails if the user chooses to use the block interface to the device:

fsck(1M)

```
fsck /dev/dsk/c?t?d?s?
```

rather than the raw (character special) device:

```
fsck /dev/rdisk/c?t?d?s?
```

Starting with Solaris 9, `fsck` manages extended attribute data on the disk. (See `fsattr(5)` for a description of extended file attributes.) A file system with extended attributes can be mounted on versions of Solaris that are not attribute-aware (versions prior to Solaris 9), but the attributes will not be accessible and `fsck` will strip them from the files and place them in `lost+found`. Once the attributes have been stripped, the file system is completely stable on versions of Solaris that are attribute-aware, but would be considered corrupted on attribute-aware versions. In the latter circumstance, run the attribute-aware `fsck` to stabilize the file system before using it in an attribute-aware environment.

NAME fsock_cachefs – check integrity of data cached with CacheFS

SYNOPSIS **fsock** -F cachefs [-m | -o | noclean] *cache_directory*

DESCRIPTION The CacheFS version of the `fsock` command checks the integrity of a cache directory. By default it corrects any CacheFS problems it finds. There is no interactive mode. The most likely invocation of `fsock` for CacheFS file systems is at boot time from an entry in the `/etc/vfstab` file (see `vfstab(4)`).

OPTIONS Two command line options are available:

-m Check, but do not repair.

-o noclean Force a check on the cache even if there is no reason to suspect there is a problem.

EXAMPLES **EXAMPLE 1** An example of the `fsock` command.

The following example forces a check on the cache directory `/cache3`:

```
example% fsock -F cachefs -o noclean /cache3
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `cfsadmin(1M)`, `fsock(1M)`, `mount_cachefs(1M)`, `vfstab(4)`, `attributes(5)`

fsck_pcfs(1M)

NAME	fsck_pcfs – file system consistency check and interactive repair				
SYNOPSIS	fsck -F pcfs [<i>generic_options</i>] <i>special</i> fsck -F pcfs [<i>generic_options</i>] [-o <i>specific_options</i>] <i>special</i>				
DESCRIPTION	<p>The <code>fsck</code> utility audits and interactively repairs inconsistent conditions on file systems. <i>special</i> represents the character special device on which the file system resides, for example <code>/dev/rdiskette</code>. The character special device, not the block special device, should be used.</p> <p>In the case of correcting serious inconsistencies, by default, <code>fsck</code> asks for confirmation before making a repair and waits for the operator to respond either <code>yes</code> or <code>no</code>. If the operator does not have write permission on the file system, <code>fsck</code> defaults to a <code>-n</code> (no corrections) action. See <code>fsck(1M)</code>.</p> <p>Repairing some file system inconsistencies may result in loss of data. The amount and severity of data loss may be determined from the diagnostic output.</p> <p>When executed with the verify option (<code>-o v</code>), <code>fsck_pcfs</code> automatically scans the entire file system to verify that all of its allocation units are accessible. If it finds any units inaccessible, it updates the file allocation table (FAT) appropriately. It also updates any effected directory entries to reflect the problem. This directory update includes truncating the file at the point in its allocation chain where the file data is no longer accessible. Any remaining accessible allocation units become orphaned.</p> <p>Orphaned chains of accessible allocation units are, with the operator's concurrence, linked back into the file system as files in the root directory. These files are assigned names of the form <code>fileNNNN.chk</code>, where the <i>Ns</i> are digits in the integral range from 0 through 9.</p> <p>After successfully scanning and correcting any errors in the file system, <code>fsck</code> displays a summary of information about the file system. This summary includes the size of the file system in bytes, the number of bytes used in directories and individual files, and the number of available allocation units remaining in the file system.</p>				
OPTIONS	<p><i>generic_options</i></p> <p>The following generic options are supported:</p> <table><tr><td><code>-m</code></td><td>Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, <code>fsck</code> displays a message such as: <code>pcfs fsck: sanity check: /dev/rdiskette okay</code></td></tr><tr><td><code>-n -N</code></td><td>Assume a no response to all questions asked by <code>fsck</code>; do not open the file system for writing.</td></tr></table>	<code>-m</code>	Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, <code>fsck</code> displays a message such as: <code>pcfs fsck: sanity check: /dev/rdiskette okay</code>	<code>-n -N</code>	Assume a no response to all questions asked by <code>fsck</code> ; do not open the file system for writing.
<code>-m</code>	Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, <code>fsck</code> displays a message such as: <code>pcfs fsck: sanity check: /dev/rdiskette okay</code>				
<code>-n -N</code>	Assume a no response to all questions asked by <code>fsck</code> ; do not open the file system for writing.				

fsck_pcfs(1M)

- v Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line.
- y | -Y Assume a yes response to all questions asked by fsck.
- o *specific_options* Specify pcfs file system specific options in a comma-separated list, in any combination, with no intervening spaces.
 - v Verify all allocation units are accessible prior to correcting inconsistencies in the metadata.
 - p Check and fix the file system non-interactively (p_reen). Exit immediately if there is a problem requiring intervention.
 - w Check writable file systems only.

FILES *special* The device which contains the pcfs. The device name for a diskette is specified as /dev/rdiskette0 for the first diskette drive, or /dev/rdiskette1 for a second diskette drive. A hard disk device or high-capacity removable device name must be qualified with a suffix to indicate the proper FDISK partition.

For example, in the names: /dev/rdisk/c0t0d0p0:c and /dev/rdisk/c0t4d0s2:c, the :c suffix indicates the first partition on the disk contains the pcfs.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Stable

SEE ALSO fsck(1M), fstyp(1M), fdisk(1M), mkfs(1M), mkfs_pcfs(1M), mountall(1M), attributes(5), pcfs(7FS),

WARNINGS The operating system buffers file system data. Running fsck on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be unmounted when fsck is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after fsck is run. Quite often, however, this is not sufficient. A panic will probably occur if running fsck on a file system modifies the file system.

fsck_udfs(1M)

NAME	<code>fsck_udfs</code> – file system consistency check and interactive repair
SYNOPSIS	<code>fsck -F udfs [generic_options] [special ...]</code> <code>fsck -F udfs [generic_options] [-o specific_options] [special ...]</code>
DESCRIPTION	<p><code>fsck</code> audits and interactively repairs inconsistent conditions on file systems. A file system to be checked can be specified by giving the name of the block or character special device or by giving the name of its mount point if a matching entry exists in <code>/etc/vfstab</code>.</p> <p><i>special</i> represents the character special device, for example, <code>/dev/rdisk/c0t2d0s0</code>, on which the file system resides. The character special device, not the block special device should be used. <code>fsck</code> does not work on a mounted block device.</p> <p>If no special device is specified, all <code>udfs</code> file systems specified in the <code>vfstab</code> file with a <code>fsckdev</code> entry are checked. If the <code>-p</code> (<code>green</code>) option is specified, <code>udfs</code> file systems with an <code>fsckpass</code> number greater than 1 are checked in parallel. See <code>fsck(1M)</code>.</p> <p>In the case of correcting serious inconsistencies, by default, <code>fsck</code> asks for confirmation before making a repair and waits for the operator to respond with either <code>yes</code> or <code>no</code>. If the operator does not have write permission on the file system, <code>fsck</code> defaults to the <code>-n</code> (no corrections) option. See <code>fsck(1M)</code>.</p> <p>Repairing some file system inconsistencies can result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.</p> <p><code>fsck</code> automatically corrects innocuous inconsistencies. It displays a message for each corrected inconsistency that identifies the nature of the correction which took place on the file system. After successfully correcting a file system, <code>fsck</code> prints the number of files on that file system and the number of used and free blocks.</p> <p>Inconsistencies checked are as follows:</p> <ul style="list-style-type: none">■ Blocks claimed by more than one file or the free list■ Blocks claimed by a file or the free list outside the range of the file system■ Incorrect link counts in file entries■ Incorrect directory sizes■ Bad file entry format■ Blocks not accounted for anywhere■ Directory checks, file pointing to unallocated file entry and absence of a parent directory entry■ Descriptor checks, more blocks for files than there are in the file system■ Bad free block list format■ Total free block count incorrect <p>OPTIONS The following options are supported:</p>

generic_options

The following *generic_options* are supported:

-m

Check but do not repair. This option checks to be sure that the file system is suitable for mounting, and returns the appropriate exit status. If the file system is ready for mounting, `fsck` displays a message such as:

```
udfs fsck: sanity check: /dev/rdisk/c0t2d0s0 okay
```

-n | -N

Assume a no response to all questions asked by `fsck`; do not open the file system for writing.

-V

Echo the expanded command line, but do not execute the command. This option can be used to verify and to validate the command line.

-y | -Y

Assume a yes response to all questions asked by `fsck`.

-o *specific_options*

Specify `udfs` file system specific options in a comma-separated list with no intervening spaces. The following *specific_options* are available:

f

Force checking of file systems regardless of the state of their logical volume integrity state.

p

Check and fix the file system non-interactively (`preen`). Exit immediately if there is a problem that requires intervention. This option is required to enable parallel file system checking.

w

Check writable file systems only.

FILES /etc/vfstab List of default parameters for each file system.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWudf

SEE ALSO `fsck(1M)`, `fsdb_udfs(1M)`, `fstyp(1M)`, `mkfs(1M)`, `mkfs_udfs(1M)`, `mountall(1M)`, `reboot(1M)`, `vfstab(4)`, `attributes(5)`

WARNINGS The operating system buffers file system data. Running `fsck` on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, use `fsck` only when the file system is unmounted. If this is

fsck_udfs(1M)

not possible, take care that the system is quiescent and that it is rebooted immediately after running `fsck`. A panic will probably occur if running `fsck` on a file system that modifies the file system while it is mounted.

If an unmount of the file system is not done before the system is shut down, the file system might become corrupted. In this case, a file system check needs to be completed before the next mount operation.

DIAGNOSTICS

not writeable

You cannot write to the device.

Currently Mounted on

The device is already mounted and cannot run `fsck`.

FILE SYSTEM WAS MODIFIED

File system has been modified to bring it to a consistent state.

Can't read allocation extent

Cannot read the block containing allocation extent.

Bad tag on alloc extent

Invalid tag detected when expecting an allocation extent.

Volume sequence tag error

Invalid tag detected in the volume sequence.

Space bitmap tag error

Invalid tag detected in the space bitmap.

UNEXPECTED INCONSISTENCY; RUN `fsck` MANUALLY

Use `fsck` in interactive mode.

NAME	fsck_ufs – file system consistency check and interactive repair
SYNOPSIS	<pre>fsck -F ufs [<i>generic-options</i>] [<i>special...</i>]</pre> <pre>fsck -F ufs [<i>generic-options</i>] [-o <i>specific-options</i>] [<i>special...</i>]</pre>
DESCRIPTION	<p>The <code>fsck</code> utility audits and interactively repairs inconsistent conditions on file systems. A file system to be checked may be specified by giving the name of the block or character <i>special</i> device or by giving the name of its mount point if a matching entry exists in <code>/etc/vfstab</code>.</p> <p>The <i>special</i> parameter represents the character special device, for example, <code>/dev/rdisk/c1t0d0s7</code>, on which the file system resides. The character special device, not the block special device should be used. The <code>fsck</code> utility will not work on a block device if the block device is mounted, unless the file system is error-locked.</p> <p>If no <i>special</i> device is specified, all <code>ufs</code> file systems specified in the <code>vfstab</code> with a <code>fsckdev</code> entry will be checked. If the <code>-p</code> (“preen”) option is specified, <code>ufs</code> file systems with an <code>fsckpass</code> number greater than 1 are checked in parallel. See <code>fsck(1M)</code>.</p> <p>In the case of correcting serious inconsistencies, by default, <code>fsck</code> asks for confirmation before making a repair and waits for the operator to respond either <code>yes</code> or <code>no</code>. If the operator does not have write permission on the file system, <code>fsck</code> will default to a <code>-n</code> (no corrections) action. See <code>fsck(1M)</code>.</p> <p>Repairing some file system inconsistencies can result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.</p> <p>The <code>fsck</code> utility automatically corrects innocuous inconsistencies such as unreferenced inodes, too-large link counts in inodes, missing blocks in the free list, blocks appearing in the free list and also in files, or incorrect counts in the super block. It displays a message for each inconsistency corrected that identifies the nature of the correction on the file system which took place. After successfully correcting a file system, <code>fsck</code> prints the number of files on that file system, the number of used and free blocks, and the percentage of fragmentation.</p> <p>Inconsistencies checked are as follows:</p> <ul style="list-style-type: none"> ■ Blocks claimed by more than one inode or the free list. ■ Blocks claimed by an inode or the free list outside the range of the file system. ■ Incorrect link counts. ■ Incorrect directory sizes. ■ Bad inode format. ■ Blocks not accounted for anywhere. ■ Directory checks, file pointing to unallocated inode, inode number out of range, and absence of <code>‘.’</code> and <code>‘. .’</code> as the first two entries in each directory.

fsck_ufs(1M)

- Super Block checks: more blocks for inodes than there are in the file system.
- Bad free block list format.
- Total free block and/or free inode count incorrect.

Orphaned files and directories (allocated but unreferenced) are, with the operator's concurrence, reconnected by placing them in the `lost+found` directory. The name assigned is the inode number. If the `lost+found` directory does not exist, it is created. If there is insufficient space in the `lost+found` directory, its size is increased.

An attempt to mount a `ufs` file system with the `-o nolargefiles` option will fail if the file system has ever contained a large file (a file whose size is greater than or equal to 2 Gbyte). Invoking `fsck` resets the file system state if no large files are present in the file system. A successful mount of the file system after invoking `fsck` indicates the absence of large files in the file system. An unsuccessful mount attempt indicates the presence of at least one large file. See `mount_ufs(1M)`.

OPTIONS

The *generic-options* consist of the following options:

- `-m` Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, `fsck` displays a message such as:
- ```
ufs fsck: sanity check:
/dev/rdisk/c0t3d0s1 okay
```
- `-n | N` Assume a no response to all questions asked by `fsck`; do not open the file system for writing.
- `-v` Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line.
- `-y | Y` Assume a yes response to all questions asked by `fsck`.

See generic `fsck(1M)` for the details for specifying *special*.

- `-o specific-options` Specify `ufs` file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces).
- `b=n`  
Use block *n* as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running `newfs(1M)` with the `-Nv` options specified.
- `c`  
If the file system is in the old (static table) format, convert it to the new (dynamic table) format. If the file system is in the new format, convert it to the old

format provided the old format can support the file system configuration. In interactive mode, `fscck` will list the direction the conversion is to be made and ask whether the conversion should be done. If a negative answer is given, no further operations are done on the file system. In preen mode, the direction of the conversion is listed and done if possible without user interaction. Conversion in preen mode is best used when all the file systems are being converted at once. The format of a file system can be determined from the first line of output from `fstyp(1M)`. Note: the `c` option is seldom used and is included only for compatibility with pre-4.1 releases. There is no guarantee that this option will be included in future releases.

**f**  
Force checking of file systems regardless of the state of their super block clean flag.

**P**  
Check and fix the file system non-interactively (“preen”). Exit immediately if there is a problem requiring intervention. This option is required to enable parallel file system checking.

**w**  
Check writable file systems only.

**FILES** /etc/vfstab list of default parameters for each file system

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `clri(1M)`, `fscck(1M)`, `fsdb_ufs(1M)`, `fsirand(1M)`, `fstyp(1M)`, `mkfs(1M)`, `mkfs_ufs(1M)`, `mount_ufs(1M)`, `mountall(1M)`, `newfs(1M)`, `reboot(1M)`, `fs_ufs(4)`, `vfstab(4)`, `attributes(5)`, `largefile(5)`

**WARNINGS** The operating system buffers file system data. Running `fscck` on a mounted file system can cause the operating system’s buffers to become out of date with respect to the disk. For this reason, the file system should be *unmounted* when `fscck` is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after `fscck` is run. Quite often, however, this will not be sufficient. A panic will probably occur if running `fscck` on a file system modifies the file system.

fsck\_ufs(1M)

**NOTES** | It is usually faster to check the character special device than the block special device.

Running `fsck` on file systems larger than 2 Gb fails if the user chooses to use the block interface to the device:

```
fsck /dev/dsk/c?t?d?s?
```

rather than the raw (character special) device:

```
fsck /dev/rdsk/c?t?d?s?
```

| <b>NAME</b>        | fsdb – file system debugger                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>fsdb</b> [-F <i>FSType</i> ] [-V] [-o <i>FSType-specific_options</i> ] <i>special</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>DESCRIPTION</b> | fsdb is a file system debugger that allows for the manual repair of a file system after a crash. <i>special</i> is a special device used to indicate the file system to be debugged. fsdb is intended for experienced users only. <i>FSType</i> is the file system type to be debugged. Since different <i>FSTypes</i> have different structures and hence different debugging capabilities, the manual pages for the <i>FSType</i> -specific fsdb should be consulted for a more detailed description of the debugging capabilities.                                                                                          |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-F Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <code>/etc/vfstab</code> by matching the <i>special</i> with an entry in the table, or by consulting <code>/etc/default/fs</code>.</p> <p>-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from <code>/etc/vfstab</code>. This option may be used to verify and validate the command line.</p> <p>-o Specify <i>FSType</i>-specific options.</p> |                |                 |              |         |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of fsdb when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>FILES</b>       | <p><code>/etc/default/fs</code> default local file system type. Default values can be set for the following flags in <code>/etc/default/fs</code>. For example: LOCAL=ufs</p> <p>LOCAL: The default partition for a command if no <i>FSType</i> is specified.</p> <p><code>/etc/vfstab</code> list of default parameters for each file system</p>                                                                                                                                                                                                                                                                              |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |

| <b>NAME</b>        | fsdb_udfs – udfs file system debugger                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>fsdb</b> [-F] udfs [ <i>generic_option</i> ] [-o <i>specific_option</i> ] <i>special</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>fsdb_udfs</code> command is an interactive tool that can be used to patch up a damaged udfs file system. <code>fsdb_udfs</code> has conversions to translate block and i-numbers into their corresponding disk addresses. Mnemonic offsets to access different parts of an inode are also included. Mnemonic offsets greatly simplify the process of correcting control block entries or descending the file system tree.</p> <p><code>fsdb</code> contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking <code>fsdb</code> with the <code>-o</code> option or by using the <code>o</code> command.</p> <p><code>fsdb</code> reads one block at a time, and therefore works with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. In order to modify any portion of the disk, <code>fsdb</code> must be invoked with the <code>-w</code> option.</p> <p>Wherever possible, <code>adb</code>-like syntax has been adopted to promote the use of <code>fsdb</code> through familiarity.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-o <i>specific_option</i></code> Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following specific options are supported:<ul style="list-style-type: none"><li><code>o</code> Override some error conditions.</li><li><code>p=<i>string</i></code> Set prompt to <i>string</i>.</li><li><code>w</code> Open for write.</li><li><code>?</code> Display usage.</li></ul></li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>USAGE</b>       | <p>Numbers are considered hexadecimal by default. The user has control over how data is to be displayed or accepted. The <code>base</code> command displays or sets the input and output base. Once set, all input defaults to this base and all output displays in this base. The base can be overridden temporarily for input by preceding hexadecimal numbers by <code>0x</code>, preceding decimal numbers with a <code>0t</code>, or octal numbers with a <code>0</code>. Hexadecimal numbers beginning with <code>a-f</code> or <code>A-F</code> must be preceded with a <code>0x</code> to distinguish them from commands.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Disk addressing by `fsdb` is at the byte level. However, `fsdb` offers many commands to convert a desired inode, directory entry, block, and so forth, to a byte address. After the address has been calculated, `fsdb` records the result in the current address (`dot`).

Several global values are maintained by `fsdb`:

- Current base (referred to as `base`)
- Current address (referred to as `dot`)
- Current inode (referred to as `inode`)
- Current count (referred to as `count`)
- Current type (referred to as `type`)

Most commands use the preset value of `dot` in their execution. For example,

```
> 2:inode
```

first sets the value of `dot` (`.`) to 2, colon (`:`), signifies the start of a command, and the `inode` command sets `inode` to 2. A count is specified after a comma (`,`). Once set, count remains at this value until a new command is encountered that resets the value back to 1 (the default).

So, if

```
> 2000,400/X
```

is entered, 400 hex longs are listed from 2000, and when completed, the value of `dot` is  $2000 + 400 * \text{sizeof}(\text{long})$ . If a RETURN is then entered, the output routine uses the current values of `dot`, `count`, and `type` and displays 400 more hex longs. An asterisk (`*`) causes the entire block to be displayed. An example showing several commands and the use of RETURN would be:

```
> 2:ino; 0:dir?d
```

or

```
> 2:ino; 0:db:block?d
```

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, subsequently entering a RETURN, plus (`+`), or minus (`-`) advances to subsequent entries. Notice that

```
> 2:inode; :ls
```

or

```
> :ls /
```

is again synonymous.

## Expressions

The following symbols are recognized by `fsdb`:

|        |                                                                                                                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RETURN | Update the value of <code>dot</code> by the current value of <code>type</code> and <i>display</i> using the current value of <code>count</code> .                                                                                                                           |
| #      | Update the value of <code>dot</code> by specifying a numeric expression. Specify numeric expressions using addition, subtraction, multiplication, and division operators ( <code>+</code> , <code>-</code> , <code>*</code> , and <code>%</code> ). Numeric expressions are |

|                |                                                                                                                                                                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | evaluated from left to right and can use parentheses. After evaluation, the value of dot is updated.                                                                                                                                                                                                |
| , <i>count</i> | Update the count indicator. The global value of <i>count</i> is updated to <i>count</i> . The value of <i>count</i> remains until a new command is run. A <i>count</i> specifier of * attempts to show a blocks's worth of information. The default for <i>count</i> is 1.                          |
| ? <i>f</i>     | Display in structured style with format specifier <i>f</i> . See Formatted Output.                                                                                                                                                                                                                  |
| / <i>f</i>     | Display in unstructured style with format specifier <i>f</i> . See Formatted Output.                                                                                                                                                                                                                |
| .              | Display the value of dot.                                                                                                                                                                                                                                                                           |
| + <i>e</i>     | Increment the value of dot by the expression <i>e</i> . The amount actually incremented is dependent on the size of type: $\text{dot} = \text{dot} + e * \text{sizeof}(\text{type})$ The default for <i>e</i> is 1.                                                                                 |
| - <i>e</i>     | Decrement the value of dot by the expression <i>e</i> . See +.                                                                                                                                                                                                                                      |
| * <i>e</i>     | Multiply the value of dot by the expression <i>e</i> . Multiplication and division don't use <i>type</i> . In the above calculation of dot, consider the <code>sizeof</code> ( <i>type</i> ) to be 1.                                                                                               |
| % <i>e</i>     | Divide the value of dot by the expression <i>e</i> . See *.                                                                                                                                                                                                                                         |
| < <i>name</i>  | Restore an address saved in register <i>name</i> . <i>name</i> must be a single letter or digit.                                                                                                                                                                                                    |
| > <i>name</i>  | Save an address in register <i>name</i> . <i>name</i> must be a single letter or digit.                                                                                                                                                                                                             |
| = <i>f</i>     | Display indicator. If <i>f</i> is a legitimate format specifier (see Formatted Output), then the value of dot is displayed using format specifier <i>f</i> . Otherwise, assignment is assumed. See = [s] [e].                                                                                       |
| = [s] [e]      | Change the value of dot using an assignment indicator. The address pointed to by dot has its contents changed to the value of the expression <i>e</i> or to the ASCII representation of the quoted (") string <i>s</i> . This can be useful for changing directory names or ASCII file information. |
| += <i>e</i>    | Change the value of dot using an incremental assignment. The address pointed to by dot has its contents incremented by expression <i>e</i> .                                                                                                                                                        |
| -- <i>e</i>    | Change the value of dot using a decremental assignment. Decrement the contents of the address                                                                                                                                                                                                       |

pointed to by dot by expression *e*.

## Commands

A command must be prefixed by a colon (:). Only enough letters of the command to uniquely distinguish it are needed. Multiple commands can be entered on one line by separating them by a SPACE, TAB, or semicolon (;).

To view a potentially unmounted disk in a reasonable manner, `fsdb` supports the `cd`, `pwd`, `ls`, and `find` commands. The functionality of each of these commands basically matches that of its UNIX counterpart. See `cd(1)`, `pwd(1)`, `ls(1)`, and `find(1)` for details. The `*`, `,`, `?`, and `-` wildcard characters are also supported.

The following commands are supported:

|                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>base[=<i>b</i>]</code>                                     | Display or set the base. All input and output is governed by the current base. Without the <code>= <i>b</i></code> , displays the current base. Otherwise, sets the current base to <i>b</i> . Base is interpreted using the old value of base, so to ensure correctness use the <code>0</code> , <code>0t</code> , or <code>0x</code> prefix when changing the base. The default for base is hexadecimal. |
| <code>block</code>                                               | Convert the value of dot to a block address.                                                                                                                                                                                                                                                                                                                                                               |
| <code>cd [<i>dir</i>]</code>                                     | Change the current directory to directory <i>dir</i> . The current values of inode and dot are also updated. If <i>dir</i> is not specified, changes directories to inode 2, root (/).                                                                                                                                                                                                                     |
| <code>directory</code>                                           | If the current inode is a directory, converts the value of dot to a directory slot offset in that directory, and dot now points to this entry.                                                                                                                                                                                                                                                             |
| <code>file</code>                                                | Set the value of dot as a relative block count from the beginning of the file. The value of dot is updated to the first byte of this block.                                                                                                                                                                                                                                                                |
| <code>find <i>dir</i> [-name <i>n</i>]   [-inum <i>i</i>]</code> | Find files by name or i-number. Recursively searches directory <i>dir</i> and below for file names whose i-number matches <i>i</i> or whose name matches pattern <i>n</i> . Only one of the two options ( <code>-name</code> or <code>-inum</code> ) can be used at one time. The <code>-print</code> is not necessary or accepted.                                                                        |
| <code>fill=<i>p</i></code>                                       | Fill an area of disk with pattern <i>p</i> . The area of disk is delimited by dot and count.                                                                                                                                                                                                                                                                                                               |
| <code>inode</code>                                               | Convert the value of dot to an inode address. If successful, the current value of                                                                                                                                                                                                                                                                                                                          |

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                            | inode is updated as well as the value of dot. As a convenient shorthand, if <code>:inode</code> appears at the beginning of the line, the value of dot is set to the current inode and that inode is displayed in inode format.                                                                                                                                                                        |
| <code>ls [ -R ] [ -l ] pat1 pat2...</code> | List directories or files. If no file is specified, the current directory is assumed. Either or both of the options can be used (but, if used, must be specified before the filename specifiers). Wild card characters are available and multiple arguments are acceptable. The long listing shows only the i-number and the name; use the inode command with <code>?i</code> to get more information. |
| <code>override</code>                      | Toggle the value of override. Some error conditions might be overridden if override is toggled to on.                                                                                                                                                                                                                                                                                                  |
| <code>prompt "p"</code>                    | Change the <code>fsdb</code> prompt to <code>p</code> . <code>p</code> must be enclosed in quotes.                                                                                                                                                                                                                                                                                                     |
| <code>pwd</code>                           | Display the current working directory.                                                                                                                                                                                                                                                                                                                                                                 |
| <code>quit</code>                          | Quit <code>fsdb</code> .                                                                                                                                                                                                                                                                                                                                                                               |
| <code>tag</code>                           | Convert the value of dot and if this is a valid tag, print the volume structure according to the tag.                                                                                                                                                                                                                                                                                                  |
| <code>!</code>                             | Escape to the shell.                                                                                                                                                                                                                                                                                                                                                                                   |

**Inode Commands**

In addition to the above commands, several other commands deal with inode fields and operate directly on the current inode (they still require the colon (:)). They can be used to more easily display or change the particular fields. The value of dot is only used by the `:db` and `:ib` commands. Upon completion of the command, the value of dot is changed so that it points to that particular field. For example,

```
> :ln+=1
increments the link count of the current inode and sets the value of dot to the address of the link count field.
```

The following inode commands are supported:

|                  |               |
|------------------|---------------|
| <code>at</code>  | Access time   |
| <code>bs</code>  | Block size    |
| <code>ct</code>  | Creation time |
| <code>gid</code> | Group id      |
| <code>ln</code>  | Link number   |

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mt   | Modification time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| md   | Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| maj  | Major device number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| min  | Minor device number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| nm   | This command actually operates on the directory name field. Once poised at the desired directory entry (using the <code>directory</code> command), this command allows you to change or display the directory name. For example,<br><br><pre>&gt; 7:dir:nm="foo"</pre> gets the 7th directory entry of the current inode and changes its name to <code>foo</code> . Directory names cannot be made larger than the field allows. If an attempt is made to make a directory name larger than the field allows,, the string is truncated to fit and a warning message is displayed. |
| sz   | File size                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| uid  | User ID                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| uniq | Unique ID                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Formatted Output**

Formatted output comes in two styles and many format types. The two styles of formatted output are: structured and unstructured. Structured output is used to display inodes, directories, and so forth. Unstructured output displays raw data.

Format specifiers are preceded by the slash (/) or question mark (?) character. *type* is updated as necessary upon completion.

The following format specifiers are preceded by the ? character:

- i    Display as inodes in the current base.
- d    Display as directories in the current base.

The following format specifiers are preceded by the / character:

- b            Display as bytes in the current base.
- c            Display as characters.
- o | O        Display as octal shorts or longs.
- d | D        Display as decimal shorts or longs.
- x | X        Display as hexadecimal shorts or longs.

**EXAMPLES**

**EXAMPLE 1** Using `fsdb` as a calculator for complex arithmetic

The following command displays 2010 in decimal format, and is an example of using `fsdb` as a calculator for complex arithmetic.

```
> 2000+400%(20+20)=D
```

**EXAMPLE 2** Using fsdb to display an i-number in inode format

The following command displays the i-number 386 in inode format. 386 becomes the current inode.

```
> 386:ino?i
```

**EXAMPLE 3** Using fsdb to change the link count

The following command changes the link count for the current inode to 4.

```
> :ln=4
```

**EXAMPLE 4** Using fsdb to increment the link count

The following command increments the link count by 1.

```
> :ln+=1
```

**EXAMPLE 5** Using fsdb to display the creation time as a hexadecimal long

The following command displays the creation time as a hexadecimal long.

```
> :ct=X
```

**EXAMPLE 6** Using fsdb to display the modification time in time format

The following command displays the modification time in time format.

```
> :mt=t
```

**EXAMPLE 7** Using fsdb to display in ASCII

The following command displays, in ASCII, block 0 of the file associated with the current inode.

```
> 0:file/c
```

**EXAMPLE 8** Using fsdb to display the directory entries for the root inode

The following command displays the first block's directory entries for the root inode of this file system. This command stops prematurely if the EOF is reached.

```
> 2:ino,*?d
```

**EXAMPLE 9** Using fsdb to change the current inode

The following command changes the current inode to that associated with the 5th directory entry (numbered from 0) of the current inode. The first logical block of the file is then displayed in ASCII.

**EXAMPLE 9** Using fsdb to change the current inode (Continued)

```
> 5:dir:inode; 0:file,*/c
```

**EXAMPLE 10** Using fsdb to change the i-number

The following command changes the i-number for the 7th directory slot in the root directory to 3.

```
> 2:inode; 7:dir=3
```

**EXAMPLE 11** Using fsdb to change the name field

The following command changes the *name* field in the directory slot to name.

```
> 7:dir:nm="name"
```

**EXAMPLE 12** Using fsdb to display the a block

The following command displays the 3rd block of the current inode as directory entries.

**EXAMPLE 13** Using fsdb to set the contents of address

The following command sets the contents of address 2050 to 0xffffffff. 0xffffffff can be truncated, depending on the current type.

```
> 2050=0xffff
```

**EXAMPLE 14** Using fsdb to place an ASCII string at an address

The following command places the ASCII string *this is some text* at address 1c92434.

```
> 1c92434="this is some text"
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWudf         |

| <b>NAME</b>        | fsdb_ufs – ufs file system debugger                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <b>fsdb</b> -F ufs [ <i>generic_options</i> ] [ <i>specific_options</i> ] <i>special</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <code>fsdb_ufs</code> command is an interactive tool that can be used to patch up a damaged UFS file system. It has conversions to translate block and i-numbers into their corresponding disk addresses. Also included are mnemonic offsets to access different parts of an inode. These greatly simplify the process of correcting control block entries or descending the file system tree.</p> <p><code>fsdb</code> contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking <code>fsdb</code> with the <code>-o</code> option or by the use of the <code>o</code> command.</p> <p><code>fsdb</code> reads a block at a time and will therefore work with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. Note that in order to modify any portion of the disk, <code>fsdb</code> must be invoked with the <code>w</code> option.</p> <p>Wherever possible, <code>adb</code>-like syntax was adopted to promote the use of <code>fsdb</code> through familiarity.</p> |
| <b>OPTIONS</b>     | <p>The following option is supported:</p> <ul style="list-style-type: none"><li>-o Specify UFS file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces). The options available are:<ul style="list-style-type: none"><li>? Display usage</li><li>o Override some error conditions</li><li>p='string' set prompt to string</li><li>w open for write</li></ul></li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>USAGE</b>       | <p>Numbers are considered hexadecimal by default. However, the user has control over how data is to be displayed or accepted. The <code>base</code> command will display or set the input/output base. Once set, all input will default to this base and all output will be shown in this base. The base can be overridden temporarily for input by preceding hexadecimal numbers with <code>'0x'</code>, preceding decimal numbers with <code>'0t'</code>, or octal numbers with <code>'0'</code>. Hexadecimal numbers beginning with <code>a-f</code> or <code>A-F</code> must be preceded with <code>'0x'</code> to distinguish them from commands.</p> <p>Disk addressing by <code>fsdb</code> is at the byte level. However, <code>fsdb</code> offers many commands to convert a desired inode, directory entry, block, superblock and so forth to a byte address. Once the address has been calculated, <code>fsdb</code> will record the result in dot (<code>.</code>).</p> <p>Several global values are maintained by <code>fsdb</code>:</p> <ul style="list-style-type: none"><li>■ the current base (referred to as <code>base</code>),</li></ul>                                                                                                     |

- the current address (referred to as `dot`),
- the current inode (referred to as `inode`),
- the current count (referred to as `count`),
- and the current type (referred to as `type`).

Most commands use the preset value of `dot` in their execution. For example,

```
> 2:inode
```

will first set the value of `dot` to 2, `'.'`, will alert the start of a command, and the `inode` command will set `inode` to 2. A count is specified after a `'.'`. Once set, `count` will remain at this value until a new command is encountered which will then reset the value back to 1 (the default). So, if

```
> 2000,400/X
```

is typed, 400 hex longs are listed from 2000, and when completed, the value of `dot` will be  $2000 + 400 * \text{sizeof}(\text{long})$ . If a RETURN is then typed, the output routine will use the current values of `dot`, `count`, and `type` and display 400 more hex longs. A `'*'` will cause the entire block to be displayed.

End of fragment, block and file are maintained by `fsdb`. When displaying data as fragments or blocks, an error message will be displayed when the end of fragment or block is reached. When displaying data using the `db`, `ib`, `directory`, or `file` commands an error message is displayed if the end of file is reached. This is mainly needed to avoid passing the end of a directory or file and getting unknown and unwanted results.

An example showing several commands and the use of RETURN would be:

```
> 2:ino; 0:dir?d
 or
> 2:ino; 0:db:block?d
```

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, any subsequent RETURN (or +, -) will advance to subsequent entries. Note that

```
> 2:inode; :ls
 or
> :ls /
```

is again synonymous.

## Expressions

The symbols recognized by `fsdb` are:

|        |                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|
| RETURN | update the value of <code>dot</code> by the current value of <code>type</code> and display using the current value of <code>count</code> . |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|

|                             |                                                                                                                                                                                                                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| #                           | numeric expressions may be composed of +, -, *, and % operators (evaluated left to right) and may use parentheses. Once evaluated, the value of <code>dot</code> is updated.                                                                                                                           |
| , <i>count</i>              | count indicator. The global value of <code>count</code> will be updated to <code>count</code> . The value of <code>count</code> will remain until a new command is run. A count specifier of '*' will attempt to show a <i>blocks's</i> worth of information. The default for <code>count</code> is 1. |
| ? <i>f</i>                  | display in structured style with format specifier <i>f</i> . See <code>FormattedOutput</code> .                                                                                                                                                                                                        |
| / <i>f</i>                  | display in unstructured style with format specifier <i>f</i> . See <code>FormattedOutput</code> .                                                                                                                                                                                                      |
| .                           | the value of <code>dot</code> .                                                                                                                                                                                                                                                                        |
| + <i>e</i>                  | increment the value of <code>dot</code> by the expression <i>e</i> . The amount actually incremented is dependent on the size of <code>type</code> :<br><br>$\text{dot} = \text{dot} + e * \text{sizeof}(\text{type})$ <p>The default for <i>e</i> is 1.</p>                                           |
| - <i>e</i>                  | decrement the value of <code>dot</code> by the expression <i>e</i> . See +.                                                                                                                                                                                                                            |
| * <i>e</i>                  | multiply the value of <code>dot</code> by the expression <i>e</i> . Multiplication and division don't use <code>type</code> . In the above calculation of <code>dot</code> , consider the <code>sizeof (type)</code> to be 1.                                                                          |
| % <i>e</i>                  | divide the value of <code>dot</code> by the expression <i>e</i> . See *.                                                                                                                                                                                                                               |
| < <i>name</i>               | restore an address saved in register <i>name</i> . <i>name</i> must be a single letter or digit.                                                                                                                                                                                                       |
| > <i>name</i>               | save an address in register <i>name</i> . <i>name</i> must be a single letter or digit.                                                                                                                                                                                                                |
| = <i>f</i>                  | display indicator. If <i>f</i> is a legitimate format specifier, then the value of <code>dot</code> is displayed using the format specifier <i>f</i> . See <code>FormattedOutput</code> . Otherwise, assignment is assumed. See =.                                                                     |
| = [ <i>s</i> ] [ <i>e</i> ] | assignment indicator. The address pointed to by <code>dot</code> has its contents changed to the value of the expression <i>e</i> or to the ASCII representation of the quoted (") string <i>s</i> . This may be useful for changing directory names or ASCII file information.                        |
| += <i>e</i>                 | incremental assignment. The address pointed to by <code>dot</code> has its contents incremented by expression <i>e</i> .                                                                                                                                                                               |
| -= <i>e</i>                 | decremental assignment. The address pointed to by <code>dot</code> has its contents decremented by expression <i>e</i> .                                                                                                                                                                               |

**Commands** | A command must be prefixed by a ':' character. Only enough letters of the command to uniquely distinguish it are needed. Multiple commands may be entered on one line by separating them by a SPACE, TAB or ';'.

In order to view a potentially unmounted disk in a reasonable manner, `fsdb` offers the `cd`, `pwd`, `ls` and `find` commands. The functionality of these commands substantially matches those of its UNIX counterparts. See individual commands for details. The '\*', '?', and '[' wild card characters are available.

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>base=b</code>                       | display or set base. As stated above, all input and output is governed by the current base. If the <code>=b</code> is omitted, the current base is displayed. Otherwise, the current base is set to <i>b</i> . Note that this is interpreted using the old value of <code>base</code> , so to ensure correctness use the '0', '0t', or '0x' prefix when changing the <code>base</code> . The default for <code>base</code> is hexadecimal. |
| <code>block</code>                        | convert the value of <code>dot</code> to a block address.                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>cd dir</code>                       | change the current directory to directory <i>dir</i> . The current values of <code>inode</code> and <code>dot</code> are also updated. If no <i>dir</i> is specified, then change directories to inode 2 ("/").                                                                                                                                                                                                                            |
| <code>cg</code>                           | convert the value of <code>dot</code> to a cylinder group.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>directory</code>                    | If the current <code>inode</code> is a directory, then the value of <code>dot</code> is converted to a directory slot offset in that directory and <code>dot</code> now points to this entry.                                                                                                                                                                                                                                              |
| <code>file</code>                         | the value of <code>dot</code> is taken as a relative block count from the beginning of the file. The value of <code>dot</code> is updated to the first byte of this block.                                                                                                                                                                                                                                                                 |
| <code>find dir [-name n] [-inum i]</code> | find files by name or i-number. <code>find</code> recursively searches directory <i>dir</i> and below for filenames whose i-number matches <i>i</i> or whose name matches pattern <i>n</i> . Note that only one of the two options ( <code>-name</code> or <code>-inum</code> ) may be used at one time. Also, the <code>-print</code> is not needed or accepted.                                                                          |
| <code>fill=p</code>                       | fill an area of disk with pattern <i>p</i> . The area of disk is delimited by <code>dot</code> and <code>count</code> .                                                                                                                                                                                                                                                                                                                    |

fsdb\_ufs(1M)

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fragment  | convert the value of <i>dot</i> to a fragment address. The only difference between the <code>fragment</code> command and the <code>block</code> command is the amount that is able to be displayed.                                                                                                                                                                                                                                                                                                             |
| inode     | convert the value of <i>dot</i> to an inode address. If successful, the current value of <code>inode</code> will be updated as well as the value of <i>dot</i> . As a convenient shorthand, if <code>'inode'</code> appears at the beginning of the line, the value of <i>dot</i> is set to the current <code>inode</code> and that inode is displayed in inode format.                                                                                                                                         |
| log_chk   | run through the valid log entries without printing any information and verify the layout.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| log_delta | count the number of deltas into the log, using the value of <i>dot</i> as an offset into the log. No checking is done to make sure that offset is within the head/tail offsets.                                                                                                                                                                                                                                                                                                                                 |
| log_head  | display the header information about the file system logging. This shows the block allocation for the log and the data structures on the disk.                                                                                                                                                                                                                                                                                                                                                                  |
| log_otodb | return the physical disk block number, using the value of <i>dot</i> as an offset into the log.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| log_show  | display all deltas between the beginning of the log (BOL) and the end of the log (EOL).                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ls        | [ <code>-R</code> ] [ <code>-l</code> ] <i>pat1 pat2</i> . . . list directories or files. If no file is specified, the current directory is assumed. Either or both of the options may be used (but, if used, <i>must</i> be specified before the filename specifiers). Also, as stated above, wild card characters are available and multiple arguments may be given. The long listing shows only the i-number and the name; use the <code>inode</code> command with <code>'i'</code> to get more information. |
| override  | toggle the value of <code>override</code> . Some error conditions may be overridden if <code>override</code> is toggled on.                                                                                                                                                                                                                                                                                                                                                                                     |

|                 |                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prompt <i>p</i> | change the fsdb prompt to <i>p</i> . <i>p</i> must be surrounded by ("")s.                                                                                                                                                                                                      |
| pwd             | display the current working directory.                                                                                                                                                                                                                                          |
| quit            | quit fsdb.                                                                                                                                                                                                                                                                      |
| sb              | the value of <i>dot</i> is taken as a cylinder group number and then converted to the address of the superblock in that cylinder group. As a shorthand, 'sb' at the beginning of a line will set the value of <i>dot</i> to the superblock and display it in superblock format. |
| shadow          | if the current inode is a shadow inode, then the value of <i>dot</i> is set to the beginning of the shadow inode data.                                                                                                                                                          |
| !               | escape to shell                                                                                                                                                                                                                                                                 |

**Inode Commands**

In addition to the above commands, there are several commands that deal with inode fields and operate directly on the current inode (they still require the ':'). They may be used to more easily display or change the particular fields. The value of *dot* is only used by the ':db' and ':ib' commands. Upon completion of the command, the value of *dot* is changed to point to that particular field. For example,

```
> :ln+=1
```

would increment the link count of the current inode and set the value of *dot* to the address of the link count field.

at        access time.

bs        block size.

ct        creation time.

db        use the current value of *dot* as a direct block index, where direct blocks number from 0 - 11. In order to display the block itself, you need to 'pipe' this result into the block or fragment command. For example,

```
> 1:db:block,20/X
```

would get the contents of data block field 1 from the inode and convert it to a block address. 20 longs are then displayed in hexadecimal. See `FormattedOutput`.

gid        group id.

ib        use the current value of *dot* as an indirect block index where indirect blocks number from 0 - 2. This will only get the indirect block itself (the block containing the pointers to the actual blocks). Use the file command and start at block 12 to get to the actual blocks.

## fsdb\_ufs(1M)

ln link count.  
mt modification time.  
md mode.  
maj major device number.  
min minor device number.  
nm although listed here, this command actually operates on the directory name field. Once poised at the desired directory entry (using the *directory* command), this command will allow you to change or display the directory name. For example,  
  
    > 7:dir:nm="foo"  
  
will get the 7th directory entry of the current inode and change its name to foo. Note that names cannot be made larger than the field is set up for. If an attempt is made, the string is truncated to fit and a warning message to this effect is displayed.  
si shadow inode.  
sz file size.  
uid user id.

### Formatted Output

There are two styles and many format types. The two styles are structured and unstructured. Structured output is used to display inodes, directories, superblocks and the like. Unstructured displays raw data. The following shows the different ways of displaying:

?  
  
    c display as cylinder groups  
    i display as inodes  
    d display as directories  
    s display as superblocks  
    S display as shadow inode data  
  
/  
  
    b display as bytes  
    c display as characters  
    o O display as octal shorts or longs  
    d D display as decimal shorts or longs  
    x X display as hexadecimal shorts or longs The format specifier

immediately follows the '/' or '?' character. The values displayed by '/b' and all '?' formats are displayed in the current base. Also, type is appropriately updated upon completion.

**EXAMPLES****EXAMPLE 1** Displaying in Decimal

The following command displays 2010 in decimal (use of fsdb as a calculator for complex arithmetic):

```
> 2000+400% (20+20) =D
```

**EXAMPLE 2** Displaying an i-number in Inode Format

The following command displays i-number 386 in an inode format. This now becomes the current inode:

```
> 386:ino?i
```

**EXAMPLE 3** Changing the Link Count

The following command changes the link count for the current inode to 4:

```
> :ln=4
```

**EXAMPLE 4** Incrementing the Link Count

The following command increments the link count by 1:

```
> :ln+=1
```

**EXAMPLE 5** Displaying the Creation Time

The following command displays the creation time as a hexadecimal long:

```
> :ct=X
```

**EXAMPLE 6** Displaying the Modification Time

The following command displays the modification time in time format:

```
> :mt=t
```

**EXAMPLE 7** Displaying in ASCII

The following command displays in ASCII, block zero of the file associated with the current inode:

```
> 0:file/c
```

**EXAMPLE 8** Displaying the First Block's Worth of Directory Entries

The following command displays the first block's worth of directory entries for the root inode of this file system. It will stop prematurely if the EOF is reached:

```
> 2:ino,*?d
```

**EXAMPLE 9** Displaying Changes to the Current Inode

The following command displays changes the current inode to that associated with the 5th directory entry (numbered from zero) of the current inode. The first logical block of the file is then displayed in ASCII:

```
> 5:dir:inode; 0:file,*/c
```

**EXAMPLE 10** Displaying the Superblock

The following command displays the superblock of this file system:

```
> :sb
```

**EXAMPLE 11** Displaying the Cylinder Group

The following command displays cylinder group information and summary for cylinder group 1:

```
> 1:cg?c
```

**EXAMPLE 12** Changing the i-number

The following command changes the i-number for the seventh directory slot in the root directory to 3:

```
> 2:inode; 7:dir=3
```

**EXAMPLE 13** Displaying as Directory Entries

The following command displays the third block of the current inode as directory entries:

```
> 2:db:block,*?d
```

**EXAMPLE 14** Changing the Name Field

The following command changes the name field in the directory slot to *name*:

```
> 7:dir:nm="name"
```

**EXAMPLE 15** Getting and Filling Elements

The following command gets fragment 3c3 and fill 20 type elements with 0x20:

```
> 3c3:fragment,20:fill=0x20
```

**EXAMPLE 16** Setting the Contents of an Address

The following command sets the contents of address 2050 to 0xffffffff. 0xffffffff may be truncated depending on the current type:

```
> 2050=0xfffff
```

**EXAMPLE 17** Placing ASCII

The following command places the ASCII for the string at 1c92434:

```
> 1c92434="this is some text"
```

**EXAMPLE 18** Displaying Shadow Inode Data

The following command displays all of the shadow inode data in the shadow inode associated with the root inode of this file system:

```
> 2:ino:si:ino;0:shadow,*?S
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `clri(1M)`, `fsck_ufs(1M)`, `dir_ufs(4)`, `fs_ufs(4)`, `attributes(5)`

**WARNINGS** Since `fsdb` reads the disk raw, extreme caution is advised in determining its availability of `fsdb` on the system. Suggested permissions are 600 and owned by bin.

**NOTES** The old command line syntax for clearing i-nodes using the ufs-specific ' -z i-number ' option is still supported by the new debugger, though it is obsolete and will be removed in a future release. Use of this flag will result in correct operation, but an error message will be printed warning of the impending obsolescence of this option to the command. The equivalent functionality is available using the more flexible `clri(1M)` command.

fsirand(1M)

**NAME** fsirand – install random inode generation numbers

**SYNOPSIS** **fsirand** [-p] *special*

**DESCRIPTION** *fsirand* installs random inode generation numbers on all the inodes on device *special*, and also installs a file system ID in the superblock. This helps increase the security of file systems exported by NFS.

*fsirand* must be used only on an unmounted file system that has been checked with *fsck(1M)*. The only exception is that it can be used on the root file system in single-user mode, if the system is immediately re-booted afterwards.

**OPTIONS** -p Print out the generation numbers for all the inodes, but do not change the generation numbers.

**USAGE** See *largefile(5)* for the description of the behavior of *fsirand* when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** *fsck(1M)*, *attributes(5)*, *largefile(5)*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | fssnap – create temporary snapshots of a file system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre> /usr/sbin/fssnap [-F FSType] [-V] -o special_options [mount-point   special ] /usr/sbin/fssnap -d [-F FSType] [-V] -o special_options [mount-point   special ] /usr/sbin/fssnap -i [-F FSType] [-V] -o special_options [mount-point   special] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>The <code>fssnap</code> command creates a stable, read-only snapshot of a file system when given either an active mount point or a special device containing a mounted file system, as in the first form of the synopsis. A snapshot is a temporary image of a file system intended for backup operations.</p> <p>While the snapshot file system is stable and consistent, an application updating files when the snapshot is created might leave these files in an internally inconsistent, truncated, or otherwise unusable state. In such a case, the snapshot will contain these partially written or corrupted files. It is a good idea to ensure active applications are suspended or checkpointed and their associated files are also consistent during snapshot creation.</p> <p>Note that file access times are not updated while the snapshot is being created.</p> <p>A path to the virtual device that contains this snapshot is printed to standard output when a snapshot is created.</p>                                                                                                                                                           |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-d                       Deletes the snapshot associated with the given file system.</li> <li>-F <i>FSType</i>               Specifies the file system type to be used. The <i>FSType</i> should either be specified here or be determined by matching the block special device with an entry in the <code>/etc/vfstab</code> table, or by consulting <code>/etc/default/fs</code>.</li> <li>-i                       Displays the state of any given <i>FSType</i> snapshot. If a mount-point or device is not given, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default. The format and meaning of this information is file-system dependent. See the <i>FSType</i>-specific <code>fssnap</code> man page for details.</li> <li>-o <i>special_options</i>      See the <i>FSType</i>-specific man page for <code>fssnap</code>.</li> <li>-V                       Echoes the complete command line, but does not execute the command.</li> </ul> |

fssnap(1M)

**OPERANDS** The following operands are supported:  
*mount-point* The directory where the file system resides.  
*special* The physical device for the system, such as `/dev/dsk/c0t0d0s7`.

**EXAMPLES** See `FSType`-specific man pages for examples.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES** `/etc/vfstab` Specifies file system type.  
`/etc/default/fs` Specifies the default local file system type.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `fssnap_ufs(1M)`, `attributes(5)`

**NOTES** This command might not be supported for all `FSTypes`.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>NAME</b>        | fssnap_ufs – create a temporary snapshot of a UFS file system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre><b>fssnap</b> [-F] [ufs] [generic-options] -o backing-store=path, [specific-options] mount-point   special  <b>fssnap</b> [-F ufs] [-d] [generic-options] [-o specific-options] mount-point   special  <b>fssnap</b> [-F ufs] [-i] [generic-options] [-o specific-options] mount-point   special</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>The <code>fssnap</code> command queries, creates, or deletes a temporary snapshot of a UFS file system. A snapshot is a point-in-time image of a file system that provides a stable and unchanging device interface for backups.</p> <p>When creating a file system snapshot, you must specify the file system to be captured and the backing-store file.</p> <p>The backing-store file is one in which the snapshot subsystem saves old file system data before it is overwritten. The destination path must have enough free space to hold the backing-store file, whose size varies with the amount of activity on the file system. This location must be different from the file system that is being captured in a snapshot. The backing-store file can reside on any type of file system, including another UFS file system or an NFS-mounted file system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-d</code><br/>Deletes the snapshot associated with the given file system.</p> <p><code>-i</code><br/>Displays the state of one or all UFS snapshots. If a mount-point or device is not specified, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default.</p> <p>Use the <code>-o</code> options with the <code>-i</code> option to specify what snapshot information is displayed. Since this feature is provided primarily for use in scripts and on the command line, no labels are displayed for the data. Sizes are all in bytes, and the output is not internationalized or localized. The information is displayed on one line per option. Unrecognized options display a single <code>?</code> on the line. One line per option guarantees that there are the same number of lines as options specified and there is a one-to-one correspondence between an output line and an option.</p> <p>The following <code>-o</code> options display specific information for a given snapshot. See the <b>EXAMPLES</b> section for examples of how to use these options.</p> <p><code>snapnumber</code><br/>Display the snapshot number.</p> <p><code>blockdevname</code><br/>Display the block device path.</p> |

rawdevname

Display the raw device path.

mountpoint

Display the mount point of the master file system.

state

Display the state of the snapshot device.

backing-store

Display the location of the backing-store file.

backing-store-len

Display the size of the backing-store file.

maxsize

Display the max size of the backing-store file.

createtime

Display the time that the snapshot was created.

chunksize

Display the copy-on-write granularity.

-o *specific-options*

Without `-d` or `-i`, the default action is to create a snapshot. Specify the following options when creating a snapshot. All of these options are discretionary, except for the backing-store file (`bs`), which is required.

`backing-store=path`

Uses *path* as the backing-store file. *path* must not reside on the file system that is being captured in a snapshot.

*path* must exist, and must be either a directory, a regular file, or a raw device. If *path* is a directory, then a temporary file is created and held open. That device is then used as-is. The option can be abbreviated as `bf=path` or `bs=path`.

`unlink`

Unlinks the backing-store file after the snapshot is created. This option specifies that the backing-store file does not need to be removed manually when the snapshot is deleted. This might make administration more difficult since the file is not visible in the file system. If this option is not specified, the backing-store files should be removed manually after the snapshot is deleted.

`chunksize=n [k,m,g]`

Uses *n* for the chunk size. Chunk size is the granularity of the data that is sent to the backing store.

Specify `chunksize` in the following units: `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. By default, chunk size is four times the block size of the file system (typically 32k).

`maxsize=n[k,m,g]`

Does not allow the size of the backing-store file to exceed *n*, where *n* is the unit specified. The snapshot is deleted automatically when the backing-store file exceeds `maxsize`.

Specify `maxsize` in the following units: `k` for kilobytes, `m` for megabytes, or `g` for gigabytes.

`raw`

Displays to standard output the name of the raw device instead of the block device when a snapshot is created. The block device is printed by default (when `raw` is not specified). This option makes it easier to embed `fssnap` commands in the command line for commands that require the raw device instead. Both devices are always created. This option affects only the output.

**OPERANDS** The following operands are supported:

*mount-point* The directory where the file system resides.

*special* The physical device for the file system, such as `/dev/dsk/c0t0d0s7`.

**EXAMPLES** **EXAMPLE 1** Creating a Snapshot of a File System

The following example creates a snapshot of a file system. The block special device created for the snapshot is `/dev/fssnap/0`.

```
fssnap -F ufs -o backing-store=/var/tmp /export/home
/dev/fssnap/0
```

**EXAMPLE 2** Backing Up a File System Snapshot Without Having To Unmount the File System

The following example backs up a file system snapshot without having to unmount the file system. Since `ufsdump` requires the path to a raw device, the `raw` option is used. The `/export/home` file system snapshot is removed in the second command.

```
ufsdump 0uf /dev/rmt/0 `fssnap -F ufs
-o raw,bs=/dev/rdisk/c0t3d0s6 /export/home`
<output from ufsdump>
fssnap -F ufs -d /export/home
```

**EXAMPLE 3** Backing Up a File System

When backing up a file system, do not let the backing-store file exceed 400 Mbytes. The second command removes the `/export/home` file system snapshot.

```
ufsdump 0uf /dev/rmt/0 `fssnap -F ufs
-o maxsize=400m,backing-store=/export/snap,raw
/export/home`
fssnap -F ufs -d /export/home
```

**EXAMPLE 3** Backing Up a File System (Continued)**EXAMPLE 4** Performing an Incremental Dump of a Snapshot

The following example uses `ufsdump` to back up a snapshot of `/dev/rdisk/c0t3d0s2`. Note the use of the `N` option to `ufsdump`, which writes the name of the device being dumped, rather than the name of the snapshot device, to `/etc/dumpdates` file. See `ufsdump(1M)` for details on the `N` flag.

```
ufsdump lfNu /dev/rmt/0 /dev/rdisk/c0t3d0s2 `fssnap -F ufs
-o raw,bs=/export/scratch,unlink /dev/rdisk/c0t3d0s2`
```

**EXAMPLE 5** Finding Out What Snapshots Currently Exist

The following command displays the currently existing snapshots.

```
fssnap -i
0 /src
1 /export/home
<output continues>
```

**EXAMPLE 6** Mounting a File System Snapshot

The following example creates a file system snapshot. After you create a file system snapshot, mount it on `/tmp/mount` for temporary read-only access.

```
fssnap -F ufs -o backing-store=/nfs/server/scratch /export/home
/dev/fssnap/1
mkdir /tmp/mount
mount -F ufs -o ro /dev/fssnap/1 /tmp/mount
```

**EXAMPLE 7** Creating a File System Snapshot and Unlinking the Backing-store File

The following example creates a file system snapshot and unlinks the backing-store file. After creating a file system snapshot and unlinking the backing-store file, check the state of the snapshot.

```
fssnap -o bs=/scratch,unlink /src
/dev/fssnap/0
fssnap -i /src
Snapshot number : 0
Block Device : /dev/fssnap/0
Raw Device : /dev/xfssnap/0
Mount point : /src
Device state : active
Backing store path : /scratch/snapshot2 <UNLINKED>
Backing store size : 192 KB
Maximum backing store size : Unlimited
Snapshot create time : Sat May 06 10:55:11 2000
Copy-on-write granularity : 32 KB
```

**EXAMPLE 7** Creating a File System Snapshot and Unlinking the Backing-store File  
(Continued)

**EXAMPLE 8** Displaying the Size and Location of the Backing-store File and the Creation Time for the Snapshot

The following example displays the size of the backing-store file in bytes, the location of the backing store, and the creation time for the snapshot of the /test file system.

```
fssnap -i -o backing-store-len,backing-store,createtime /test
196608
/snapshot2
Sat May 6 10:55:11 2000
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

The script-readable output mode is a stable interface that can be added to, but will not change. All other interfaces are subject to change.

**NOTES** The `fssnap` device files should be treated like a regular disk block or character device.

The association between a file system and the snapshot is lost when the snapshot is deleted or the system reboots. Snapshot persistence across reboots is not currently supported.

To avoid unnecessary performance impacts, perform the snapshot and system backup when the system is least active.

## fstyp(1M)

| <b>NAME</b>        | fstyp – determine file system type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>fstyp</b> [-v] <i>special</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>fstyp allows the user to determine the file system type of unmounted file systems using heuristic programs.</p> <p>An <code>fstyp</code> module for each file system type to be checked is executed; each of these modules applies an appropriate heuristic to determine whether the supplied <i>special</i> file is of the type for which it checks. If it is, the program prints on standard output the usual file system identifier for that type (for example, “ufs”) and exits with a return code of 0; if none of the modules succeed, the error message <code>unknown_fstyp</code> (no matches) is returned and the exit status is 1. If more than one module succeeds, the error message <code>unknown_fstyp</code> (multiple matches) is returned and the exit status is 2.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-v Produce verbose output. This is usually information about the file systems superblock and varies across different <i>FSTypes</i>. See <code>fs_ufs(4)</code>, <code>mkfs_ufs(1M)</code>, and <code>tunefs(1M)</code> for details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of <code>fstyp</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

| <b>NAME</b>        | ftppaddhost – set up a virtual FTP host                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <b>ftppaddhost</b> -c   -l [-b] [-x <i>xferlog</i> ] <i>hostname</i> <i>root_dir</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | The <code>ftppaddhost</code> script is executed by the super user to set up virtual FTP hosts. The <code>ftppaddhost</code> command configures the virtual host <i>hostname</i> under directory <i>root_dir</i> . The value of <i>hostname</i> can be an IP address or the name of a host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>The <code>ftppaddhost</code> script supports the following options:</p> <ul style="list-style-type: none"> <li>-b            Create a banner for the virtual host. This option is useful to confirm that the virtual host is working.</li> <li>-c            Configure complete virtual hosting. This option allows each virtual host to have its own version of the <code>ftppaccess</code>, <code>ftppconversions</code>, <code>ftppgroups</code>, <code>ftpphosts</code>, and <code>ftppusers</code> files. The master version of each of these configuration files is copied from the <code>/etc/ftpd</code> directory and placed in the <code>/etc/ftpd/virtual-ftpd/<i>hostname</i></code> directory. If the <code>/etc/ftppusers</code> file exists it is appended to the virtual <code>ftppusers</code> file. If a virtual host lacks its own version of a configuration file, the master version is used.</li> <li>-l            Configure limited virtual hosting. This option allows a small number of parameters to be configured differently for a virtual host. See the <code>virtual</code> keyword on the <code>ftppaccess(4)</code> manual page.</li> <li>-x <i>xferlog</i>   Create a logfile entry such that the transfer logs for the virtual host are written to the specified file. An absolute path must be specified for the <i>xferlog</i> file.</li> </ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><i>hostname</i>        The host name or IP address of the virtual server.</li> <li><i>root_dir</i>         The absolute pathname of the directory under which the virtual server is set up.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>DESCRIPTION</b> | <p>The <code>ftpconfig</code> script is executed by the super user to set up anonymous FTP. Anonymous FTP allows users to remotely log on to the FTP server by specifying the user name <code>ftp</code> or <code>anonymous</code> and the user's email address as password. The anonymous users are logged on to the FTP Server and given access to a restricted file area with its own file system root. See <code>chroot(2)</code>. The FTP area has its own minimal system files.</p> <p>This command will copy and set up all the components needed to operate an anonymous FTP server, including creating the <code>ftp</code> user account, creating device nodes, copying <code>/usr/lib</code> files, and copying timezone data. The <code>passwd</code> and <code>group</code> files set up have been stripped down to prevent malicious users from finding login names on the server. The anonymous file area will be placed under <code>ftpd</code>dir. If the <code>ftp</code> user account already exists, then the current FTP area is used, and the system files in it are updated. All other files are left untouched. This command should be run to update the anonymous FTP area's configuration whenever a system patch is installed, or the system is upgraded.</p> |                |                 |              |          |
| <b>OPTIONS</b>     | -d        Create a new or update an existing <i>ftpd</i> dir without creating or updating the <i>ftp</i> user account. Use this option when creating guest FTP user accounts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |          |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>ftpd</i>dir    The absolute pathname of the directory under which the anonymous FTP area is set up.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |          |

| <b>SYNOPSIS</b>    | <b>ftprestart</b> [-V]                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |          |
| <b>DESCRIPTION</b> | Use the <code>ftprestart</code> command to restart an FTP Server previously shut down by means of <code>ftpshut(1M)</code> . The <code>ftprestart</code> command reads the shutdown capability from the <code>ftpaccess(4)</code> file to determine the path of the shutdown message files. It then reenables the FTP Server by removing any shutdown message files in the anonymous and virtual FTP Server area, as well as the system wide shutdown message file. |                |                 |              |          |
| <b>OPTIONS</b>     | The <code>ftprestart</code> command supports the following options:<br>-V            Display program copyright and version information, then terminate.                                                                                                                                                                                                                                                                                                             |                |                 |              |          |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> Sample Output from <code>ftprestart</code><br><br>The following example shows sample output from the <code>ftprestart</code> command:<br><br>example% <b>ftprestart</b><br>ftprestart: /export/home/ftp/etc/ftpd/shutdown.msg removed.<br>ftprestart: /export/home/virtual1/etc/ftpd/shutdown.msg removed.<br>ftprestart: /etc/ftpd/shutdown.msg removed.                                                                                          |                |                 |              |          |

| <b>NAME</b>        | ftpshtut – close down the FTP Servers at a given time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |    |                                                                    |    |                                          |    |                                               |    |                                |    |                                                                  |    |                                                       |    |                      |    |                                                    |    |                                            |    |                       |    |                                                 |    |                                   |
| <b>SYNOPSIS</b>    | <b>ftpshtut</b> [-V] [-v] [-l <i>min</i> ] [-d <i>min</i> ] <i>time</i> [ <i>warning-message...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |    |                                                                    |    |                                          |    |                                               |    |                                |    |                                                                  |    |                                                       |    |                      |    |                                                    |    |                                            |    |                       |    |                                                 |    |                                   |
| <b>DESCRIPTION</b> | <p>The ftpshtut command provides an automated shutdown procedure that the superuser can use to notify FTP users when the FTP Server is shutting down.</p> <p>Ten minutes before shutdown, or immediately if the value of <i>time</i> is less than ten minutes, any new FTP Server connections will be disabled. You may adjust the shutdown of new FTP Server connections by means of the -l option.</p> <p>Five minutes before shutdown, or immediately if the value of <i>time</i> is less than five minutes, all current FTP connections will be disconnected. You may adjust the shutdown of current FTP connections by means of the -d option.</p> <p>The ftpshtut command creates shutdown message files that the FTP Server uses to determine when to shutdown. Separate shutdown message files are created in the anonymous and virtual host FTP Server areas, in addition to the system wide shutdown message file. Once the shutdown occurs, the server continues to refuse connections until the appropriate shutdown message file is removed. This normally is done by using the ftprestart(1M) command. The location of the shutdown message file is specified by the shutdown capability in the ftpaccess file.</p> <p>The following magic cookies are available:</p> <table border="0" style="margin-left: 20px;"> <tr><td>%s</td><td>The time system is going to shut down.</td></tr> <tr><td>%r</td><td>The time new connections will be denied.</td></tr> <tr><td>%d</td><td>The time current connections will be dropped.</td></tr> <tr><td>%C</td><td>The current working directory.</td></tr> <tr><td>%E</td><td>The maintainer's email address as defined in the ftpaccess file.</td></tr> <tr><td>%F</td><td>The free space in the partition of CWD, in kilobytes.</td></tr> <tr><td>%L</td><td>The local host name.</td></tr> <tr><td>%M</td><td>The maximum allowed number of users in this class.</td></tr> <tr><td>%N</td><td>The current number of users in this class.</td></tr> <tr><td>%R</td><td>The remote host name.</td></tr> <tr><td>%T</td><td>The local time (form Thu Nov 15 17:12:42 1990).</td></tr> <tr><td>%U</td><td>The username given at login time.</td></tr> </table> | %s | The time system is going to shut down.                             | %r | The time new connections will be denied. | %d | The time current connections will be dropped. | %C | The current working directory. | %E | The maintainer's email address as defined in the ftpaccess file. | %F | The free space in the partition of CWD, in kilobytes. | %L | The local host name. | %M | The maximum allowed number of users in this class. | %N | The current number of users in this class. | %R | The remote host name. | %T | The local time (form Thu Nov 15 17:12:42 1990). | %U | The username given at login time. |

## ftpshtut(1M)

- d *min* The time ahead of shutdown, in minutes, that existing connections will be disconnected upon completion of their current or next (if idle) FTP request.
- l *min* The time ahead of shutdown, in minutes, that new connections will be refused.
- v Verbose. Output the pathname of the shutdown message files created.

**OPERANDS** The ftpshut command supports the following operands:

*time* The *time* at which ftpshut will bring the FTP Servers down. *time* can have a value of *now*, which indicates an immediate shutdown. Alternatively, *time* can specify a future time in one of two formats: *+number* or *HHMM*. The first form brings the FTP Server down in *number* minutes. The second brings the FTP Server down at the time of day indicated, using a 24-hour clock format. When using the absolute time format, you can only specify times between now and 23:59.

*warning-message* The message to display that warns of the imminent shutdown. The *warning-message* will be formatted at 70 characters wide. ftpshut knows the actual string length of the magic cookies. If no *warning-message* is supplied, the default message "System shutdown at %s" is used.

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**FILES** /etc/ftpd/ftpaccess  
/etc/ftpd/ftpservers

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>NAME</b>        | fuser – identify processes using a file or file structure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/fuser [-c   -f] [-nu] [-k   -s sig]files [ [- ] [-c   -f] [-nu] [-k   -s sig]files] ...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>fuser displays the process IDs of the processes that are using the <i>files</i> specified as arguments.</p> <p>Each process ID is followed by a letter code. These letter codes are interpreted as follows: if the process is using the file as</p> <ul style="list-style-type: none"> <li>c        Indicates that the process is using the file as its current directory.</li> <li>m        Indicates that the process is using a file mapped with <code>mmap(2)</code>. See <code>mmap(2)</code> for details.</li> <li>n        Indicates that the process is holding a non-blocking mandatory lock on the file.</li> <li>o        Indicates that the process is using the file as an open file.</li> <li>r        Indicates that the process is using the file as its root directory.</li> <li>t        Indicates that the process is using the file as its text file.</li> <li>y        Indicates that the process is using the file as its controlling terminal.</li> </ul> <p>For block special devices with mounted file systems, all processes using any file on that device are listed. For all types of files (text files, executables, directories, devices, and so forth), only the processes using that file are reported.</p> <p>If more than one group of files are specified, the options may be respecified for each additional group of files. A lone dash cancels the options currently in force.</p> <p>The process IDs are printed as a single line on the standard output, separated by spaces and terminated with a single new line. All other output is written on standard error.</p> <p>Any user can run fuser, but only the superuser can terminate another user's process.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c        Reports on files that are mount points for file systems, and any files within that mounted file system.</li> <li>-f        Print a report for the named file, not for files within a mounted file system.</li> <li>-k        Sends the <code>SIGKILL</code> signal to each process. Since this option spawns kills for each process, the kill messages may not show up immediately (see <code>kill(2)</code>).</li> <li>-n        Lists only processes with non-blocking mandatory locks on a file.</li> <li>-s <i>sig</i>    Send a signal to each process. The <i>sig</i> option argument specifies one of the symbolic names defined in the <code>&lt;signal.h&gt;</code> header, or a decimal integer</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

fuser(1M)

signal number. If *sig* is a symbolic name, it is recognized in a case-independent fashion, without the SIG prefix. The -k option is equivalent to -s KILL or -s 9.

-u Displays the user login name in parentheses following the process ID.

**EXAMPLES**

**EXAMPLE 1** Reporting on the Mount Point and Files

The following example reports on the mount point and files within the mounted file system.

```
fuser -c /export/foo
```

**EXAMPLE 2** Restricting Output When Reporting on the Mount Point and Files

The following example reports on the mount point and files within the mounted file system, but the output is restricted to processes that hold non-blocking mandatory locks.

```
fuser -cn /export/foo
```

**EXAMPLE 3** Sending SIGTERM to Processes Holding a Non-Blocking Mandatory Lock

The following command sends SIGTERM to any processes that hold a non-blocking mandatory lock on file /export/foo/my\_file.

```
fuser -fn -s term /export/foo/my_file
```

**ENVIRONMENT VARIABLES**

See environ(5) for descriptions of the following environment variables that affect the execution of fuser: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

ps(1), mount(1M), kill(2), mmap(2), signal(3C), attributes(5), environ(5)

**NOTES**

Because fuser works with a snapshot of the system image, it may miss processes that begin using a file while fuser is running. Also, processes reported as using a file may have stopped using it while fuser was running. These factors should discourage the use of the -k option.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>NAME</b>        | fwtmp, wtmpfix – manipulate connect accounting records                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <code>/usr/lib/acct/fwtmp [-ic]</code><br><code>/usr/lib/acct/wtmpfix [file...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>fwtmp reads from the standard input and writes to the standard output, converting binary records of the type found in <code>/var/adm/wtmpx</code> to formatted ASCII records. The ASCII version is useful when it is necessary to edit bad records.</p> <p>wtmpfix examines the standard input or named files in utmpx format, corrects the time/date stamps to make the entries consistent, and writes to the standard output. A hyphen (-) can be used in place of <i>file</i> to indicate the standard input. If time/date corrections are not performed, acctcon(1M) will fault when it encounters certain date-change records.</p> <p>Each time the date is set, a pair of date change records are written to <code>/var/adm/wtmpx</code>. The first record is the old date denoted by the string "old time" placed in the <code>line</code> field and the flag <code>OLD_TIME</code> placed in the <code>type</code> field of the utmpx structure. The second record specifies the new date and is denoted by the string <code>new time</code> placed in the <code>line</code> field and the flag <code>NEW_TIME</code> placed in the <code>type</code> field. wtmpfix uses these records to synchronize all time stamps in the file.</p> <p>In addition to correcting time/date stamps, wtmpfix will check the validity of the <code>name</code> field to ensure that it consists solely of alphanumeric characters or spaces. If it encounters a name that is considered invalid, it will change the login name to <code>INVALID</code> and write a diagnostic to the standard error. In this way, wtmpfix reduces the chance that acctcon will fail when processing connect accounting records.</p> |
| <b>OPTIONS</b>     | <code>-ic</code> Denotes that input is in ASCII form, and output is to be written in binary form.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>NAME</b>        | <code>gencc</code> – create a front-end to the <code>cc</code> command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <code>gencc</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>gencc</code> command is an interactive command designed to aid in the creation of a front-end to the <code>cc</code> command. Since hard-coded pathnames have been eliminated from the C Compilation System (CCS), it is possible to move pieces of the CCS to new locations without recompilation. The new locations of moved pieces can be specified through the <code>-Y</code> option to the <code>cc</code> command. However, it is inconvenient to supply the proper <code>-Y</code> options with every invocation of the <code>cc</code> command. Further, if a system administrator moves pieces of the CCS, such movement should be invisible to users.</p> <p>The front-end to the <code>cc</code> command that <code>gencc</code> generates is a one-line shell script that calls the <code>cc</code> command with the proper <code>-Y</code> options specified. The front-end to the <code>cc</code> command will also pass all user-supplied options to the <code>cc</code> command.</p> <p><code>gencc</code> prompts for the location of each tool and directory that can be respecified by a <code>-Y</code> option to the <code>cc</code> command. If no location is specified, it assumes that that piece of the CCS has not been relocated. After all the locations have been prompted for, <code>gencc</code> will create the front-end to the <code>cc</code> command.</p> <p><code>gencc</code> creates the front-end to the <code>cc</code> command in the current working directory and gives the file the same name as the <code>cc</code> command. Thus, <code>gencc</code> can not be run in the same directory containing the actual <code>cc</code> command. Further, if a system administrator has redistributed the CCS, the actual <code>cc</code> command should be placed in a location that is not typically in a user's path (for example, <code>/usr/lib</code>). Such placement will prevent users from accidentally invoking the <code>cc</code> command without using the front-end.</p> |
| <b>FILES</b>       | <code>./cc</code> front-end to <code>cc</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | getdev – lists devices based on criteria                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <b>getdev</b> [-ae] [ <i>criteria...</i> ] [ <i>device...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>getdev generates a list of devices that match certain criteria. The criteria includes a list of attributes (given in expressions) and a list of devices. If no criteria are given, all devices are included in the list.</p> <p>Devices must satisfy at least one of the criteria in the list unless the -a option is used. Then, only those devices which match all of the criteria in a list will be included.</p> <p>Devices which are defined on the command line and which match the criteria are included in the generated list. However, if the -e option is used, the list becomes a set of devices to be <i>excluded</i> from the list. See <b>OPTIONS</b> and <b>OPERANDS</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-a        Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.</p> <p>-e        Specifies that the list of devices which follows on the command line should be <i>excluded</i> from the list generated by this command. Without the -e the named devices are <i>included</i> in the generated list. The flag has no effect if no devices are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>criteria</i>        Defines the criteria that a device must match to be included in the generated list. <i>criteria</i> is specified by expressions.</p> <p>                  There are four possible expression types which the criteria specified in the <i>criteria</i> argument may follow:</p> <p><i>attribute=value</i>        Selects all devices whose attribute <i>attribute</i> is defined and is equal to <i>value</i>.</p> <p><i>attribute!=value</i>        Selects all devices whose attribute <i>attribute</i> is defined and does not equal <i>value</i>.</p> <p><i>attribute:*</i>                Selects all devices which have the attribute <i>attribute</i> defined.</p> <p><i>attribute!:*</i>                Selects all devices which do not have the attribute <i>attribute</i> defined.</p> <p>                  See the putdev(1M) manual page for a complete listing and description of available attributes.</p> <p><i>device</i>                Defines the devices which should be included in the generated list. This can be the pathname of the device or the device alias.</p> |

getdev(1M)

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2 Device table could not be opened for reading.

**FILES** /etc/device.tab

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `devattr(1M)`, `getdgrp(1M)`, `putdev(1M)`, `putdgrp(1M)`, `attributes(5)`

| <b>NAME</b>              | getdgrp – lists device groups which contain devices that match criteria                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |
| <b>SYNOPSIS</b>          | <code>/usr/sbin/getdgrp [-ae1] [criteria...] [dgroup...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |
| <b>DESCRIPTION</b>       | getdgrp generates a list of device groups that contain devices matching the given criteria. The criteria is given in the form of expressions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |
| <b>OPTIONS</b>           | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a        Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.</li> <li>-e        Specifies that the list of device groups on the command line should be <i>excluded</i> from the list generated by this command. Without the -e option the named device groups are <i>included</i> in the generated list. The flag has no effect if no devices are defined.</li> <li>-1        Specifies that all device groups (subject to the -e option and the <i>dgroup</i> list) should be listed even if they contain no valid device members. This option has no affect if <i>criteria</i> is specified on the command line.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |
| <b>OPERANDS</b>          | <p>The following operands are supported:</p> <p><i>criteria</i>        Defines criteria that a device must match before a device group to which it belongs can be included in the generated list. Specify <i>criteria</i> as an expression or a list of expressions which a device must meet for its group to be included in the list generated by getdgrp. If no criteria are given, all device groups are included in the list.</p> <p>Devices must satisfy at least one of the criteria in the list. However, the -a option can be used to define that a "logical and" operation should be performed. Then, only those groups containing devices which match all of the criteria in a list will be included.</p> <p>There are four possible expressions types which the criteria specified in the <i>criteria</i> argument may follow:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><i>attribute=value</i></td> <td>Selects all device groups with a member whose attribute <i>attribute</i> is defined and is equal to <i>value</i>.</td> </tr> <tr> <td style="padding-right: 20px;"><i>attribute !=value</i></td> <td>Selects all device groups with a member whose attribute <i>attribute</i> is defined and does not equal <i>value</i>.</td> </tr> <tr> <td style="padding-right: 20px;"><i>attribute : *</i></td> <td>Selects all device groups with a member which has the attribute <i>attribute</i> defined.</td> </tr> </table> | <i>attribute=value</i> | Selects all device groups with a member whose attribute <i>attribute</i> is defined and is equal to <i>value</i> . | <i>attribute !=value</i> | Selects all device groups with a member whose attribute <i>attribute</i> is defined and does not equal <i>value</i> . | <i>attribute : *</i> | Selects all device groups with a member which has the attribute <i>attribute</i> defined. |

## getdgrp(1M)

*attribute!* : \*                      Selects all device groups with a member which does not have the attribute *attribute* defined.

See `putdev(1M)` for a complete listing and description of available attributes.

### *dgroup*

Defines a set of device groups which should be included in or excluded from the generated list. Device groups that are defined and which contain devices matching the criteria are included.

If the `-e` option is used, this list defines a set of device groups to be excluded. When the `-e` option is used and *criteria* is also defined, the generated list will include device groups containing devices which match the criteria and are not in the command line list.

**EXIT STATUS**    The following exit values are returned:

- 0            Successful completion of the task.
- 1            Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2            Device table or device group table could not be opened for reading.

**FILES**            `/etc/device.tab`  
`/etc/dgroup.tab`

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>SYNOPSIS</b>           | <b>getent</b> <i>database</i> [ <i>key...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                           |                                        |                    |               |                   |            |                        |                         |                          |                                  |                      |                               |                       |                        |                    |                                                 |                      |                       |
| <b>DESCRIPTION</b>        | <p>getent gets a list of entries from the administrative database specified by <i>database</i>. The information generally comes from one or more of the sources that are specified for the <i>database</i> in <i>/etc/nsswitch.conf</i>.</p> <p><i>database</i> is the name of the database to be examined. This can be <i>passwd</i>, <i>group</i>, <i>hosts</i>, <i>ipnodes</i>, <i>services</i>, <i>protocols</i>, <i>ethers</i>, <i>networks</i>, or <i>netmasks</i>. For each of these databases, getent uses the appropriate library routines described in <i>getpwnam(3C)</i>, <i>getgrnam(3C)</i>, <i>gethostbyaddr(3NSL)</i>, <i>gethostbyname(3NSL)</i>, <i>getipnodebyaddr(3SOCKET)</i>, <i>getipnodebyname(3SOCKET)</i>, <i>getservbyname(3SOCKET)</i>, <i>getprotobyname(3SOCKET)</i>, <i>ethers(3SOCKET)</i>, and <i>getnetbyname(3SOCKET)</i>, respectively.</p> <p>Each <i>key</i> must be in a format appropriate for searching on the respective database. For example, it can be a <i>username</i> or <i>numeric-uid</i> for <i>passwd</i>; <i>hostname</i> or <i>IP address</i> for <i>hosts</i>; or <i>service</i>, <i>service/protocol</i>, <i>port</i>, or <i>port/proto</i> for <i>services</i>.</p> <p>getent prints out the database entries that match each of the supplied keys, one per line, in the format of the matching administrative file: <i>passwd(4)</i>, <i>group(4)</i>, <i>hosts(4)</i>, <i>ipnodes(4)</i>, <i>services(4)</i>, <i>protocols(4)</i>, <i>ethers(3SOCKET)</i>, <i>networks(4)</i>, or <i>netmasks(4)</i>. If no key is given, all entries returned by the corresponding enumeration library routine, for example, <i>getpwent()</i> or <i>gethostent()</i>, are printed. Enumeration is not supported on <i>ipnodes</i>.</p> |                           |                                        |                    |               |                   |            |                        |                         |                          |                                  |                      |                               |                       |                        |                    |                                                 |                      |                       |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/gettable host</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |          |
| <b>DESCRIPTION</b> | <p>gettable is a simple program used to obtain the DoD Internet host table from a “hostname” server. The specified <i>host</i> is queried for the table. The table is placed in the file <code>hosts.txt</code>.</p> <p>gettable operates by opening a TCP connection to the port indicated in the service specification for “hostname”. A request is then made for all names and the resultant information is placed in the output file.</p> <p>gettable is best used in conjunction with the <code>htable(1M)</code> program which converts the DoD Internet host table format to that used by the network library lookup routines.</p> |                |                 |              |          |

| <b>NAME</b>        | getty – set terminal type, modes, speed, and line discipline                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <pre> /usr/lib/saf/ttymon [-h] [-t timeout] line [speed [type [linedisc]]] /usr/lib/saf/ttymon -c file </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>getty sets terminal type, modes, speed, and line discipline. <code>getty</code> is a symbolic link to <code>/usr/lib/saf/ttymon</code>. It is included for compatibility with previous releases for the few applications that still call <code>getty</code> directly.</p> <p><code>getty</code> can only be executed by the super-user, (a process with the user ID <code>root</code>). Initially <code>getty</code> prints the login prompt, waits for the user's login name, and then invokes the <code>login</code> command. <code>getty</code> attempts to adapt the system to the terminal speed by using the options and arguments specified on the command line.</p> <p>Without optional arguments, <code>getty</code> specifies the following: The <i>speed</i> of the interface is set to 300 baud, either parity is allowed, NEWLINE characters are converted to carriage return-line feed, and tab expansion is performed on the standard output. <code>getty</code> types the login prompt before reading the user's name a character at a time. If a null character (or framing error) is received, it is assumed to be the result of the user pressing the BREAK key. This will cause <code>getty</code> to attempt the next <i>speed</i> in the series. The series that <code>getty</code> tries is determined by what it finds in <code>/etc/ttydefs</code>.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-h                    If the -h flag is not set, a hangup will be forced by setting the speed to zero before setting the speed to the default or a specified speed.</li> <li>-t <i>timeout</i>        Specifies that <code>getty</code> should exit if the open on the line succeeds and no one types anything in <i>timeout</i> seconds.</li> <li>-c <i>file</i>            The -c option is no longer supported. Instead use <code>/usr/sbin/sttydefs -l</code> to list the contents of the <code>/etc/ttydefs</code> file and perform a validity check on the file.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><i>line</i>                The name of a TTY line in <code>/dev</code> to which <code>getty</code> is to attach itself. <code>getty</code> uses this string as the name of a file in the <code>/dev</code> directory to open for reading and writing.</li> <li><i>speed</i>              The <i>speed</i> argument is a label to a speed and TTY definition in the file <code>/etc/ttydefs</code>. This definition tells <code>getty</code> at what speed to run initially, what the initial TTY settings are, and what speed to try next, (should the user press the BREAK key to indicate that the speed is inappropriate). The default <i>speed</i> is 300 baud.</li> <li><i>type</i> and <i>linedisc</i>    These options are obsolete and will be ignored.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | getvol – verifies device accessibility                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>/usr/bin/getvol -n [-l <i>label</i>] <i>device</i><br/>/usr/bin/getvol [-f   -F] [-ow] [-l <i>label</i>   -x <i>label</i>] <i>device</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | getvol verifies that the specified device is accessible and that a volume of the appropriate medium has been inserted. The command is interactive and displays instructional prompts, describes errors, and shows required label information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-n Runs the command in non-interactive mode. The volume is assumed to be inserted upon command invocation.</li><li>-l <i>label</i> Specifies that the label <i>label</i> must exist on the inserted volume (can be overridden by the -o option).</li><li>-f Formats the volume after insertion, using the format command defined for this device in the device table.</li><li>-F Formats the volume after insertion and places a file system on the device. Also uses the format command defined for this device in the device table.</li><li>-o Allows the administrator to override a label check.</li><li>-w Allows administrator to write a new label on the device. User is prompted to supply the label text. This option is ineffective if the -n option is enabled.</li><li>-x <i>label</i> Specifies that the label <i>label</i> must exist on the device. This option should be used in place of the -l option when the label can only be verified by visual means. Use of the option causes a message to be displayed asking the administrator to visually verify that the label is indeed <i>label</i>.</li></ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"><li><i>device</i> Specifies the device to be verified for accessibility.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <ul style="list-style-type: none"><li>0 Successful completion.</li><li>1 Command syntax was incorrect, invalid option was used, or an internal error occurred.</li><li>3 Device table could not be opened for reading.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**FILES** /etc/device.tab

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `attributes(5)`

**NOTES** This command uses the device table to determine the characteristics of the device when performing the volume label checking.

| <b>NAME</b>        | gkadmin – Kerberos database administration GUI, SEAM Administration Tool                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/gkadmin</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p><code>gkadmin</code> is an interactive graphical user interface (GUI) that enables you to maintain Kerberos principals and policies. <code>gkadmin</code> provides much the same functionality as the <code>kadmin(1M)</code> command.</p> <p><code>gkadmin</code> does not support the management of keytabs. You must use <code>kadmin</code> for keytabs management. <code>gkadmin</code> uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network.</p> <p>When <code>gkadmin</code> is invoked, the login window is populated with default values. For the principal name, <code>gkadmin</code> determines your user name from the <code>USER</code> environment variable. It appends <code>/admin</code> to the name (<code>username/admin</code>) to create a default user instance in the same manner as <code>kadmin</code>. It also selects appropriate defaults for realm and master KDC (<code>admin_server</code>) from the <code>/etc/krb5/krb5.conf</code> file.</p> <p>You can change these defaults on the login window. When you enter your password, a session is started with <code>kadmin.d</code>. Operations performed are subject to permissions that are granted or denied to the chosen user instance by the Kerberos ACL file. See <code>kadm5.acl(4)</code>.</p> <p>After the session is started, a tabbed folder is displayed that contains a principal list and a policy list. The functionality is mainly the same as <code>kadmin</code>, with addition, deletion, and modification of principal and policy data available.</p> <p>In addition, <code>gkadmin</code> provides the following features:</p> <ul style="list-style-type: none"><li>■ New principal or policy records can be added either from default values or from the settings of an existing principal.</li><li>■ A comment field is available for principals.</li><li>■ Default values are saved in <code>\$HOME/.gkadmin</code>.</li><li>■ A logout option permits you to log back in as another user instance without exiting the tool.</li><li>■ Principal and policy lists and attributes can be printed or saved to a file.</li><li>■ Online context-sensitive help and general help is available in the <code>Help</code> menu.</li></ul> |                                                                                                                                                                                     |

| <b>NAME</b>        | groupadd – add (create) a new group definition on the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/groupadd [-g <i>gid</i> [-o]] <i>group</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | The groupadd command creates a new group definition on the system by adding the appropriate entry to the <code>/etc/group</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-g <i>gid</i></code> Assigns the group id <i>gid</i> for the new group. This group id must be a non-negative decimal integer below MAXUID as defined in <code>/usr/include/sys/param.h</code>. The group ID defaults to the next available (unique) number above the highest number currently assigned. For example, if groups 100, 105, and 200 are assigned as groups, the next default group number will be 201. (Group IDs from 0–99 are reserved by SunOS for future applications.)</p> <p><code>-o</code> Allows the <i>gid</i> to be duplicated (non-unique).</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>group</i> A string consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message will be written if the string exceeds MAXGLEN, which is usually set at eight characters. The <i>group</i> field must contain at least one character; it accepts lower case or numeric characters or a combination of both, and must not contain a colon (: ) or NEWLINE.</p>                                                                                                                                                        |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>2 Invalid command syntax. A usage message for the groupadd command is displayed.</p> <p>3 An invalid argument was provided to an option.</p> <p>4 The <i>gid</i> is not unique (when <code>-o</code> option is not used).</p> <p>9 The <i>group</i> is not unique.</p> <p>10 The <code>/etc/group</code> file cannot be updated.</p>                                                                                                                                                                                                        |
| <b>FILES</b>       | <code>/etc/group</code><br><code>/usr/include/userdefs.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

groupadd(1M)

**SEE ALSO** users(1B), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), useradd(1M), userdel(1M), usermod(1M), group(4), attributes(5)

**NOTES** groupadd only adds a group definition to the local system. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/group` file with additional entries, groupadd cannot change information supplied by the network name service. However, groupadd will verify the uniqueness of group name and group ID against the external name service.

groupdel(1M)

**NAME** groupdel – delete a group definition from the system

**SYNOPSIS** `/usr/sbin/groupdel group`

**DESCRIPTION** The `groupdel` utility deletes a group definition from the system. It deletes the appropriate entry from the `/etc/group` file.

**OPERANDS** `group` An existing group name to be deleted.

**EXIT STATUS** The following exit values are returned:

- 0 Success.
- 2 Invalid command syntax. A usage message for the `groupdel` command is displayed.
- 6 `group` does not exist.
- 10 Cannot update the `/etc/group` file.

**FILES** `/etc/group` system file containing group definitions

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `users(1B)`, `groupadd(1M)`, `groupmod(1M)`, `logins(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `attributes(5)`

**NOTES** The `groupdel` utility only deletes a group definition that is in the local `/etc/group` file. If a network nameservice such as NIS or NIS+ is being used to supplement the local `/etc/group` file with additional entries, `groupdel` cannot change information supplied by the network nameservice.

| <b>NAME</b>        | groupmod – modify a group definition on the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/groupmod [-g <i>gid</i> [-o]] [-n <i>name</i>] <i>group</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | The <code>groupmod</code> command modifies the definition of the specified group by modifying the appropriate entry in the <code>/etc/group</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-g <i>gid</i></code> Specify the new group ID for the group. This group ID must be a non-negative decimal integer less than <code>MAXUID</code>, as defined in <code>&lt;param.h&gt;</code>. The group ID defaults to the next available (unique) number above 99. (Group IDs from 0-99 are reserved by SunOS for future applications.)</p> <p><code>-n <i>name</i></code> Specify the new name for the group. The <i>name</i> argument is a string of no more than eight bytes consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept group fields that do not meet these requirements. The <i>name</i> argument must contain at least one character and must not include a colon (<code>:</code>) or NEWLINE (<code>\n</code>).</p> <p><code>-o</code> Allow the <i>gid</i> to be duplicated (non-unique).</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>group</i> An existing group name to be modified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>EXIT STATUS</b> | <p>The <code>groupmod</code> utility exits with one of the following values:</p> <p>0 Success.</p> <p>2 Invalid command syntax. A usage message for the <code>groupmod</code> command is displayed.</p> <p>3 An invalid argument was provided to an option.</p> <p>4 <i>gid</i> is not unique (when the <code>-o</code> option is not used).</p> <p>6 <i>group</i> does not exist.</p> <p>9 <i>name</i> already exists as a group name.</p> <p>10 Cannot update the <code>/etc/group</code> file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**NOTES** The groupmod utility only modifies group definitions in the `/etc/group` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/group` file with additional entries, groupmod cannot change information supplied by the network name service. The groupmod utility will, however, verify the uniqueness of group name and group ID against the external name service.

| <b>NAME</b>        | growfs – non-destructively expand a UFS file system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/growfs [-M <i>mount-point</i>] [<i>newfs-options</i>] [<i>raw-device</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>growfs non-destructively expands a mounted or unmounted UNIX file system (UFS) to the size of the file system's slice(s).</p> <p>Typically, disk space is expanded by first adding a slice to a metadvice, then running the growfs command. When adding space to a mirror, you expand each submirror before expanding the file system. On a trans metadvice, the master device is expanded, not the trans metadvice. Then the growfs command is run on the trans metadvice. (You can add space to a logging device, but you do not need to run the growfs command. The new space is automatically recognized.)</p> <p>growfs will "write-lock" (see lockfs(1M)) a mounted file system when expanding. The length of time the file system is write-locked can be shortened by expanding the file system in stages. For instance, to expand a 1 Gbyte file system to 2 Gbytes, the file system can be grown in 16 Mbyte stages using the -s option to specify the total size of the new file system at each stage. The argument for -s is the number of sectors, and must be a multiple of the cylinder size. Note: The file system cannot be grown if a cylinder size of less than 2 is specified. Refer to the newfs(1M) man page for information on the options available when growing a file system.</p> <p>growfs displays the same information as mkfs during the expansion of the file system.</p> <p>If growfs is aborted, recover any lost free space by unmounting the file system and running the fsck command, or run the growfs command again.</p> |
| <b>OPTIONS</b>     | <p>Root privileges are required for all of the following options.</p> <p><i>-M mount-point</i><br/>The file system to be expanded is mounted on <i>mount-point</i>. File system locking (lockfs) will be used.</p> <p><i>newfs-options</i><br/>The options are documented in the newfs man page.</p> <p><i>raw-device</i><br/>Specifies the name of a raw metadvice or raw special device, residing in <code>/dev/md/rdisk</code>, or <code>/dev/rdisk</code>, respectively, including the disk slice, where you want the file system to be grown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Expanding nonmetadvice slice for <code>/export</code> file system</p> <p>The following example expands a nonmetadvice slice for the <code>/export</code> file system. In this example, the existing slice, <code>/dev/dsk/c1t0d0s3</code>, is converted to a metadvice so additional slices can be concatenated.</p> <pre># metainit -f d8 2 1 c1t0d0s3 1 c2t0d0s3 # umount /export</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## growfs(1M)

### EXAMPLE 2 Associate /export with new metadvice

Edit the `/etc/vfstab` file to change the entry for `/export` to the newly defined metadvice, `d8`.

```
mount /export
growfs -M /export /dev/md/rdisk/d8
```

The first example starts by running the `metainit` command with the `-f` option to force the creation of a new concatenated metadvice `d8`, which consists of the existing slice `/dev/dsk/c1t0d0s3` and a new slice `/dev/dsk/c2t0d0s3`. Next, the file system on `/export` must be unmounted. The `/etc/vfstab` file is edited to change the entry for `/export` to the newly defined metadvice name, rather than the slice name. After the file system is remounted, the `growfs` command is run to expand the file system. The file system will span the entire metadvice when `growfs` completes. The `-M` option enables the `growfs` command to expand a mounted file system. During the expansion, write access for `/export` is suspended until `growfs` unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

### EXAMPLE 3 Dynamic Expansion of /export file system

The following example picks up from the previous one. Here, the `/export` file system mounted on metadvice `d8` is dynamically expanded.

```
metattach d8 c0t1d0s2
growfs -M /export /dev/md/rdisk/d8
```

This example begins by using the `metattach` command to dynamically concatenate a new slice, `/dev/dsk/c0t1d0s2`, to the end of an existing metadvice, `d8`. Next, the `growfs` command specifies that the mount-point is `/export` and that it is to be expanded onto the raw metadvice `/dev/md/rdisk/d8`. The file system will span the entire metadvice when `growfs` completes. During the expansion, write access for `/export` is suspended until `growfs` unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

### EXAMPLE 4 Expanding mounted file system to existing mirror

The following example expands a mounted file system `/files`, to an existing mirror, `d80`, which contains two submirrors, `d9` and `d10`.

```
metattach d9 c0t2d0s5
metattach d10 c0t3d0s5
growfs -M /files /dev/md/rdisk/d80
```

In this example, the `metattach` command dynamically concatenates the new slices to each submirror. The `metattach` command must be run for each submirror. The mirror will automatically grow when the last submirror is dynamically concatenated. The mirror will grow to the size of the smallest submirror. The `growfs` command then expands the file system. The `growfs` command specifies that the mount-point is

**EXAMPLE 4** Expanding mounted file system to existing mirror (Continued)

`/files` and that it is to be expanded onto the raw metadvice `/dev/md/rdisk/d80`. The file system will span the entire mirror when the `growfs` command completes. During the expansion, write access for the file system is suspended until `growfs` unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmdu         |

**SEE ALSO** `fsck(1M)`, `lockfs(1M)`, `mkfs(1M)`, `metattach(1M)`, `newfs(1M)`, `attributes(5)`

*Solaris Volume Manager Administration Guide*

**LIMITATIONS** Only UFS file systems (either mounted or unmounted) can be expanded using the `growfs` command. Once a file system is expanded, it cannot be decreased in size. The following conditions prevent you from expanding file systems: When `acct` is activated and the accounting file is on the target device. When C2 security is activated and the logging file is on the target file system. When there is a local swap file in the target file system. When the file system is `root (/)`, `/usr`, or `swap`.

| <b>DESCRIPTION</b>             | <p>The <code>gsscred</code> utility is used to create and maintain a mapping between a security principal name and a local UNIX <i>uid</i>. The format of the user name is assumed to be <code>GSS_C_NT_USER_NAME</code>. You can use the <code>-o</code> option to specify the object identifier of the <i>name</i> type. The OID must be specified in dot-separated notation, for example: <code>1.2.3.45464.3.1</code>.</p> <p>The <code>gsscred</code> table is used on server machines to lookup the <i>uid</i> of incoming clients connected using <code>RPCSEC_GSS</code>.</p> <p>When adding users, if no <i>user</i> name is specified, an entry is created in the table for each user from the <code>passwd</code> table. If no <i>comment</i> is specified, the <code>gsscred</code> utility inserts a comment that specifies the user name as an ASCII string and the GSS-API security mechanism that applies to it. The security mechanism will be in string representation as defined in the <code>/etc/gss/mech</code> file.</p> <p>The parameters are interpreted the same way by the <code>gsscred</code> utility to delete users as they are to create users. At least one of the following options must be specified: <code>-n</code>, <code>-u</code>, or <code>-m</code>. If no security mechanism is specified, then all entries will be deleted for the user identified by either the <i>uid</i> or <i>user</i> name. If only the security mechanism is specified, then all <i>user</i> entries for that security mechanism will be deleted.</p> <p>Again, the parameters are interpreted the same way by the <code>gsscred</code> utility to search for users as they are to create users. If no options are specified, then the entire table is returned. If the <i>user</i> name or <i>uid</i> is specified, then all entries for that <i>user</i> are returned. If a security mechanism is specified, then all <i>user</i> entries for that security mechanism are returned.</p> |                 |                    |                                |                                        |                 |                         |                             |                                                                |                             |                                      |                            |                                                       |                 |                                  |                            |                                                                             |

| <code>-u <i>uid</i></code>     | Specify the <i>uid</i> for the <i>user</i> if the <i>user</i> is not local.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                    |                                |                                        |                 |                         |                             |                                                                |                             |                                      |                            |                                                       |                 |                                  |                            |                                                                             |

**EXAMPLES****EXAMPLE 1** Creating a gsscred Table for the Kerberos v5 Security Mechanism

The following shows how to create a gsscred table for the kerberos v5 security mechanism. gsscred obtains *user* names and *uid*'s from the *passwd* table to populate the table.

```
example% gsscred -m kerberos_v5 -a
```

**EXAMPLE 2** Adding an Entry for root/host1 for the Kerberos v5 Security Mechanism

The following shows how to add an entry for root/host1 with a specified *uid* of 0 for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -n root/host1 -u 0 -a
```

**EXAMPLE 3** Listing All User Mappings for the Kerberos v5 Security Mechanism

The following lists all user mappings for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -l
```

**EXAMPLE 4** Listing All Mappings for All Security Mechanism for a Specified User

The following lists all mappings for all security mechanisms for the user bsimpson..

```
example% gsscred -n bsimpson -l
```

**EXIT STATUS**

The following exit values are returned:

```
0 Successful completion.
>0 An error occurred.
```

gssd(1M)

**NAME** gssd – generates and validates GSS-API tokens for kernel RPC

**SYNOPSIS** /usr/lib/gss/gssd

**DESCRIPTION** gssd is the user mode daemon that operates between the kernel rpc and the Generic Security Service Application Program Interface (GSS-API) to generate and validate GSS-API security tokens. In addition, gssd maps the GSS-API principal names to the local user and group ids. By default, all groups that the requested user belongs to will be included in the grouplist credential. gssd is invoked by the Internet daemon inetd(1m) the first time that the kernel RPC requests GSS-API services.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

| <b>SYNOPSIS</b>    | <code>/usr/sbin/halt [-dlngy]</code><br><code>/usr/sbin/poweroff [-dlngy]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>halt</code> and <code>poweroff</code> utilities write any pending information to the disks and then stop the processor. The <code>poweroff</code> utility will have the machine remove power, if possible.</p> <p>The <code>halt</code> and <code>poweroff</code> utilities normally log the system shutdown to the system log daemon, <code>syslogd(1M)</code>, and place a shutdown record in the login accounting file <code>/var/adm/wtmpx</code>. These actions are inhibited if the <code>-n</code> or <code>-q</code> options are present.</p>                                                 |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-d</code> Force a system crash dump before rebooting. See <code>dumpadm(1M)</code> for information on configuring system crash dumps.</li> <li><code>-l</code> Suppress sending a message to the system log daemon, <code>syslogd(1M)</code>, about who executed <code>halt</code>.</li> <li><code>-n</code> Prevent the <code>sync(1M)</code> before stopping.</li> <li><code>-q</code> Quick halt. No graceful shutdown is attempted.</li> <li><code>-y</code> Halt the system, even from a dialup terminal.</li> </ul> |                |                 |              |         |
| <b>FILES</b>       | <code>/var/adm/wtmpx</code> History of user access and administration information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |

| <b>NAME</b>        | hostconfig – configure a system’s host parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/hostconfig -p protocol [-d] [-h] [-n] [-v] [-i interface] [-f hostname]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The <code>hostconfig</code> program uses a network protocol to acquire a machine’s <i>host parameters</i> and set these parameters on the system.</p> <p>The program selects which protocol to use based on the argument to the required <code>-p</code> flag. Different protocols may set different host parameters. Currently, only one protocol (<code>bootparams</code>) is defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-d</code> Enable debug output.</li><li><code>-f hostname</code> Run the protocol as if this machine were named <code>hostname</code>.</li><li><code>-h</code> Echo the received <code>hostname</code> to <code>stdout</code>, rather than setting <code>hostname</code> using the system name directly.</li><li><code>-i interface</code> Use only the named network interface to run the protocol.</li><li><code>-n</code> Run the network protocol, but do not set the acquired parameters into the system.</li><li><code>-p protocol</code> Run <code>hostconfig</code> using <i>protocol</i>. Currently, only one protocol (<code>bootparams</code>) is available. This option is required.<br/><br/>Specifying the <code>-p bootparams</code> option uses the <code>whoami</code> call of the RPC <code>bootparams</code> protocol. This sets the system’s <code>hostname</code>, <code>domainname</code>, and default IP router parameters.</li><li><code>-v</code> Enable verbose output.</li></ul> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Configuring host parameters with verbose output</p> <p>The following command configures a machine’s host parameters using the <code>whoami</code> call of the RPC <code>bootparams</code> protocol with a verbose output.</p> <pre>example# hostconfig -p bootparams -v</pre> <p><b>EXAMPLE 2</b> Displaying host parameters</p> <p>The following command displays the parameters that would be set using the <code>whoami</code> call of the RPC <code>bootparams</code> protocol.</p> <pre>example# hostconfig -p bootparams -n -v</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**EXAMPLE 3** Configuring host parameters less the system name

The following command configures a machine's host parameters, less the system name, using the `whoami` call of the RPC `bootparams` protocol.

```
example# hostconfig='hostconfig -p bootparams -h '
```

| <b>SYNOPSIS</b>    | <code>/usr/sbin/htable filename</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |          |
| <b>DESCRIPTION</b> | <p>htable converts a host table in the format specified by RFC 952 to the format used by the network library routines. Three files are created as a result of running htable: <code>hosts</code>, <code>networks</code>, and <code>gateways</code>. The <code>hosts</code> file is used by the <code>gethostbyname(3NSL)</code> routines in mapping host names to addresses. The <code>networks</code> file is used by the <code>getnetbyname(3SOCKET)</code> routines in mapping network names to numbers. The <code>gateways</code> file is used by the routing daemon to identify “passive” Internet gateways.</p> <p>If any of the files <code>localhosts</code>, <code>localnetworks</code>, or <code>localgateways</code> are present in the current directory, the file’s contents is prepended to the output file without interpretation. This allows sites to maintain local aliases and entries which are not normally present in the master database.</p> <p>htable is best used in conjunction with the <code>gettable(1M)</code> program which retrieves the DoD Internet host table from a host.</p> |                |                 |              |          |
| <b>FILES</b>       | <code>localhosts</code><br><code>localnetworks</code><br><code>localgateways</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |          |

| <b>NAME</b>        | id – return user identity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre> /usr/bin/id [-p] [user] /usr/bin/id -a [-p] [user] /usr/xpg4/bin/id [-p] [user] /usr/xpg4/bin/id -G [-n] [user] /usr/xpg4/bin/id -g [-nr] [user] /usr/xpg4/bin/id -u [-nr] [user] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>If no <i>user</i> operand is provided, the <i>id</i> utility writes the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both are written. If multiple groups are supported by the underlying system, <i>/usr/xpg4/bin/id</i> also writes the supplementary group affiliations of the invoking process.</p> <p>If a <i>user</i> operand is provided and the process has the appropriate privileges, the user and group IDs of the selected user are written. In this case, effective IDs are assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, <i>/usr/xpg4/bin/id</i> writes them in the same manner as the supplementary groups described in the preceding paragraph.</p>                                                                                                                                                                                                                                       |
| <b>Formats</b>     | <p>The following formats are used when the <i>LC_MESSAGES</i> locale category specifies the "C" locale. In other locales, the strings <i>uid</i>, <i>gid</i>, <i>eid</i>, <i>egid</i>, and <i>groups</i> may be replaced with more appropriate strings corresponding to the locale.</p> <pre> "uid=%u(%s) gid=%u(%s)\n" &lt;real user ID&gt;, &lt;user-name&gt;, &lt;real group ID&gt;, &lt;group-name&gt; </pre> <p>If the effective and real user IDs do not match, the following are inserted immediately before the <code>\n</code> character in the previous format:</p> <pre> " eid=%u(%s) " </pre> <p>with the following arguments added at the end of the argument list:</p> <pre> &lt;effective user ID&gt;, &lt;effective user-name&gt; </pre> <p>If the effective and real group IDs do not match, the following is inserted directly before the <code>\n</code> character in the format string (and after any addition resulting from the effective and real user IDs not matching):</p> <pre> " egid=%u(%s) " </pre> <p>with the following arguments added at the end of the argument list:</p> |

id(1M)

*<effectivegroup-ID>, <effectivegroupname>*

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first is added directly before the NEWLINE character in the format string:

```
" groups=%u (%s) "
```

with the following arguments added at the end of the argument list:

*<supplementary group ID>, <supplementary group name>*

and the necessary number of the following added after that for any remaining supplementary group IDs:

```
", %u (%s) "
```

and the necessary number of the following arguments added at the end of the argument list:

*<supplementary group ID>, <supplementary group name>*

If any of the user ID, group ID, effective user ID, effective group ID or supplementary/multiple group IDs cannot be mapped by the system into printable user or group names, the corresponding (%s) and name argument is omitted from the corresponding format string.

When any of the options are specified, the output format is as described under OPTIONS.

#### OPTIONS

The following option is supported by both `/usr/bin/id` and `/usr/xpg4/bin/id`. For `/usr/xpg4/bin/id`, `-p` is invalid if specified with any of the `-G`, `-g`, or `-u` options.

`-p` Reports additionally the current project membership of the invoking process. The project is reported using the format:

```
"projid=%u (%s) "
```

which is inserted prior to the `\n` character of the default format described in the `Formats` section. The arguments

*<project ID>, <project name>*

are appended to the end of the argument list. If the project ID cannot be mapped by the system into a printable project name, the corresponding (%s) and name argument is omitted from the corresponding format string.

#### `/usr/bin/id`

The following option is supported for `/usr/bin/id` only:

|                              | -a                                                                                                                                                                                                                                                           | Reports user name, user ID and all the groups to which the user belongs.                                                                                                                                                                                                           |                |                 |              |          |  |         |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|----------|--|---------|
| <b>/usr/xpg4/bin/id</b>      | The following options are supported for <code>/usr/xpg4/bin/id</code> only:                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                    |                |                 |              |          |  |         |
|                              | -G                                                                                                                                                                                                                                                           | Output all different group IDs (effective, real and supplementary) only, using the format " <code>%u\n</code> ". If there is more than one distinct group affiliation, output each such affiliation, using the format " <code>%u</code> ", before the NEWLINE character is output. |                |                 |              |          |  |         |

| <b>NAME</b>                              | idsconfig – prepare an iPlanet Directory Server (iDS) to be populated with data and serve LDAP clients                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                         |                                                                                                                                                                                                                                                                                                                                                                                                                   |                                          |                                                        |                 |                 |
| <b>SYNOPSIS</b>                          | <code>/usr/lib/ldap/idsconfig [-v] [-i <i>input_configfile</i>] [-o <i>output_configfile</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                         |                                                                                                                                                                                                                                                                                                                                                                                                                   |                                          |                                                        |                 |                 |
| <b>DESCRIPTION</b>                       | <p>Use the <code>idsconfig</code> tool to set up an iPlanet Directory Server (iDS). You can specify the input configuration file with the <code>-i</code> option on the command line. Alternatively, the tool will prompt the user for configuration information. The input configuration file is created by <code>idsconfig</code> with the <code>-o</code> option on a previous run.</p> <p>The first time a server is set up, the user is prompted for all the required information. Future installations on that machine can use the configuration file previously generated by <code>idsconfig</code> using the <code>-o</code> option.</p> <p>The output configuration file contains the directory administrator's password in clear text. Thus, if you are creating an output configuration file, take appropriate security precautions.</p> <p>You should back up the directory server's configuration and data prior to running this command.</p> |                                         |                                                                                                                                                                                                                                                                                                                                                                                                                   |                                          |                                                        |                 |                 |
| <b>OPTIONS</b>                           | <table><tr><td><code>-i <i>input_configfile</i></code></td><td>Specify the file name for <code>idsconfig</code> to use as a configuration file. This file will be read by <code>idsconfig</code>, and the values in the file will be used to configure the server. Do not manually edit <i>input_configfile</i>. The <i>input_configfile</i> is only partially validated, as <code>idsconfig</code> assumes that the file was created by a previous invocation of the command.</td></tr><tr><td><code>-o <i>output_configfile</i></code></td><td>Create a configuration file.</td></tr><tr><td><code>-v</code></td><td>Verbose output.</td></tr></table>                                                                                                                                                                                                                                                                                                   | <code>-i <i>input_configfile</i></code> | Specify the file name for <code>idsconfig</code> to use as a configuration file. This file will be read by <code>idsconfig</code> , and the values in the file will be used to configure the server. Do not manually edit <i>input_configfile</i> . The <i>input_configfile</i> is only partially validated, as <code>idsconfig</code> assumes that the file was created by a previous invocation of the command. | <code>-o <i>output_configfile</i></code> | Create a configuration file.                           | <code>-v</code> | Verbose output. |
| <code>-i <i>input_configfile</i></code>  | Specify the file name for <code>idsconfig</code> to use as a configuration file. This file will be read by <code>idsconfig</code> , and the values in the file will be used to configure the server. Do not manually edit <i>input_configfile</i> . The <i>input_configfile</i> is only partially validated, as <code>idsconfig</code> assumes that the file was created by a previous invocation of the command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                         |                                                                                                                                                                                                                                                                                                                                                                                                                   |                                          |                                                        |                 |                 |
| <code>-o <i>output_configfile</i></code> | Create a configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                         |                                                                                                                                                                                                                                                                                                                                                                                                                   |                                          |                                                        |                 |                 |

**EXAMPLE 3** Setting up iDS Using the Specified Configuration File

In the following example, iDS is set up by using the values specified in the configuration file, `config.1`. The verbose mode is specified, so detailed information will print to the screen.

```
example# idsconfig -v -i config.1
```

**EXIT STATUS** The following exit values are returned:

```
0 Successful completion.
>0 An error occurred.
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWnisu        |
| Interface Stability | Evolving        |

| <b>DESCRIPTION</b> | <p>The command <code>ifconfig</code> is used to assign an address to a network interface and to configure network interface parameters. The <code>ifconfig</code> command must be used at boot time to define the network address of each interface present on a machine; it may also be used at a later time to redefine an interface's address or other operating parameters. If no option is specified, <code>ifconfig</code> displays the current configuration for a network interface. If an address family is specified, <code>ifconfig</code> reports only the details specific to that address family. Only the superuser may modify the configuration of a network interface. Options appearing within braces (<code>{ }</code>) indicate that one of the options must be specified.</p> <p>The two versions of <code>ifconfig</code>, <code>/sbin/ifconfig</code> and <code>/usr/sbin/ifconfig</code>, behave differently with respect to name services. The order in which names are looked</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

up by `/sbin/ifconfig` when the system is booting is fixed and cannot be changed. In contrast, changing `/etc/nsswitch.conf` may affect the behavior of `/usr/sbin/ifconfig`. The system administrator may configure the source and lookup order in the tables by means of the name service switch. See `nsswitch.conf(4)` for more information.

### DHCP Configuration

The third and fourth forms of this command are used to control the Dynamic Host Configuration Protocol (“DHCP”) configuring of the interface. DHCP is only available on interfaces for which the address family is `inet`. In this mode, `ifconfig` is used to control operation of `dhcpgent(1M)`, the DHCP client daemon. Once an interface is placed under DHCP control by using the `start` operand, `ifconfig` should not, in normal operation, be used to modify the address or characteristics of the interface. If the address of an interface under DHCP is changed, `dhcpgent` will remove the interface from its control.

### OPTIONS

The following options are supported:

`addif address`

Create the next unused logical interface on the specified physical interface.

`arp`

Enable the use of the Address Resolution Protocol (“ARP”) in mapping between network level addresses and link level addresses (default). This is currently implemented for mapping between IPv4 addresses and 10Mb/s Ethernet addresses.

`-arp`

Disable the use of the ARP.

`auth_algs authentication algorithm`

For a tunnel, enable IPsec AH with the authentication algorithm specified. The algorithm can be either a number or an algorithm name, including *any* to express no preference in algorithm. All IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify an `auth_alg` of *none*.

`auto-dhcp`

Use DHCP to automatically acquire an address for this interface. This option has a completely equivalent alias called `dhcp`.

`primary`

Defines the interface as the `primary`. The interface is defined as the preferred one for the delivery of client-wide configuration data. Only one interface can be the primary at any given time. If another interface is subsequently selected as the primary, it replaces the previous one. Nominating an interface as the primary one will not have much significance once the client work station has booted, as many applications will already have started and been configured with data read from the previous primary interface.

## ifconfig(1M)

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>wait <i>seconds</i></code>      | The <code>ifconfig</code> command will wait until the operation either completes or for the interval specified, whichever is the sooner. If no wait interval is given, and the operation is one that cannot complete immediately, <code>ifconfig</code> will wait 30 seconds for the requested operation to complete. The symbolic value <code>forever</code> may be used as well, with obvious meaning.                                                                 |
| <code>drop</code>                     | Remove the specified interface from DHCP control. Additionally, set the IP address to zero and mark the interface as "down".                                                                                                                                                                                                                                                                                                                                             |
| <code>extend</code>                   | Attempt to extend the lease on the interface's IPv4 address. This is not required, as the agent will automatically extend the lease well before it expires.                                                                                                                                                                                                                                                                                                              |
| <code>inform</code>                   | Obtain network configuration parameters from DHCP without obtaining a lease on an IP address. This is useful in situations where an IP address is obtained through mechanisms other than DHCP.                                                                                                                                                                                                                                                                           |
| <code>ping</code>                     | Check whether the interface given is under DHCP control, which means that the interface is managed by the DHCP agent and is working properly. An exit status of 0 means success. This subcommand has no meaning when the named interface represents more than one interface.                                                                                                                                                                                             |
| <code>release</code>                  | Relinquish the IPv4 address on the interface, and mark the interface as "down."                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>start</code>                    | Start DHCP on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>status</code>                   | Display the DHCP configuration status of the interface.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>auto-revarp</code>              | Use the Reverse Address Resolution Protocol ("RARP") to automatically acquire an address for this interface.                                                                                                                                                                                                                                                                                                                                                             |
| <code>broadcast <i>address</i></code> | For IPv4 only. Specify the address to use to represent broadcasts to the network. The default broadcast address is the address with a host part of all 1's. A "+" (plus sign) given for the broadcast value causes the broadcast address to be reset to a default appropriate for the (possibly new) address and netmask. The arguments of <code>ifconfig</code> are interpreted left to right. Therefore<br><br><code>example% ifconfig -a netmask + broadcast +</code> |
| <code>and</code>                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

```
example% ifconfig -a broadcast + netmask +
```

may result in different values being assigned for the broadcast addresses of the interfaces.

#### deprecated

Marks the address as a deprecated address. Addresses marked as deprecated will not be used as source address for outbound packets unless either there are no other addresses available on this interface or the application has bound to this address explicitly. The status display shows DEPRECATED as part of flags.

#### -deprecated

Marks the address as not deprecated.

#### destination *dest\_address*

Set the destination address for a point-to point interface.

#### dhcp

This option is an alias for option `auto-dhcp`.

#### down

Mark an interface "down". When an interface is marked "down", the system does not attempt to transmit messages through that interface. If possible, the interface is reset to disable reception as well. This action does not automatically disable routes using the interface.

#### encr\_auth\_algs *authentication algorithm*

For a tunnel, enable IPsec ESP with the authentication algorithm specified. It can be either a number or an algorithm name, including any or none, to indicate no algorithm preference. If an ESP encryption algorithm is specified but the authentication algorithm is not, the default value for the ESP authentication algorithm will be any.

#### encr\_algs *encryption algorithm*

For a tunnel, enable IPsec ESP with the encryption algorithm specified. It can be either a number or an algorithm name. Note that all IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify the value of `encr_alg` as none. If an ESP authentication algorithm is specified, but the encryption algorithm is not, the default value for the ESP encryption will be null.

#### -failover

Mark the address as a non-failover address. Addresses marked this way will not failover when the interface fails. Status display shows "NOFAILOVER" as part of flags.

#### failover

Mark the address as a failover address. This address will failover when the interface fails. Status display does not show "NOFAILOVER" as part of flags.

## ifconfig(1M)

`group [ name | "" ]`

Insert the interface in the multipathing group specified by *name*. To delete an interface from a group, use a null string "". When invoked on the logical interface with id zero, the status display shows the group name.

`index n`

Change the interface index for the interface. The value of *n* must be an interface index (*if\_index*) that is not used on another interface. *if\_index* will be a non-zero positive number that uniquely identifies the network interface on the system.

`metric n`

Set the routing metric of the interface to *n*; if no value is specified, the default is 0. The routing metric is used by the routing protocol. Higher metrics have the effect of making a route less favorable; metrics are counted as addition hops to the destination network or host.

`modinsert mod_name@pos`

Insert a module with name *mod\_name* to the stream of the device at position *pos*. The position is relative to the stream head. Position 0 means directly under stream head.

Based upon the example in the `modlist` option, use the following command to insert a module with name `ipqos` under the `ip` module and above the firewall module:

```
example% ifconfig hme0 modinsert ipqos@2
```

A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig hme0 modlist
0 arp
1 ip
2 ipqos
3 firewall
4 hme
```

`modlist`

List all the modules in the stream of the device.

The following example lists all the modules in the stream of the device:

```
example% ifconfig hme0 modlist
0 arp
1 ip
2 firewall
4 hme
```

`modremove mod_name@pos`

Remove a module with name *mod\_name* from the stream of the device at position *pos*. The position is relative to the stream head.

Based upon the example in the `modinsert` option, use the following command to remove the firewall module from the stream after inserting the `ipqos` module:

```
example% ifconfig hme0 modremove firewall@3
```

A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig hme0 modlist
0 arp
1 ip
2 ipqos
3 hme
```

Note that the core IP stack modules, for example, `ip` and `tun` modules, cannot be removed.

#### `mtu n`

Set the maximum transmission unit of the interface to *n*. For many types of networks, the `mtu` has an upper limit, for example, 1500 for Ethernet.

#### `netmask mask`

For IPv4 only. Specify how much of the address to reserve for subdividing networks into subnetworks. The mask includes the network part of the local address and the subnet part, which is taken from the host field of the address. The mask contains 1's for the bit positions in the 32-bit address which are to be used for the network and subnet parts, and 0's for the host part. The mask should contain at least the standard network portion, and the subnet field should be contiguous with the network portion. The mask can be specified in one of four ways:

1. with a single hexadecimal number with a leading 0x,
2. with a dot-notation address,
3. with a "+" (plus sign) address, or
4. with a pseudo host name/pseudo network name found in the network database `networks(4)`.

If a "+" (plus sign) is given for the netmask value, the mask is looked up in the `netmasks(4)` database. This lookup finds the longest matching netmask in the database by starting with the interface's IPv4 address as the key and iteratively masking off more and more low order bits of the address. This iterative lookup ensures that the `netmasks(4)` database can be used to specify the netmasks when variable length subnetmasks are used within a network number.

If a pseudo host name/pseudo network name is supplied as the netmask value, netmask data may be located in the `hosts` or `networks` database. Names are looked up by first using `gethostbyname(3NSL)`. If not found there, the names are looked up in `getnetbyname(3SOCKET)`. These interfaces may in turn use `nsswitch.conf(4)` to determine what data store(s) to use to fetch the actual value.

For both `inet` and `inet6`, the same information conveyed by *mask* can be specified as a *prefix\_length* attached to the *address* parameter.

## ifconfig(1M)

**nud**  
Enables the neighbor unreachability detection mechanism on a point-to-go interface.

**-nud**  
Disables the neighbor unreachability detection mechanism on a point-to-go interface.

**plumb**  
Open the device associated with the physical interface name and set up the streams needed for IP to use the device. When used with a logical interface name, this command is used to create a specific named logical interface. An interface must be separately plumbed for use by IPv4 and IPv6. The *address\_family* parameter controls whether the `ifconfig` command applies to IPv4 or IPv6.

Before an interface has been plumbed, , the interface will not show up in the output of the `ifconfig -a` command.

**private**  
Tells the `in.routed` routing daemon that the interface should not be advertised.

**-private**  
Specify unadvertised interfaces.

**removeif *address***  
Remove the logical interface on the physical interface specified that matches the *address* specified.

**set**  
Set the *address*, *prefix\_length* or both, for an interface.

**standby**  
Marks the physical interface as a standby interface. If the interface is marked STANDBY and is part of the multipathing group, the interface will not be selected to send out packets unless some other interface in the group has failed and the network access has been failed over to this standby interface.

The status display shows "STANDBY, INACTIVE" indicating that that the interface is a standby and is also inactive. `IFF_INACTIVE` will be cleared when some other interface belonging to the same multipathing group fails over to this interface. Once a failback happens, the status display will return to `INACTIVE`.

**-standby**  
Turns off standby on this interface.

**subnet**  
Set the subnet *address* for an interface.

**tdst *tunnel\_dest\_address***  
Set the destination address of a tunnel. The address should not be the same as the `dest_address` of the tunnel, because no packets leave the system over such a tunnel.

**trailers**

This flag previously caused a nonstandard encapsulation of `inet` packets on certain link levels. Drivers supplied with this release no longer use this flag. It is provided for compatibility, but is ignored.

**-trailers**

Disable the use of a "trailer" link level encapsulation.

**tsrc *tunnel\_src\_address***

Set the source address of a tunnel. This is the source address on an outer encapsulating IP header. It must be an address of another interface already configured using `ifconfig`.

**unplumb**

Close the device associated with this physical interface name and any streams that `ifconfig` set up for IP to use the device. When used with a logical interface name, the logical interface is removed from the system. After this command is executed, the device name will no longer appear in the output of `ifconfig -a`.

**up**

Mark an interface "up". This happens automatically when setting the first address on an interface. The `up` option enables an interface after an `ifconfig down`, which reinitializes the hardware.

**xmit**

Enable an interface to transmit packets. This is the default behavior when the interface is up.

**-xmit**

Disable transmission of packets on an interface. The interface will continue to receive packets.

**OPERANDS** The *interface* operand, as well as address parameters that affect it, are described below.

***interface***

A string of the form, *name physical-unit*, for example, `le0` or `ie1`; or of the form *name physical-unit : logical-unit*, for example, `le0 : 1`; or of the form `ip.tunN`, for tunnels.

If the interface name starts with a dash (-), it is interpreted as a set of options which specify a set of interfaces. In such a case, `-a` must be part of the options and any of the additional options below can be added in any order. If one of these interface names is given, the commands following it are applied to all of the interfaces that match.

- `-a` Apply the commands to all interfaces in the system.
- `-d` Apply the commands to all "down" interfaces in the system.

## ifconfig(1M)

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <i>address_family</i> | <p>The address family is specified by the <i>address_family</i> parameter. The <code>ifconfig</code> command currently supports the following families: <code>ether</code>, <code>inet</code>, and <code>inet6</code>. If no address family is specified, the default is <code>inet</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>address</i>        | <p>For the IPv4 family (<code>inet</code>), the <i>address</i> is either a host name present in the host name data base (see <code>hosts(4)</code>) or in the Network Information Service (NIS) map <code>hosts</code>, or an IPv4 address expressed in the Internet standard "dot notation".</p> <p>For the IPv6 family (<code>inet6</code>), the <i>address</i> is either a host name present in the host name data base (see <code>ipnodes(4)</code>) or in the Network Information Service (NIS) map <code>ipnode</code>, or an IPv6 address expressed in the Internet standard colon-separated hexadecimal format represented as <code>x::x::x::x::x::x</code> where <code>x</code> is a hexadecimal number between 0 and <code>FFFF</code>.</p> <p>For the <code>ether</code> address family, the address is an Ethernet address represented as <code>x:x:x: x:x:x</code> where <code>x</code> is a hexadecimal number between 0 and <code>FF</code>.</p> <p>Some, though not all, of the Ethernet interface cards have their own addresses. To use cards that do not have their own addresses, refer to section 3.2.3(4) of the IEEE 802.3 specification for a definition of the locally administered address space. The use of interface groups should be restricted to those cards with their own addresses (see <code>INTERFACE GROUPS</code>).</p> |
| <i>prefix_length</i>  | <p>For the IPv4 and IPv6 families (<code>inet</code> and <code>inet6</code>), the <i>prefix_length</i> is a number between 0 and the number of bits in the address. For <code>inet</code>, the number of bits in the address is 32; for <code>inet6</code>, the number of bits in the address is 128. The <i>prefix_length</i> denotes the number of leading set bits in the netmask.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                            |                                                                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dest_address</i>        | If the <i>dest_address</i> parameter is supplied in addition to the <i>address</i> parameter, it specifies the address of the correspondent on the other end of a point-to-point link.                                                               |
| <i>tunnel_dest_address</i> | An address that is or will be reachable through an interface other than the tunnel being configured. This tells the tunnel where to send the tunneled packets. This address must not be the same as the <i>tunnel_dest_address</i> being configured. |
| <i>tunnel_src_address</i>  | As address that is attached to an already configured interface that has been configured "up" with <code>ifconfig</code> .                                                                                                                            |

## LOGICAL INTERFACES

Solaris TCP/IP allows multiple logical interfaces to be associated with a physical network interface. This allows a single machine to be assigned multiple IP addresses, even though it may have only one network interface. Physical network interfaces have names of the form *driver-name physical-unit-number*, while logical interfaces have names of the form *driver-name physical-unit-number : logical-unit-number*. A physical interface is configured into the system using the `plumb` command. For example:

```
example% ifconfig le0 plumb
```

Once a physical interface has been "plumbed", logical interfaces associated with the physical interface can be configured by separate `plumb` or `addif` options to the `ifconfig` command.

```
example% ifconfig le0:1 plumb
```

allocates a specific logical interface associated with the physical interface `le0`. The command

```
example% ifconfig le0 addif 192.9.200.1/24 up
```

allocates the next available logical unit number on the `le0` physical interface and assigns an *address* and *prefix\_length*.

A logical interface can be configured with parameters (*address*, *prefix\_length*, and so on) different from the physical interface with which it is associated. Logical interfaces that are associated with the same physical interface can be given different parameters as well. Each logical interface must be associated with an existing and "up" physical interface. So, for example, the logical interface `le0:1` can only be configured after the physical interface `le0` has been plumbed.

To delete a logical interface, use the `unplumb` or `removeif` options. For example,

```
example% ifconfig le0:1 down unplumb
```

ifconfig(1M)

## INTERFACE GROUPS

will delete the logical interface `le0:1`.

If a physical interface shares an IP prefix with another interface, these interfaces are collected into an interface group. IP uses an interface group to rotate source address selection when the source address is unspecified, and in the case of multiple physical interfaces in the same group, to scatter traffic across different IP addresses on a per-IP-destination basis. See `netstat(1M)` for per-IP-destination information.

This feature may be enabled by using `ndd(1M)`.

One can also use the `group` keyword to form a multipathing group. When multipathing groups are used, the functionality of the `interface group` is subsumed into the functionality of the multipathing group. A multipathing group provides failure detection and repair detection for the interfaces in the group. See `in.mpathd(1M)` and *System Administration Guide, Volume 3*.

The interface groups formed using `ndd(1M)` will be made obsolete in the future. Accordingly, it is advisable to use form multipathing groups using the `group` keyword.

## CONFIGURING IPv6 INTERFACES

When an IPv6 physical interface is plumbed and configured “up” with `ifconfig`, it is automatically assigned an IPv6 link-local address for which the last 64 bits are calculated from the MAC address of the interface.

```
ifconfig le0 inet6 plumb up
```

The following example shows that the link-local address has a prefix of `fe80::/10`.

```
example% ifconfig le0 inet6
le0: flags=2000841<UP, RUNNING, MULTICAST, IPv6>
 mtu 1500 index 2
 inet6 fe80::a00:20ff:fe8e:f3ad/10
```

If an advertising IPv6 router exists on the link advertising prefixes, then the newly plumbed IPv6 interface will autoconfigure logical interface(s) depending on the prefix advertisements. For example, for prefix advertisements `fec0:0:0:55::/64` and `3ff0:0:0:55::/64`, the autoconfigured interfaces will look like:

```
le0:1: flags=2080841<UP, RUNNING, MULTICAST, ADDRCONF, IPv6>
 mtu 1500 index 2
 inet6 fec0::55:a00:20ff:fe8e:f3ad/64
le0:2: flags=2080841<UP, RUNNING, MULTICAST, ADDRCONF, IPv6>
 mtu 1500 index 2
 inet6 3ff0::55:a00:20ff:fe8e:f3ad/64
```

Even if there are no prefix advertisements on the link, you can still assign site-local and global addresses manually, for example:

```
example% ifconfig le0 inet6 addif fec0::55:a00:20ff:fe8e:f3ad/64 up
example% ifconfig le0 inet6 addif 3ff0::55:a00:20ff:fe8e:f3ad/64 up
```

To configure boot-time defaults for the interface `le0`, place the following entries in the `/etc/hostname6.le0` file:

```
addif fec0::55:a0:20ff:fe8e:f3ad/64 up
addif 3ff0::55:a0:20ff:fe8e:f3ad/64 up
```

Link-local addresses are only used for on-link communication and are not visible to other subnets.

## Configuring IPv6/IPv4 tunnels

An IPv6 over IPv4 tunnel interface can send and receive IPv6 packets encapsulated in an IPv4 packet. Create tunnels at both ends pointing to each other. IPv6 over IPv4 tunnels require the tunnel source and tunnel destination IPv4 and IPv6 addresses. Solaris 8 supports both automatic and configured tunnels. For automatic tunnels, an IPv4-compatible IPv6 address is used. The following demonstrates auto-tunnel configuration:

```
example% ifconfig ip.atun0 inet6 plumb
example% ifconfig ip.atun0 inet6 tsrc <IPv4-address> \
 ::<IPv4 address>/96 up
```

where `IPv4-address` is the IPv4 address of the interface through which the tunnel traffic will flow, and `IPv4-address, ::<IPv4-address>`, is the corresponding IPv4-compatible IPv6 address.

The following is an example of a configured tunnel:

```
example% ifconfig ip.tun0 inet6 plumb tsrc <my-ipv4-address> \
 tdst <peer-ipv4-address> up
```

This creates a configured tunnel between `my-ipv4-address` and `peer-ipv4-address` with corresponding link-local addresses. For tunnels with global or site-local addresses, the logical tunnel interfaces need to be configured in the following form:

```
ifconfig ip.tun0 inet6 addif <my-v6-address> <peer-v6-address> up
```

For example,

```
example% ifconfig ip.tun0 inet6 plumb tsrc 109.146.85.57 \
 tdst 109.146.85.212 up
example% ifconfig ip.tun0 inet6 addif 2::45 2::46 up
```

To show all IPv6 interfaces that are up and configured:

```
example% ifconfig -au6
ip.tun0: flags=2200851<UP,POINTOPOINT,RUNNING,MULTICAST,NUD,IPv6>
 mtu 1480 index 3
 inet tunnel src 109.146.85.57 tunnel dst 109.146.85.212
 inet6 fe80::6d92:5539/10 --> fe80::6d92:55d4
```

## ifconfig(1M)

```
ip.tun0:1: flags=2200851<UP,POINTOPOINT,RUNNING,MULTICAST,NUD,IPv6>
 mtu 1480 index 3
 inet6 2::45/128 --> 2::46
```

### EXAMPLES

#### EXAMPLE 1 Using the ifconfig Command

If your workstation is not attached to an Ethernet, the `le0` interface should be marked "down" as follows:

```
example% ifconfig le0 down
```

#### EXAMPLE 2 Printing Addressing Information

To print out the addressing information for each interface, use the following command:

```
example% ifconfig -a
```

#### EXAMPLE 3 Resetting the Broadcast Address

To reset each interface's broadcast address after the netmasks have been correctly set, use the next command:

```
example% ifconfig -a broadcast +
```

#### EXAMPLE 4 Changing the Ethernet Address

To change the Ethernet address for interface `le0`, use the following command:

```
example% ifconfig le0 ether aa:1:2:3:4:5
```

#### EXAMPLE 5 Configuring an IP-in-IP Tunnel

To configure an IP-in-IP tunnel, first plumb it with the following command:

```
example% ifconfig ip.tun0 plumb
```

Then configure it as a point-to-point interface, supplying the tunnel source and the tunnel destination:

```
example% ifconfig ip.tun0 myaddr mydestaddr tsrc another_myaddr \
 tdst a_dest_addr up
```

Tunnel security properties must be configured on one invocation of `ifconfig`:

```
example% ifconfig ip.tun0 encr_auth_algs md5 encr_algs 3des
```

**EXAMPLE 6** Requesting a Service Without Algorithm Preference

To request a service without any algorithm preferences, specify any:

```
example% ifconfig ip.tun0 encr_auth_algs any encr_algs any
```

**EXAMPLE 7** Disabling All Security

To disable all security, specify any security service with none as the algorithm value:

```
example% ifconfig ip.tun0 auth_algs none
```

or

```
example% ifconfig ip.tun0 encr_algs none
```

*System Administration Guide, Volume 3*

**DIAGNOSTICS** `ifconfig` sends messages that indicate if:

- the specified interface does not exist
- the requested address is unknown
- the user is not privileged and tried to alter an interface's configuration

## ifconfig(1M)

**NOTES** | It is recommended that the names `broadcast`, `down`, `private`, `trailers`, `up`, and the other possible option names not be selected when choosing host names. Choosing any one of these names as host names will cause bizarre problems that can be extremely difficult to diagnose.

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                |                                                                       |                                |                                                                                                                                                                                                                         |

| <b>NAME</b>                    | if_mpadm – change operational status of interfaces within a multipathing group                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>                | <pre>/usr/sbin/if_mpadm -d interface_name /usr/sbin/if_mpadm -r interface_name</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>             | <p>Use the <code>if_mpadm</code> utility to change the operational status of interfaces that are part of a multipathing group. If the interface is operational, you can use <code>if_mpadm -d</code> to detach or off-line the interface. If the interface is off-lined, use <code>if_mpadm -r</code> to revert it to its original state.</p> <p>When a network interface is off-lined, all network access fails over to a different interface in the multipathing group. Any addresses that do not failover are brought down. Network access includes unicast, broadcast, and multicast for IPv4 and unicast and multicast for IPv6. Addresses marked with <code>IFF_NOFAILOVER</code> do not failover; they are marked down. After an interface is off-lined, the system will not use the interface for any outbound or inbound traffic, and the interface can be safely removed from the system without any loss of network access.</p> <p>The <code>if_mpadm</code> utility can be applied only to interfaces that are part of a multipathing group.</p> |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <b>OPTIONS</b>                 | <p>The <code>if_mpadm</code> utility supports the following options:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>-d interface_name</code></td> <td>Detach or off-line the interface specified by <i>interface_name</i>.</td> </tr> <tr> <td><code>-r interface_name</code></td> <td>Reattach or undo the previous detach or off-line operation on the interface specified by <i>interface_name</i>. Unless the <code>-d</code> option was used to detach or off-line the interface, this option will fail.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <code>-d interface_name</code> | Detach or off-line the interface specified by <i>interface_name</i> . | <code>-r interface_name</code> | Reattach or undo the previous detach or off-line operation on the interface specified by <i>interface_name</i> . Unless the <code>-d</code> option was used to detach or off-line the interface, this option will fail. |
| <code>-d interface_name</code> | Detach or off-line the interface specified by <i>interface_name</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <code>-r interface_name</code> | Reattach or undo the previous detach or off-line operation on the interface specified by <i>interface_name</i> . Unless the <code>-d</code> option was used to detach or off-line the interface, this option will fail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <b>EXAMPLES</b>                | <p><b>EXAMPLE 1</b> Detaching an Interface</p> <p>Use the following command to off-line or detach the interface. All network access will failback to <code>hme0</code> from another interface in the group.</p> <pre>example% if_mpadm -d hme0</pre> <p><b>EXAMPLE 2</b> Reattaching an Off-line Interface</p> <p>Use the following command to undo the previous operation. Network access will failback over to <code>hme0</code> from an interface in the same multipathing group.</p> <pre>example% if_mpdadm -r hme0</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                |                                                                       |                                |                                                                                                                                                                                                                         |

**SEE ALSO** ifconfig(1M), in.mpathd(1M), attributes(5)

**DIAGNOSTICS** off-line failed as there is no other functional interface available in the multipathing group for failing over the network access.  
This message means that other interfaces in the group are failed over already or the multipathing configuration was not suitable for completing a failover.

off-line cannot be undone as failback has been disabled.  
FAILBACK is set to "no" in /etc/default/mpathd.

off-line cannot be undone because multipathing configuration is not consistent across all the interfaces in the group.  
This message means that some interfaces in the multipathing group are not configured consistently with other interfaces in the group, for example, one of the interfaces in the group does not have an IFF\_NOFAILOVER address.

| <b>DESCRIPTION</b> | Use the ifparse command to parse the ifconfig(1M) command line options and output substrings, one per line, as appropriate. If no options are specified, ifparse returns the entire ifconfig command line as a series of substrings, one per line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | The ifparse command supports the following options: <ul style="list-style-type: none"> <li>-f        Lists only substrings of the ifconfig command line that are relevant to IP network multipath failover</li> <li>-s        Lists only substrings of the ifconfig command line that are not relevant to IP network multipath failover</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPERANDS</b>    | The ifparse command <i>does not</i> support the <i>interface</i> operand of the ifconfig command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Parsing Command Line Options Relevant to Failover</p> <p>The following example shows the use of the ifparse command to parse the command line options relevant to IP network multipath failover:</p> <pre>example# ifparse -f inet 1.2.3.4 up group one addif 1.2.3.5 -failover up set 1.2.3.4 up</pre> <p><b>EXAMPLE 2</b> Parsing Command Line Options That Are Not Relevant to Failover</p> <p>The following example shows the use of the ifparse command to parse the command line options that are not relevant to IP network multipath failover:</p> <pre>example# ifparse -s inet 1.2.3.4 up group one addif 1.2.3.5 -failover up group one addif 1.2.3.5 -failover up</pre> <p><b>EXAMPLE 3</b> Parsing the Command Line For All Options</p> <p>The following example shows the use of the ifparse command to parse the command line for all ifconfig options:</p> <pre>example# ifparse inet 1.2.3.4 up group one addif 1.2.3.5 -failover up group one set 1.2.3.4 up addif 1.2.3.5 -failover up</pre> |
| <b>ATTRIBUTES</b>  | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## ifparse(1M)

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsr         |
| Stability Level | Obsolete        |

**SEE ALSO** ifconfig(1M), attributes(5)

**DIAGNOSTICS** usage: -fs <addr\_family> <commands>  
This message indicates an invalid command line.

ifparse: Not enough space  
This message indicates insufficient memory.

ifparse: dhcp not supported for inet6  
DHCP operations are not supported for the inet6 address family.

ifparse: Operation <operation> not supported for <addr\_family>  
Most operations cannot be used with all address families. For example, the broadcast operation is not supported on the inet6 address family.

ifparse: no argument for <operation>  
Some operations, for example broadcast, require an argument.

**NOTES** The ifparse command is classified as an obsolete interface. It will likely be removed in a future release. You should not develop applications that depend upon this interface.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>DESCRIPTION</b> | <p>The <code>ikeadm</code> utility retrieves information from and manipulates the configuration of the Internet Key Exchange (IKE) protocol daemon, in <code>.iked(1M)</code>.</p> <p><code>ikeadm</code> supports a set of operations, which may be performed on one or more of the supported object types. When invoked without arguments, <code>ikeadm</code> enters interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached.</p> <p>Because <code>ikeadm</code> manipulates sensitive keying information, you must be superuser to use this command. Additionally, some of the commands available require that the daemon be running in a privileged mode, which is established when the daemon is started.</p> <p>For details on how to use this command securely see <code>SECURITY</code>.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-n            Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.</li> <li>-p            Paranoid. Do not print any keying material, even if saving Security Associations. Instead of an actual hexadecimal digit, print an X when this flag is turned on.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Commands</b>    | <p>The following commands are supported:</p> <ul style="list-style-type: none"> <li>add            Add the specified object. This option can be used to add a new policy rule or a new preshared key to the current (running) <code>in.iked</code> configuration. When adding a new preshared key, the command cannot be invoked from the command line, as it will contain keying material. The rule or key being added is specified using appropriate id-value pairs as described in the <code>ID FORMATS</code> section.</li> </ul>                                                                                                                                                                                                                                                                                                                                                     |

|       |                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| del   | Delete a specific object from <code>in.iked</code> 's current configuration. This operation is available for IKE (Phase 1) SAs, policy rules, and preshared keys. The object to be deleted is specified as described in the <code>ID FORMATS</code> .                                                                                                                                                     |
| dump  | Display all objects of the specified type known to <code>in.iked</code> . This option can be used to display all Phase 1 SAs, policy rules, or preshared keys. A large amount of output may be generated by this command.                                                                                                                                                                                 |
| flush | Remove all IKE (Phase 1) SAs from <code>in.iked</code> .                                                                                                                                                                                                                                                                                                                                                  |
| get   | Lookup and display the specified object. May be used to view the current debug or privilege level, global statistics for the daemon, or a specific IKE (Phase 1) SA, policy rule, or preshared key. The latter three object types require that identifying information be passed in; the appropriate specification for each object type is described below.                                               |
| help  | Print a brief summary of commands, or, when followed by a command, prints information about that command.                                                                                                                                                                                                                                                                                                 |
| read  | Update the current <code>in.iked</code> configuration by reading the policy rules or preshared keys from either the default location or from the file specified.                                                                                                                                                                                                                                          |
| set   | Adjust the current debug or privilege level. If the debug level is being modified, an output file may optionally be specified; the output file <i>must</i> be specified if the daemon is running in the background and is not currently printing to a file. When changing the privilege level, adjustments may only be made to lower the access level; it cannot be increased using <code>ikeadm</code> . |
| write | Write the current <code>in.iked</code> policy rule set or preshared key set to the specified file. A destination file must be specified. This command should not be used to overwrite the existing configuration files.                                                                                                                                                                                   |

**OBJECT TYPES**

debug Specifies the daemon's debug level. This determines the amount and type of output provided by the daemon about its operations. The debug level is actually a bitmask, with individual bits enabling different types of information.

| Description            | Flag   | Nickname |
|------------------------|--------|----------|
| Certificate management | 0x0001 | cert     |
| Key management         | 0x0002 | key      |
| Operational            | 0x0004 | op       |

| Description            | Flag   | Nickname |
|------------------------|--------|----------|
| Phase 1 SA creation    | 0x0008 | phase1   |
| Phase 2 SA creation    | 0x0010 | phase2   |
| PF_KEY interface       | 0x0020 | pfkey    |
| Policy management      | 0x0040 | policy   |
| Proposal construction  | 0x0080 | prop     |
| Door interface         | 0x0100 | door     |
| Config file processing | 0x0200 | config   |
| All debug flags        | 0x3ff  | all      |

When specifying the debug level, either a number (decimal or hexadecimal) or a string of nicknames may be given. For example, 88, 0x58, and phase1+phase2+policy are all equivalent, and will turn on debug for phase 1 sa creation, phase 2 sa creation, and policy management. A string of nicknames may also be used to remove certain types of information; all-op has the effect of turning on all debug *except* for operational messages; it is equivalent to the numbers 1019 or 0x3fb.

priv

Specifies the daemon's access privilege level. The possible values are:

| Description                  | Level | Nickname |
|------------------------------|-------|----------|
| Base level                   | 0     | base     |
| Access to preshared key info | 1     | modkeys  |
| Access to keying material    | 2     | keymat   |

By default, `in.iked` is started at the base level. A command-line option can be used to start the daemon at a higher level. `ikeadm` can be used to lower the level, but it cannot be used to raise the level.

Either the numerical level or the nickname may be used to specify the target privilege level.

In order to get, add, delete, dump, read, or write preshared keys, the privilege level must at least give access to preshared key information. However, when viewing preshared keys (either using

## ikeadm(1M)

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <p>the <code>get</code> or <code>dump</code> command), the key itself will only be available if the privilege level gives access to keying material. This is also the case when viewing Phase 1 SAs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>stats</code>    | <p>Global statistics from the daemon, covering both successful and failed Phase 1 SA creation.</p> <p>Reported statistics include:</p> <ul style="list-style-type: none"><li>■ Count of current P1 SAs which the local entity initiated</li><li>■ Count of current P1 SAs where the local entity was the responder</li><li>■ Count of all P1 SAs which the local entity initiated since boot</li><li>■ Count of all P1 SAs where the local entity was the responder since boot</li><li>■ Count of all attempted P1 SAs since boot, where the local entity was the initiator; includes failed attempts</li><li>■ Count of all attempted P1 SAs since boot, where the local entity was the responder; includes failed attempts</li><li>■ Count of all failed attempts to initiate a P1 SA, where the failure occurred because the peer did not respond</li><li>■ Count of all failed attempts to initiate a P1 SA, where the peer responded</li><li>■ Count of all failed P1 SAs where the peer was the initiator</li></ul> |
| <code>p1</code>       | <p>An IKE Phase 1 SA. A <code>p1</code> object is identified by an IP address pair or a cookie pair; identification formats are described below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>rule</code>     | <p>An IKE policy rule, defining the acceptable security characteristics for Phase 1 SAs between specified local and remote identities. A rule is identified by its label; identification formats are described below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>prshared</code> | <p>A preshared key, including the local and remote identification and applicable IKE mode. A preshared key is identified by an IP address pair or an identity pair; identification formats are described below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### ID FORMATS

Commands like `add`, `del`, and `get` require that additional information be specified on the command line. In the case of the delete and get commands, all that is required is to minimally identify a given object; for the add command, the full object must be specified.

Minimal identification is accomplished in most cases by a pair of values. For IP addresses, the local `addr` and then the remote `addr` are specified, either in dot-notation for IPv4 addresses, colon-separated hexadecimal format for IPv6 addresses, or a host name present in the host name database. If a host name is given that expands to more than one address, the requested operation will be performed multiple times, once for each possible combination of addresses.

Identity pairs are made up of a local type-value pair, followed by the remote type-value pair. Valid types are:

|           |                                              |
|-----------|----------------------------------------------|
| prefix    | An address prefix.                           |
| fqdn      | A fully-qualified domain name.               |
| domain    | Domain name, synonym for fqdn.               |
| user_fqdn | User identity of the form <i>user@fqdn</i> . |
| mailbox   | Synonym for <i>user_fqdn</i> .               |

A cookie pair is made up of the two cookies assigned to a Phase 1 Security Association (SA) when it is created; first is the initiator's, followed by the responder's. A cookie is a 64-bit number.

Finally, a label (which is used to identify a policy rule) is a character string assigned to the rule when it is created.

Formatting a rule or preshared key for the add command follows the format rules for the *in.iked* configuration files. Both are made up of a series of id-value pairs, contained in curly braces (*{* and *}*). See *ike.config(4)* and *ike.preshared(4)* for details on the formatting of rules and preshared keys.

## SECURITY

The *ikeadm* command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the *ikeadm* command.

- Is the TTY going over a network (interactive mode)?
  - If it is, then the security of the keying material is the security of the network path for this TTY's traffic. Using *ikeadm* over a clear-text telnet or rlogin session is risky. Even local windows may be vulnerable to attacks where a concealed program that reads window events is present.
- Is the file accessed over the network or readable to the world (read/write commands)?
  - A network-mounted file can be sniffed by an adversary as it is being read. A world-readable file with keying material in it is also risky.

If your source address is a host that can be looked up over the network, and your naming system itself is compromised, then any names used will no longer be trustworthy.

Security weaknesses often lie in misapplication of tools, not the tools themselves. It is recommended that administrators are cautious when using the *ikeadm* command. The safest mode of operation is probably on a console, or other hard-connected TTY.

For additional information regarding this subject, see the afterward by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C*.

ikeadm(1M)

**EXAMPLES**

**EXAMPLE 1** Emptying out all Phase 1 Security Associations

The following command empties out all Phase 1 Security Associations:

```
example# ikeadm flush pls
```

**EXAMPLE 2** Displaying all Phase 1 Security Associations

The following command displays all Phase 1 Security Associations:

```
example# ikeadm dump pls
```

**EXAMPLE 3** Deleting a Specific Phase 1 Security Association

The following command deletes the specified Phase 1 Security Associations:

```
example# ikeadm get pl local_ip remote_ip
```

**EXAMPLE 4** Adding a Rule From a File

The following command adds a rule from a file:

```
example# ikeadm add rule rule_file
```

**EXAMPLE 5** Adding a Preshared Key

The following command adds a preshared key:

```
example# ikeadm
 ikeadm> add preshared { localidtype ip localid local_ip
 remoteidtype ip remoteid remote_ip ike_mode main
 key 1234567890abcdef1234567890abcdef }
```

**EXAMPLE 6** Saving All Preshared Keys to a File

The following command saves all preshared keys to a file:

```
example# ikeadm write preshared target_file
```

**EXAMPLE 7** Viewing a Particular Rule

The following command views a particular rule:

```
example# ikeadm get rule rule_label
```

**EXAMPLE 8** Reading in New Rules from ike.config

The following command reads in new rules from the ike.config file:

```
example# ikeadm read rules
```

**EXAMPLE 9** Lowering the Privilege Level

The following command lowers the privilege level:

```
example# ikeadm set priv base
```

**EXAMPLE 10** Viewing the debug level

The following command the current debug level

```
example# ikeadm get debug
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred. Writes an appropriate error message to standard error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Evolving        |

| <b>DESCRIPTION</b> | <p>The <b>ikecert</b> command manipulates the machine’s on-filesystem public-key certificate databases. See <b>FILES</b>.</p> <p><b>ikecert</b> has three subcommands. one for each of the three major repositories:</p> <ul style="list-style-type: none"><li>■ <b>certlocal</b> deals with the private-key repository,</li><li>■ <b>certdb</b> deals with the public-key repository, and</li><li>■ <b>certldb</b> deals with the certificate revocation list (CRL) repository.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                  |                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                                                                      |                |                                                                                                                                                |                  |                                                                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | <p>Each subcommand requires one option, possibly followed by one or more option-specific arguments.</p> <p>The following options are supported:</p> <p><b>-a</b></p> <table><tr><td><b>certlocal</b></td><td>When specified with the <b>certlocal</b> subcommand, this option installs (adds) a private key into the Internet Key Exchange (IKE) local ID database. The key data is read from standard input, and is in a Solaris-only format.</td></tr><tr><td><b>certdb</b></td><td>When specified with the <b>certdb</b> subcommand, this option reads a certificate from standard input and adds it to the IKE certificate database. The certificate must be a X.509 certificate in PEM Base64 or ASN.1 BER encoding. The certificate adopts the name of its identity.</td></tr><tr><td><b>certldb</b></td><td>When specified with the <b>certldb</b> subcommand, this option installs (adds) a CRL into the IKE database. The CRL reads from standard input.</td></tr></table> <p><b>-e slot</b></p> <table><tr><td><b>certlocal</b></td><td>When specified with the <b>certlocal</b> subcommand, this option extracts a private key from the IKE local ID database. The key data are written to standard output. The <i>lot</i> specifies which private key to extract. Private keys are only extracted in binary/ber format.</td></tr></table> <p><i>Use this option with extreme caution. See SECURITY.</i></p> <p><b>-e [-f output-format] certspec</b></p> <table><tr><td><b>certdb</b></td><td>When specified with the <b>certdb</b> subcommand, this option extracts a certificate from the IKE certificate database which matches the <b>certspec</b> and writes it to standard output. The <i>output-format</i> option specifies the</td></tr></table> | <b>certlocal</b> | When specified with the <b>certlocal</b> subcommand, this option installs (adds) a private key into the Internet Key Exchange (IKE) local ID database. The key data is read from standard input, and is in a Solaris-only format. | <b>certdb</b> | When specified with the <b>certdb</b> subcommand, this option reads a certificate from standard input and adds it to the IKE certificate database. The certificate must be a X.509 certificate in PEM Base64 or ASN.1 BER encoding. The certificate adopts the name of its identity. | <b>certldb</b> | When specified with the <b>certldb</b> subcommand, this option installs (adds) a CRL into the IKE database. The CRL reads from standard input. | <b>certlocal</b> | When specified with the <b>certlocal</b> subcommand, this option extracts a private key from the IKE local ID database. The key data are written to standard output. The <i>lot</i> specifies which private key to extract. The <i>output-format</i> option specifies the |
| <b>certlocal</b>   | When specified with the <b>certlocal</b> subcommand, this option installs (adds) a private key into the Internet Key Exchange (IKE) local ID database. The key data is read from standard input, and is in a Solaris-only format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                                                                      |                |                                                                                                                                                |                  |                                                                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                          |
| <b>certdb</b>      | When specified with the <b>certdb</b> subcommand, this option reads a certificate from standard input and adds it to the IKE certificate database. The certificate must be a X.509 certificate in PEM Base64 or ASN.1 BER encoding. The certificate adopts the name of its identity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                                                                      |                |                                                                                                                                                |                  |                                                                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                          |
| <b>certldb</b>     | When specified with the <b>certldb</b> subcommand, this option installs (adds) a CRL into the IKE database. The CRL reads from standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                  |                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                                                                      |                |                                                                                                                                                |                  |                                                                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                          |
| <b>certlocal</b>   | When specified with the <b>certlocal</b> subcommand, this option extracts a private key from the IKE local ID database. The key data are written to standard output. The <i>lot</i> specifies which private key to extract. Private keys are only extracted in binary/ber format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                                                                      |                |                                                                                                                                                |                  |                                                                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                          |
| <b>certdb</b>      | When specified with the <b>certdb</b> subcommand, this option extracts a certificate from the IKE certificate database which matches the <b>certspec</b> and writes it to standard output. The <i>output-format</i> option specifies the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                  |                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                                                                      |                |                                                                                                                                                |                  |                                                                                                                                                                                                                                                                                   |               |                                                                                                                                                                                                                                          |

- encoding format. Valid options are PEM and BER. This extracts the first matching identity. The default output format is PEM.
- certrlodb** When specified with the `certrlodb` subcommand, this option extracts a CRL from the IKE database. The key data are written to standard output. The `certspec` specifies which CRL that is extracted. The first one that matches in the database is extracted. See `PARAMETERS` for details on `certspec` patterns.
- `-kc -m keysize -t keytype -D dname -A altname[ ... ]`
- certlocal** When specified with the `certlocal` subcommand, this option generates a IKE public/private key pair and adds it into the local ID database. It also generates a certificate request and sends that to standard output. For details on the above options see `PARAMETERS` for details on the `dname` argument and see `ALTERNATIVE NAMES` for details on the `altname` argument(s) to this command.
- `-ks -m keysize -t keytype -D dname -A altname[ ... ] [-f output-format]`
- certlocal** When specified with the `certlocal` subcommand, generates a public/private key pair and add it into the local ID database. This option also generates a self-signed certificate and installs it into the certificate database. See `PARAMETERS` for details on the `dname` and `altname` arguments to this command.
- `-l [ -v ] [slot]`
- certlocal** When specified with the `certlocal` subcommand, this option lists private keys in the local ID database. The `-v` option switches output to a verbose mode where the entire certificate is printed.
- Use the `-v` option with extreme caution. See SECURITY.*
- `-l [ -v ] [certspec]`
- certdb** When specified with the `certdb` subcommand, this option lists certificates in the IKE certificate database matching the `certspec`, if any pattern is given. The list displays the identity string of the certificates; as well as, the private key if in the key database. The `-v` switches the output to a verbose mode where the entire certificate is printed.
- certrlodb** When specified with the `certrlodb` subcommand, this option lists the CRLs in the IKE database along with any certificates that reside in the database and match the Issuer Name. `certspec` can be used to specify to list a specific CRL. The `-v` option switches the output to a verbose mode where the entire certificate is printed. See `PARAMETERS` for details on `certspec` patterns.
- `-r slot`
- certlocal** When specified with the `certlocal` subcommand, deletes the local ID in the specified slot. If there is a corresponding public key, it is not

## ikecert(1M)

be deleted.

-r certspec

**certdb** Removes certificates from the IKE certificate database. Certificates matching the specified certificate pattern are deleted. Any private keys in the `certlocal` database corresponding to these certificates are not deleted. This removes the first matching identity.

**certrl db** When specified with the `certrl db` subcommand, this option deletes the CRL with the given `certspec`.

### PARAMETERS

The following parameters are supported:

**certspec** Specifies the pattern matching of certificate specifications. Valid `certspecs` are the Subject Name, Issuer Name, and Subject Alternative Names.

These can be specified as certificates that match the given `certspec` values and that don't match other `certspec` values. To signify a `certspec` value that is not supposed to be present in a certificate, place an `!` in front of the tag.

Valid `certspecs` are:

```
<Subject Names>
SUBJECT=<Subject Names>
ISSUER=<Issuer Names>
SLOT=<Slot Number in the certificate database>
```

```
Example: "ISSUER=C=US, O=SUN" IP=1.2.3.4 !DNS=example.com
Example: "C=US, O=CALIFORNIA" IP=5.4.2.1 DNS=sun.com
```

Valid arguments to the alternative names are as follows:

```
IP=<IPv4 address>
DNS=<Domain Name Server address>
EMAIL=<email (RFC 822) address>
URI=<Uniform Resource Indicator value>
DN=<LDAP Directory Name value>
RID=<Registered Identifier value>
```

Valid Slot numbers can be specified without the keyword tag. Alternative name can also be issued with keyword tags.

**-A** Subject Alternative Names the certificate. It format that follows the `-A` should be in the form of `tag=value`; where valid tags are IP, DNS, EMAIL, URI, DN, and RID (See example below).

**-D** X.509 distinguished name for the certificate subject. It typically has the form of: C=country, O=organization, OU=organizational unit, CN=common name. Valid tags are: C, O, OU, and CN.

-f	Encoding output format. pem for PEM Base64 or ber for ASN.1 BER. If -f is not specified, pem is assumed.
-m	Key size. It can be 512, 1024, 2048, 3072, or 4096.
-t	Key type. It can be rsa-sha1, rsa-md5, or dsa-sha1.
<b>SECURITY</b>	<p>This command can save private keys of a public-private keypair into a file. Any exposure of a private key may lead to compromise if it the key is somehow obtained by an adversary.</p> <p>Refer to the afterward by Matt Blaze in Bruce Schneier's <i>Applied Cryptography: Protocols, Algorithms, and Source Code in C</i> for additional information.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Generating a Self-Signed Certificate</p> <p>The following is an example of a self-signed certificate:</p> <pre># ikecert certlocal -ks -m 512 -t rsa-md5 -D "C=US, O=SUN" -A IP=1.2.3.4 Generating, please wait... Certificate generated. Certificate added to database. -----BEGIN X509 CERTIFICATE----- MIIBRDCB76ADAgECAGEBMA0GCSqGSIb3DQEBAUAMBsxCzAJBgNVBAYTAlVTMQww CgYDVQQKEwNTVU4wHhcNMDEwMzE0MDEzMDE1WhcNMDEwMzE0MDEzMDE1WjAbMQsw CQYDVQQGEwJVUzEMMAoGA1UEChMDU1VOMFowDQYJKoZIhvcNAQEBBQADSAwRgJB APDhqKgjgRoUR6twTMTtSuNsReEnFoReVer!ztpXpQK6ybY1RH18JIqU/ucV/r 26R/cVXTy5qc5NbMwA40KzcCASOjIDAeMAsGA1UdDwQEAwIFoDAPBgNVHREECDAg hwQBAGMEMA0GCSqGSIb3DQEBAUAA0EApTRD23KzN95GMvPD71hwwCluks1KLVg8 f1xm9ZsHLPJLRxHFwsqqjAad4j4wwwriiUmGAHLTGB0lJm18xsqxag== -----END X509 CERTIFICATE-----</pre> <p><b>EXAMPLE 2</b> Generating a CA Request</p> <p>Generating a CA request appears the same as the self-signed certificate. The only differences between the two is the option -c instead of -s , and the certificate data is a CA request.</p> <pre># ikecert certlocal -kc -m 512 -t rsa-md5 \ -D "C=US, O=SUN" -A IP=1.2.3.4</pre>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>non-zero An error occurred. Writes an appropriate error message to standard error.</p>
<b>FILES</b>	<p>/etc/inet/secret/ike.privatekeys/*</p> <p>Private keys. A private key <i>must</i> have a matching public-key certificate with the same filename in /etc/inet/ike/publickeys/.</p>

ikecert(1M)

/etc/inet/ike/publickeys/\*

Public-key certificates. The names are only important with regard to matching private key names.

/etc/inet/ike/crls/\*

Public key certificate revocation lists.

<b>NAME</b>	in.comsat, comsat – biff server				
<b>SYNOPSIS</b>	<code>/usr/sbin/in.comsat</code>				
<b>DESCRIPTION</b>	<p>comsat is the server process which listens for reports of incoming mail and notifies users who have requested to be told when mail arrives. It is invoked as needed by inetd(1M), and times out if inactive for a few minutes.</p> <p>comsat listens on a datagram port associated with the biff service specification (see services(4)) for one line messages of the form</p> <p><i>user@mailbox-offset</i></p> <p>If the <i>user</i> specified is logged in to the system and the associated terminal has the owner execute bit turned on (by a biff <i>y</i>), the <i>offset</i> is used as a seek offset into the appropriate mailbox file, and the first 7 lines or 560 characters of the message are printed on the user's terminal. Lines which appear to be part of the message header other than the From, To, Date, or Subject lines are not printed when displaying the message.</p>				
<b>FILES</b>	<code>/var/adm/utmpx</code> user access and administration information				
<b>ATTRIBUTES</b>	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWrcmds</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmds
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWrcmds				
<b>SEE ALSO</b>	inetd(1M), services(4), attributes(5)				
<b>NOTES</b>	The message header filtering is prone to error.				

## in.dhcpd(1M)

<b>NAME</b>	in.dhcpd – Dynamic Host Configuration Protocol server
<b>SYNOPSIS</b>	<pre><b>/usr/lib/inet/in.dhcpd</b> [-denv] [-h <i>relay_hops</i>] [-i <i>interface, ...</i>] [-l <i>syslog_local_facility</i>] [-b <i>automatic   manual</i>] [-o <i>DHCP_offer_time</i>] [-t <i>dhcptab_rescan_interval</i>]  <b>/usr/lib/inet/in.dhcpd</b> [-dv] [-h <i>relay_hops</i>] [-i <i>interface,...</i>] [-l <i>syslog_local_facility</i>] -r <i>IP_address   hostname, ...</i></pre>
<b>DESCRIPTION</b>	<p>in.dhcpd is a daemon that responds to Dynamic Host Configuration Protocol (DHCP) requests and optionally to BOOTP protocol requests. The daemon forks a copy of itself that runs as a background process. It must be run as root. The daemon has two run modes, DHCP server (with optional BOOTP compatibility mode) and BOOTP relay agent mode.</p> <p>The first line in the SYNOPSIS section illustrates the options available in the DHCP/BOOTP server mode. The second line in the SYNOPSIS section illustrates the options available when the daemon is run in BOOTP relay agent mode.</p> <p>The DHCP and BOOTP protocols are used to provide configuration parameters to Internet hosts. Client machines are allocated their IP addresses as well as other host configuration parameters through this mechanism.</p> <p>The DHCP/BOOTP daemon manages two types of DHCP data tables: the dhcptab configuration table and the DHCP network tables.</p> <p>See dhcptab(4) regarding the dhcptab configuration table and dhcp_network(4) regarding the DHCP network tables.</p> <p>The dhcptab contains macro definitions defined using a termcap-like syntax which permits network administrators to define groups of DHCP configuration parameters to be returned to clients. However, a DHCP/BOOTP server always returns hostname, network broadcast address, network subnet mask, and IP maximum transfer unit (MTU) if requested by a client attached to the same network as the server machine. If those options have not been explicitly configured in the dhcptab, in.dhcpd returns reasonable default values.</p> <p>The dhcptab is read at startup, upon receipt of a SIGHUP signal, or periodically as specified by the -t option. A SIGHUP (sent using the command <code>pkill -HUP in.dhcpd</code>) causes the DHCP/BOOTP daemon to reread the dhcptab within an interval from 0-60 seconds (depending on where the DHCP daemon is in its polling cycle). For busy servers, users should run <code>/etc/init.d/dhcp stop</code>, followed by <code>/etc/init.d/dhcp start</code> to force the dhcptab to be reread.</p> <p>The DHCP network tables contain mappings of client identifiers to IP addresses. These tables are named after the network they support and the datastore used to maintain them.</p> <p>The DHCP network tables are consulted during runtime. A client request received from a network for which no DHCP network table exists is ignored.</p>

This command may change in future releases of Solaris software. Scripts, programs, or procedures that use this command might need modification when upgrading to future Solaris software releases. The command line options provided with the `in.dhcpd` daemon are used only for the current session, and include only some of the server options you can set. The `dhcpsvc.conf(4)` contains all the server default settings, and can be modified by using the `dhcprmgr` utility. See `dhcpsvc.conf(4)` for more details.

#### OPTIONS The following options are supported:

`-b automatic | manual`

This option enables BOOTP compatibility mode, allowing the DHCP server to respond to BOOTP clients. The option argument specifies whether the DHCP server should automatically allocate permanent lease IP addresses to requesting BOOTP clients if the clients are not registered in the DHCP network tables (`automatic`) or respond only to BOOTP clients who have been manually registered in the DHCP network tables (`manual`). This option only affects DHCP server mode.

`-d`

Debugging mode. The daemon remains as a foreground process, and displays verbose messages as it processes DHCP and/or BOOTP datagrams. Messages are displayed on the current TTY. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

`-h relay_hops`

Specifies the maximum number of relay agent hops that can occur before the daemon drops the DHCP/BOOTP datagram. The default number of relay agent hops is 4. This option affects both DHCP/BOOTP server mode and BOOTP relay agent mode.

`-i interface, . . .`

Selects the network interfaces that the daemon should monitor for DHCP/BOOTP datagrams. The daemon ignores DHCP/BOOTP datagrams on network interfaces not specified in this list. This option is only useful on machines that have multiple network interfaces. If this option is not specified, then the daemon listens for DHCP/BOOTP datagrams on all network interfaces. The option argument consists of a comma-separated list of interface names. It affects both DHCP/BOOTP server and BOOTP relay agent run modes.

`-l syslog_local_facility`

The presence of this option turns on transaction logging for the DHCP server or BOOTP relay agent. The value specifies the `syslog` local facility (an integer from 0 to 7 inclusive) the DHCP daemon should use for tagging the transactions. Using a facility separate from the `LOG_DAEMON` facility allows the network administrator to capture these transactions separately from other DHCP daemon events for such purposes as generating transaction reports. See `syslog(3C)`, for details about local facilities. Transactions are logged using a record with 9 space-separated fields as follows:

1. Protocol:

in.dhcpd(1M)

Relay mode: "BOOTP"  
Server mode: "BOOTP" or "DHCP" based upon client type.

2. Type:

Relay mode: "RELAY-CLNT", "RELAY-SRVR"  
Server mode: "ASSIGN", "EXTEND", "RELEASE",  
"DECLINE", "INFORM", "NAK" "ICMP-ECHO."

3. Transaction time: absolute time in seconds (unix time)

4. Lease time:

Relay mode: Always 0.  
Server mode: 0 for ICMP-ECHO events, absolute time in seconds (unix time) otherwise

5. Source IP address: Dotted Internet form

Relay mode: Relay interface IP on RELAY-CLNT,  
INADDR\_ANY on RELAY-SRVR.  
Server mode: Client IP.

6. Destination IP address: Dotted Internet form

Relay mode: Client IP on RELAY-CLNT, Server IP on  
RELAY-SRVR.  
Server mode: Server IP.

7. Client Identifier: Hex representation (0-9, A-F)

Relay mode: MAC address  
Server mode: BOOTP - MAC address; DHCP - client id

8. Vendor Class identifier (white space converted to periods (.)).

Relay mode: Always "N/A"  
Server mode: Vendor class ID tokenized by  
converting white space characters  
to periods (.)

9. MAC address: Hex representation (0-9, A-F)

Relay mode: MAC address  
Server mode: MAC address

The format of this record is subject to change between releases.

Transactions are logged to the console if daemon is in debug mode (-d).

Logging transactions impact daemon performance.

It is suggested that you manage log file size periodically using a script run by `cron(1M)` and sending `syslogd(1M)` a `SIGHUP` signal. You could, for example, clone `/usr/lib/newsyslog` and alter it to match your DHCP logging requirements.

-n

Disable automatic duplicate IP address detection. When this option is specified, the DHCP server does not attempt to verify that an IP address it is about to offer a client is not in use. By default, the DHCP server pings an IP address before offering it to a DHCP/BOOTP client, to verify that the address is not in use by another machine.

-o *DHCP\_offer\_time*

Specifies the number of seconds the DHCP server should cache the offers it has extended to discovering DHCP clients. The default setting is 10 seconds. On slow network media, this value can be increased to compensate for slow network performance. This option affects only DHCP server mode.

-r *IP\_address | hostname, . . .*

This option enables BOOTP relay agent mode. The option argument specifies a comma-separated list of IP addresses or hostnames of DHCP or BOOTP servers to which the relay agent is to forward BOOTP requests. When the daemon is started in this mode, any DHCP tables are ignored, and the daemon simply acts as a BOOTP relay agent.

A BOOTP relay agent listens to UDP port 68, and forwards BOOTP request packets received on this port to the destinations specified on the command line. It supports the `BROADCAST` flag described in RFC 1542. A BOOTP relay agent can run on any machine that has knowledge of local routers, and thus does not have to be an Internet gateway machine.

Note that the proper entries must be made to the `netmasks` database so that the DHCP server being served by the BOOTP relay agents can identify the subnet mask of the foreign BOOTP/DHCP client's network. See `netmasks(4)` for the format and use of this database.

-t *dhcptab\_rescan\_interval*

Specifies the interval in minutes that the DHCP server should use to schedule the automatic rereading of the `dhcptab` information. Typically, you would use this option if the changes to the `dhcptab` are relatively frequent. Once the contents of the `dhcptab` have stabilized, you can turn off this option to avoid needless reinitialization of the server.

-v

Verbose mode. The daemon displays more messages than in the default mode. Note that verbose mode can reduce daemon efficiency due to the time taken to display messages. Messages are displayed to the current TTY if the debugging option is used; otherwise, messages are logged to the `syslogd` facility. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

## in.dhcpd(1M)

### EXAMPLES

#### EXAMPLE 1 Starting a DHCP Server in BOOTP Compatibility Mode

The following command starts a DHCP server in BOOTP compatibility mode, permitting the server to automatically allocate permanent IP addresses to BOOTP clients which are not registered in the server's table; limits the server's attention to incoming datagrams on network devices `le2` and `tr0`; drops BOOTP packets whose hop count exceeds 2; configures the DHCP server to cache extended DHCP offers for 15 seconds; and schedules `dhcptab` rescans to occur every 10 minutes:

```
in.dhcpd -i le2,tr0 -h 2 -o 15 -t 10 -b automatic
```

#### EXAMPLE 2 Starting the Daemon in BOOTP Relay Agent Mode

The following command starts the daemon in BOOTP relay agent mode, registering the hosts `bladerunner` and `10.0.0.5` as relay destinations, with debugging and verbose modes enabled, and drops BOOTP packets whose hop count exceeds 5:

```
in.dhcpd -d -v -h 5 -r bladerunner,10.0.0.5
```

### FILES

```
/etc/inet/dhcpsvc.conf
/etc/init.d/dhcp
/etc/init/hosts
/usr/lib/inet/dhcp/nsu/rfc2136.so.1
```

## inetd(1M)

<b>NAME</b>	inetd – Internet services daemon
<b>SYNOPSIS</b>	<b>inetd</b> [-d] [-s] [-t] [-r <i>count interval</i> ] [ <i>configuration-file</i> ]
<b>DESCRIPTION</b>	<p>inetd is the server process for the Internet standard services. It is usually started up at system boot time. The <i>configuration-file</i> lists the services that inetd is to provide. If no <i>configuration-file</i> is given on the command line, inetd reads its configuration information from the file <code>/etc/inetd.conf</code>. See <code>inetd.conf(4)</code> for more information on the format of this file. inetd listens for service requests on the TCP or UDP ports associated with each of the services listed in the configuration file. When a request arrives, inetd executes the server program associated with the service.</p> <p>A service can be configured to have "wait" wait-status, in which case, inetd waits for the server process to exit before starting a second server process. RPC services can also be started by inetd.</p> <p>inetd provides a number of simple Internet services internally. These include <code>echo</code>, <code>discard</code>, <code>chargen</code> (character generator), <code>daytime</code> (human-readable time), and <code>time</code> (machine-readable time, in the form of the number of seconds since midnight, January 1, 1900).</p> <p>inetd rereads its <i>configuration-file</i> once when it is started and again whenever it receives a hangup signal, <code>SIGHUP</code>. New services can be activated and existing services can be deleted or modified by editing the <i>configuration-file</i>, then sending inetd a <code>SIGHUP</code> signal.</p> <p>After it receives the <code>SIGHUP</code> signal, inetd reads the <i>configuration-file</i> and, for each service listed, attempts to <code>bind()</code> to that service's port. The attempt might fail if another standalone server or "wait" wait-status server started by inetd is already listening on the same port. (Such a server has to be killed before inetd can bind to the service's port.) inetd defers implementing a newly read configuration for a service whose port is busy and periodically attempts to start listening, after logging an error on console. The retry interval is currently 10 minutes.</p> <p>If you want a "wait" wait-status server that is started by inetd to be controlled by that daemon following a kill and restart of inetd, you must do one of the following:</p> <ul style="list-style-type: none"><li>■ Kill the server before restarting inetd.</li><li>■ Restart inetd, kill the server, and wait till the retry interval elapses, after which inetd attempts to restart the server upon the next request for service.</li></ul>
<b>OPTIONS</b>	<p>-d       Runs inetd in the foreground and enables debugging output.</p> <p>-s       Allows you to run inetd "stand-alone," outside the Service Access Facility ("SAF"). If the -s option is omitted, inetd will attempt to contact the service access controller ("SAC") and will exit if SAC is not already running. See <code>sac(1M)</code></p> <p>-t       Instructs inetd to trace the incoming connections for all of its TCP services. It does this by logging the client's IP address and TCP port</p>

number, along with the name of the service, using the `syslog(3C)` facility. "Wait" wait-status services cannot be traced. When tracing is enabled, `inetd` uses the `syslog` facility code "daemon" and "notice" priority level.

`-r` Allows `inetd` to detect and then suspend "broken" "wait" services servers and connectionless datagram services servers, for example, UDP, and RPC/CLTS. Without this detection, a buggy server that fails before consuming the service request will be continuously restarted and will tax system resources too much. The `-r` flag has the form:

`-r count intervalcount` and `interval` are decimal numbers that represent the maximum `count` of invocations per `interval` of seconds a service may be started before the service is considered "broken."

Once considered "broken," a server is suspended for ten minutes. After ten minutes, `inetd` again enables service, hoping the server behaves correctly.

If the `-r` flag is not specified, `inetd` behaves as though `-r40 60` was specified.

**OPERANDS** `configuration-file` Lists the services `inetd` is to provide.

**EXIT STATUS** `inetd` does not return an exit status.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `in.ftpd(1M)`, `in.rexecd(1M)`, `in.rshd(1M)`, `in.tftpd(1M)`, `sac(1M)`, `syslog(3C)`, `inetd.conf(4)`, `attributes(5)`

## inetd(1M)

**WARNINGS** Do not configure udp services as `nowait`. This will cause a race condition where the `inetd` program selects on the socket and the server program reads from the socket. Many server programs will be forked and performance will be severely compromised.

If you kill and restart `inetd`, be aware that any environment variables in your shell are inherited by a shell for an incoming `telnet` session. For example, if you have `USER=root` in your environment, a user who connects to your machine with `telnet` inherits `USER=root`.

**NOTES** For RPC services, `inetd` listens on all the transports (not only `tcp` and `udp`) as specified for each service in the `inetd.conf(4)` file.

<b>NAME</b>	in.fingerd, fingerd – remote user information server										
<b>SYNOPSIS</b>	<code>/usr/sbin/in.fingerd</code>										
<b>DESCRIPTION</b>	<p>fingerd implements the server side of the Name/Finger protocol, specified in <i>RFC 742</i>. The Name/Finger protocol provides a remote interface to programs which display information on system status and individual users. The protocol imposes little structure on the format of the exchange between client and server. The client provides a single command line to the finger server which returns a printable reply.</p> <p>fingerd waits for connections on TCP port 79. Once connected, it reads a single command line terminated by RETURN-LINEFEED and passes the arguments to finger(1), prepended with -s. fingerd closes its connections as soon as the output is finished.</p> <p>You must invoke fingerd from inetd. See inetd(1M) for more information.</p>										
<b>FILES</b>	<table border="0"> <tr> <td><code>/var/adm/utmpx</code></td> <td>User and accounting information.</td> </tr> <tr> <td><code>/etc/passwd</code></td> <td>System password file.</td> </tr> <tr> <td><code>/var/adm/lastlog</code></td> <td>Last login times.</td> </tr> <tr> <td><code>\$HOME/.plan</code></td> <td>User's plans.</td> </tr> <tr> <td><code>\$HOME/.project</code></td> <td>User's projects.</td> </tr> </table>	<code>/var/adm/utmpx</code>	User and accounting information.	<code>/etc/passwd</code>	System password file.	<code>/var/adm/lastlog</code>	Last login times.	<code>\$HOME/.plan</code>	User's plans.	<code>\$HOME/.project</code>	User's projects.
<code>/var/adm/utmpx</code>	User and accounting information.										
<code>/etc/passwd</code>	System password file.										
<code>/var/adm/lastlog</code>	Last login times.										
<code>\$HOME/.plan</code>	User's plans.										
<code>\$HOME/.project</code>	User's projects.										
<b>USAGE</b>	fingerd and in.fingerd are IPv6-enabled. See ip6(7P).										
<b>ATTRIBUTES</b>	See attributes(5) for descriptions of the following attributes:										
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWrcmds</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmds						
ATTRIBUTE TYPE	ATTRIBUTE VALUE										
Availability	SUNWrcmds										
<b>SEE ALSO</b>	<p>finger(1), inetd(1M), inetd.conf(4), attributes(5), ip6(7P)</p> <p>Harrenstien, Ken, <i>RFC 742, NAME/FINGER</i>, Network Information Center, SRI International, Menlo Park, Calif., December 1977.</p>										
<b>NOTES</b>	Connecting directly to the server from a TIP or an equally narrow-minded TELNET-protocol user program can result in meaningless attempts at option negotiation being sent to the server, which will foul up the command line interpretation. fingerd should be taught to filter out IAC's and perhaps even respond negatively (IAC will not) to all option commands received.										

## infocmp(1M)

<b>NAME</b>	infocmp – compare or print out terminfo descriptions
<b>SYNOPSIS</b>	<pre><b>/usr/bin/infocmp</b> [-d] [-c] [-n] [-I] [-L] [-C] [-r] [-u] [-s   d   i   l   c] [-v] [-V] [-1] [-w <i>width</i>] [-A <i>directory</i>] [-B <i>directory</i>] [<i>termname</i>...]</pre>
<b>DESCRIPTION</b>	<p>infocmp compares a binary <code>terminfo</code> entry with other <code>terminfo</code> entries, rewrites a <code>terminfo</code> description to take advantage of the <code>use=</code> <code>terminfo</code> field, or prints out a <code>terminfo</code> description from the binary file (<code>term</code>) in a variety of formats. It displays boolean fields first, then numeric fields, followed by the string fields. If no options are specified and zero, or one <i>termname</i> is specified, the <code>-I</code> option is assumed. If more than one <i>termname</i> is specified, the <code>-d</code> option is assumed.</p>
<b>OPTIONS</b>	<p>The <code>-d</code>, <code>-c</code>, and <code>-n</code> options can be used for comparisons. <code>infocmp</code> compares the <code>terminfo</code> description of the first terminal <i>termname</i> with each of the descriptions given by the entries for the other terminal's <i>termname</i>. If a capability is defined for only one of the terminals, the value returned will depend on the type of the capability: <code>F</code> for boolean variables, <code>-1</code> for integer variables, and <code>NULL</code> for string variables.</p> <ul style="list-style-type: none"><li><code>-d</code> Produce a list of each capability that is different between two entries. This option is useful to show the difference between two entries, created by different people, for the same or similar terminals.</li><li><code>-c</code> Produce a list of each capability that is common between two entries. Capabilities that are not set are ignored. This option can be used as a quick check to see if the <code>-u</code> option is worth using.</li><li><code>-n</code> Produce a list of each capability that is in neither entry. If no <i>termname</i> is given, the environment variable <code>TERM</code> will be used for both of the <i>termnames</i>. This can be used as a quick check to see if anything was left out of a description.</li></ul> <p>The <code>-I</code>, <code>-L</code>, and <code>-C</code> options will produce a source listing for each terminal named.</p> <ul style="list-style-type: none"><li><code>-I</code> Use the <code>terminfo</code> names.</li><li><code>-L</code> Use the long <code>C</code> variable name listed in <code>&lt;term.h&gt;</code>.</li><li><code>-C</code> Use the <code>termcap</code> names. The source produced by the <code>-C</code> option may be used directly as a <code>termcap</code> entry, but not all of the parameterized strings may be changed to the <code>termcap</code> format. <code>infocmp</code> will attempt to convert most of the parameterized information, but anything not converted will be plainly marked in the output and commented out. These should be edited by hand.</li><li><code>-r</code> When using <code>-C</code>, put out all capabilities in <code>termcap</code> form.</li></ul> <p>If no <i>termname</i> is given, the environment variable <code>TERM</code> will be used for the terminal name.</p>

All padding information for strings will be collected together and placed at the beginning of the string where `termcap` expects it. Mandatory padding (padding information with a trailing `'/'`) will become optional.

All `termcap` variables no longer supported by `terminfo`, but are derivable from other `terminfo` variables, will be displayed. Not all `terminfo` capabilities will be translated; only those variables which were part of `termcap` will normally be displayed. Specifying the `-r` option will take off this restriction, allowing all capabilities to be displayed in `termcap` form.

Note that because padding is collected to the beginning of the capability, not all capabilities are displayed. Mandatory padding is not supported. Because `termcap` strings are not as flexible, it is not always possible to convert a `terminfo` string capability into an equivalent `termcap` format. A subsequent conversion of the `termcap` file back into `terminfo` format will not necessarily reproduce the original `terminfo` source.

Some common `terminfo` parameter sequences, their `termcap` equivalents, and some terminal types which commonly have such sequences, are:

<code>terminfo</code>	<code>termcap</code>	Representative Terminals
<code>%p1%c</code>	<code>%. adm</code>	
<code>%p1%d</code>	<code>%d hp, ANSI standard, vt100</code>	
<code>%p1%'x'%'%+c</code>	<code>%+x concept</code>	
<code>%i</code>	<code>%i ANSI standard, vt100</code>	
<code>%p1%?'x'%'&gt;%t%p1%'y'%'%+%;</code>	<code>%&gt;xy concept</code>	
<code>%p2 is printed before %p1</code>	<code>%r hp</code>	

`-u` Produce a `terminfo` source description of the first terminal *termname* which is relative to the sum of the descriptions given by the entries for the other terminals' *termnames*. It does this by analyzing the differences between the first *termname* and the other *termnames* and producing a description with `use=` fields for the other terminals. In this manner, it is possible to retrofit generic `terminfo` entries into a terminal's description. Or, if two similar terminals exist, but were coded at different times, or by different people so that each description is a full description, using `infocmp` will show what can be done to change one description to be relative to the other.

A capability is displayed with an at-sign (`@`) if it no longer exists in the first *termname*, but one of the other *termname* entries contains a value for it. A capability's value is displayed if the value in the first *termname* is not found in any of the other *termname* entries, or if the first of the other *termname* entries that has this capability gives a different value for that capability.

The order of the other *termname* entries is significant. Since the `terminfo` compiler `tic` does a left-to-right scan of the capabilities, specifying two `use=` entries that contain differing entries for the same capabilities will produce different results,

## infocmp(1M)

depending on the order in which the entries are given. `infocmp` will flag any such inconsistencies between the other *termname* entries as they are found.

Alternatively, specifying a capability *after* a `use=` entry that contains, it will cause the second specification to be ignored. Using `infocmp` to recreate a description can be a useful check to make sure that everything was specified correctly in the original source description.

Another error that does not cause incorrect compiled files, but will slow down the compilation time, is specifying superfluous `use=` fields. `infocmp` will flag any superfluous `use=` fields.

`-s` Sorts the fields within each type according to the argument below:

- `d` Leave fields in the order that they are stored in the `terminfo` database.
- `i` Sort by `terminfo` name.
- `l` Sort by the long C variable name.
- `c` Sort by the `termcap` name.

If the `-s` option is not given, the fields are sorted alphabetically by the `terminfo` name within each type, except in the case of the `-C` or the `-L` options, which cause the sorting to be done by the `termcap` name or the long C variable name, respectively.

`-v` Print out tracing information on standard error as the program runs.

`-V` Print out the version of the program in use on standard error and exit.

`-l` Print the fields one to a line. Otherwise, the fields are printed several to a line to a maximum width of 60 characters.

`-width` Changes the output to *width* characters.

The location of the compiled `terminfo` database is taken from the environment variable `TERMINFO`. If the variable is not defined, or the terminal is not found in that location, the system `terminfo` database, usually in `/usr/share/lib/terminfo`, is used. The options `-A` and `-B` may be used to override this location.

`-A directory` Set `TERMINFO` for the first *termname*.

`-B directory` Set `TERMINFO` for the other *termnames*. With this, it is possible to compare descriptions for a terminal with the same name located in two different databases. This is useful for comparing descriptions for the same terminal created by different people.

**FILES** `/usr/share/lib/terminfo/?/*` Compiled terminal description database.

## in.ftpd(1M)

<b>NAME</b>	in.ftpd, ftpd – File Transfer Protocol Server
<b>SYNOPSIS</b>	<b>in.ftpd</b> [-A] [-a] [-d] [-I] [-i] [-L] [-l] [-o] [-P <i>dataport</i> ] [-p <i>ctrlport</i> ] [-Q] [-q] [-r <i>rootdir</i> ] [-S] [-s] [-T <i>maxtimeout</i> ] [-t <i>timeout</i> ] [-u <i>umask</i> ] [-V] [-v] [-W] [-w] [-X]
<b>DESCRIPTION</b>	<i>in.ftpd</i> is the Internet File Transfer Protocol (FTP) server process. The server may be invoked by the Internet daemon <i>inetd</i> (1M) each time a connection to the FTP service is made or run as a standalone server. See <i>services</i> (4).
<b>OPTIONS</b>	<i>in.ftpd</i> supports the following options: <ul style="list-style-type: none"><li>-A Disable use of the <i>ftppaccess</i>(4) file. Use of <i>ftppaccess</i> is disabled by default.</li><li>-a Enable use of the <i>ftppaccess</i>(4) file.</li><li>-d Write debugging information to <i>syslogd</i>(1M).</li><li>-I Disable the use of <i>AUTH</i> and <i>ident</i> to determine the username on the client. See <i>RFC 931</i>. The FTP Server is built not to use <i>AUTH</i> and <i>ident</i>.</li><li>-i Log the names of all files received by the FTP Server to <i>xferlog</i>(4). You can override the <i>-i</i> option through use of the <i>ftppaccess</i>(4) file.</li><li>-L Log all commands sent to <i>in.ftpd</i> to <i>syslogd</i>(1M). When the <i>-L</i> option is used, command logging will be on by default, once the FTP Server is invoked. Because the FTP Server includes <i>USER</i> commands in those logged, if a user accidentally enters a password instead of the username, the password will be logged. You can override the <i>-L</i> option through use of the <i>ftppaccess</i>(4) file.</li><li>-l Log each FTP session to <i>syslogd</i>(1M).</li><li>-o Log the names of all files transmitted by the FTP Server to <i>xferlog</i>(4). You can override the <i>-o</i> option through use of the <i>ftppaccess</i>(4) file.</li><li>-P <i>dataport</i> The FTP Server determines the port number by looking in the <i>services</i>(4) file for an entry for the <i>ftp-data</i> service. If there is no entry, the daemon uses the port just prior to the control connection port. Use the <i>-P</i> option to specify the data port number.</li><li>-p <i>ctrlport</i> When run in standalone mode, the FTP Server determines the control port number by looking in the <i>services</i>(4) file for an entry for the <i>ftp</i> service. Use the <i>-p</i> option to specify the control port number.</li></ul>

-Q	Disable PID files. This disables user limits. Large, busy sites that do not want to impose limits on the number of concurrent users can use this option to disable PID files.
-q	Use PID files. The <code>limit</code> directive uses PID files to determine the number of current users in each access class. By default, PID files are used.
-r <i>rootdir</i>	<code>chroot(2)</code> to <i>rootdir</i> upon loading. Use this option to improve system security. It limits the files that can be damaged should a break in occur through the daemon. This option is similar to anonymous FTP. Additional files are needed, which vary from system to system.
-S	Place the daemon in standalone operation mode. The daemon runs in the background. This is useful for startup scripts that run during system initialization. See <code>init.d(4)</code> .
-s	Place the daemon in standalone operation mode. The daemon runs in the foreground. This is useful when run from <code>/etc/inittab</code> by <code>init(1M)</code> .
-T <i>maxtimeout</i>	Set the maximum allowable timeout period to <i>maxtimeout</i> seconds. The default maximum timeout limit is 7200 second (two hours). You can override the <code>-T</code> option through use of the <code>ftppaccess(4)</code> file.
-t <i>timeout</i>	Set the inactivity timeout period to <i>timeout</i> seconds. The default timeout period is 900 seconds (15 minutes). You can override the <code>-t</code> option through use of the <code>ftppaccess(4)</code> file.
-u <i>umask</i>	Set the default <code>umask</code> to <i>umask</i> .
-V	Display copyright and version information, then terminate.
-v	Write debugging information to <code>syslogd(1M)</code> .
-W	Do not record user <code>login</code> and <code>logout</code> in the <code>wtmpx(4)</code> file.
-w	Record each user <code>login</code> and <code>logout</code> in the <code>wtmpx(4)</code> file. By default, logins and logouts are recorded.
-X	Write the output from the <code>-i</code> and <code>-o</code> options to the <code>syslogd(1M)</code> file instead of <code>xferlog(4)</code> . This allows the collection of output from several hosts on one central loghost. You can override the <code>-X</code> option through use of the <code>ftppaccess(4)</code> file.

**Requests** The FTP Server currently supports the following FTP requests; case is not distinguished.

ABOR	Abort previous command.
ALLO	Allocate storage (vacuously).

## in.ftpd(1M)

APPE	Append to a file.
CDUP	Change to parent of current working directory.
CWD	Change working directory.
DELE	Delete a file.
EPRT	Specify extended address for the transport connection.
EPSV	Extended passive command request.
HELP	Give help information.
LIST	Give list files in a directory ( <i>ls -lA</i> ).
LPRT	Specify long address for the transport connection.
LPSV	Long passive command request.
MKD	Make a directory.
MDTM	Show last time file modified.
MODE	Specify data transfer <i>mode</i> .
NLST	Give name list of files in directory ( <i>ls</i> ).
NOOP	Do nothing.
PASS	Specify password.
PASV	Prepare for server-to-server transfer.
PORT	Specify data connection port.
PWD	Print the current working directory.
QUIT	Terminate session.
REST	Restart incomplete transfer.
RETR	Retrieve a file.
RMD	Remove a directory.
RNFR	Specify rename-from file name.
RNTO	Specify rename-to file name.
SITE	Use nonstandard commands.
SIZE	Return size of file.
STAT	Return status of server.
STOR	Store a file.
STOU	Store a file with a unique name.
STRU	Specify data transfer <i>structure</i> .

SYST	Show operating system type of server system.
TYPE	Specify data transfer type.
USER	Specify user name.
XCUP	Change to parent of current working directory. This request is deprecated.
XCWD	Change working directory. This request is deprecated.
XMKD	Make a directory. This request is deprecated.
XPWD	Print the current working directory. This request is deprecated.
XRMD	Remove a directory. This request is deprecated.

The following nonstandard or UNIX specific commands are supported by the SITE request:

ALIAS	List aliases.
CDPATH	List the search path used when changing directories.
CHECKMETHOD	List or set the checksum method.
CHECKSUM	Give the checksum of a file.
CHMOD	Change mode of a file. For example, SITE CHMOD 755 <i>filename</i> .
EXEC	Execute a program. For example, SITE EXEC program params
GPASS	Give special group access password. For example, SITE GPASS bar.
GROUP	Request special group access. For example, SITE GROUP foo.
GROUPS	List supplementary group membership.
HELP	Give help information. For example, SITE HELP.
IDLE	Set idle-timer. For example, SITE IDLE 60.
UMASK	Change umask. For example, SITE UMASK 002.

The remaining FTP requests specified in *RFC 959* are recognized, but not implemented.

The FTP server will abort an active file transfer only when the ABOR command is preceded by a Telnet "Interrupt Process" (IP) signal and a Telnet "Synch" signal in the command Telnet stream, as described in *RFC 959*. If a STAT command is received during a data transfer that has been preceded by a Telnet IP and Synch, transfer status will be returned.

## in.ftpd(1M)

`in.ftpd` interprets file names according to the “globbing” conventions used by `csh(1)`. This allows users to utilize the metacharacters: `* ? [ ] { } ~`

`in.ftpd` authenticates users according to four rules.

First, the user name must be in the password data base, `/etc/passwd`. The password must not be null. A password must always be provided by the client before any file operations may be performed. The PAM framework is used to verify that the correct password was entered. See `SECURITY` below.

Second, the user name must not appear in either the `/etc/ftpusers` or the `/etc/ftpd/ftpusers` file. Use of the `/etc/ftpusers` files is deprecated, although it is still supported.

Third, the user must have a standard shell returned by `getusershell(3C)`.

Fourth, if the user name is `anonymous` or `ftp`, an anonymous `ftp` account must be present in the password file for user `ftp`. Use `ftpconfig(1M)` to create the anonymous `ftp` account and home directory tree.

The FTP Server supports virtual hosting, which can be configured by using `ftpaddhost(1M)`.

The FTP Server does not support sublogins.

### General FTP Extensions

The FTP Server has certain extensions. If the user specifies a filename that does not exist with a `RETR` (retrieve) command, the FTP Server looks for a conversion to change a file or directory that does into the one requested. See `ftpconversions(4)`.

By convention, anonymous users supply their email address when prompted for a password. The FTP Server attempts to validate these email addresses. A user whose FTP client hangs on a long reply, for example, a multiline response, should use a dash (-) as the first character of the user's password, as this disables the Server's `lreply()` function.

The FTP Server can also log all file transmission and reception. See `xferlog(4)` for details of the log file format.

The `SITE EXEC` command may be used to execute commands in the `/bin/ftp-exec` directory. Take care that you understand the security implications before copying any command into the `/bin/ftp-exec` directory. For example, do not copy in `/bin/sh`. This would enable the user to execute other commands through the use of `sh -c`. If you have doubts about this feature, do not create the `/bin/ftp-exec` directory.

### SECURITY

`in.ftpd` uses `pam(3PAM)` for authentication, account management, and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the module to be used for `in.ftpd`. Here is a partial `pam.conf` file with entries for the `in.ftpd` command using the UNIX authentication, account management, and session management module.

in.ftpd(1M)

ftp	auth	required	/usr/lib/security/pam_unix.so.1
ftp	account	required	/usr/lib/security/pam_unix.so.1
ftp	session	required	/usr/lib/security/pam_unix.so.1

If there are no entries for the ftp service, then the entries for the "other" service will be used. Unlike login, passwd, and other commands, the ftp protocol will only support a single password. Using multiple modules will prevent in.ftpd from working properly.

**USAGE** The in.ftpd command is IPv6-enabled. See ip6(7P).

**FILES**

/etc/ftpd/ftpaccess	FTP Server configuration file
/etc/ftpd/ftpconversions	FTP Server conversions database
/etc/ftpd/ftpgroups	FTP Server enhanced group access file
/etc/ftpd/ftphosts	FTP Server individual user host access file
/etc/ftpd/ftpservers	FTP Server virtual hosting configuration file.
/etc/ftpd/ftpusers	File listing users for whom FTP login privileges are disallowed.
/etc/ftpusers	File listing users for whom FTP login privileges are disallowed. This use of this file is deprecated.
/var/log/xferlog	FTP Server transfer log file
/var/run/ftp.pids- <i>classname</i>	
/var/adm/wtmpx	Extended database files that contain the history of user access and accounting information for the wtmpx database.

**ATTRIBUTES** See attributes (5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWftpu

**SEE ALSO** csh(1), ftp(1), ftpcount(1), ftpwho(1), ls(1), ftpaddhost(1M), ftpconfig(1M), ftprestart(1M), ftpshut(1M), inetd(1M), syslogd(1M), chroot(2), umask(2), getpwent(3C), getusershell(3C), syslog(3C), ftpaccess(4), ftpconversions(4), ftpgroups(4), ftphosts(4), ftpservers(4), ftpusers(4), group(4), passwd(4), services(4), xferlog(4), wtmpx(4), attributes(5), ip6(7P)

in.ftpd(1M)

Allman, M., Ostermann, S., and Metz, C. *RFC 2428, FTP Extensions for IPv6 and NATs*. The Internet Society. September 1998.

Piscitello, D. *RFC 1639, FTP Operation Over Big Address Records (FOOBAR)*. Network Working Group. June 1994.

Postel, Jon, and Joyce Reynolds. *RFC 959, File Transfer Protocol (FTP)*. Network Information Center. October 1985.

St. Johns, Mike. *RFC 931, Authentication Server*. Network Working Group. January 1985.

**DIAGNOSTICS** `in.ftpd` logs various errors to `syslogd(1M)`, with a facility code of `daemon`.

**NOTES** The anonymous FTP account is inherently dangerous and should be avoided when possible.

The FTP Server must perform certain tasks as the superuser, for example, the creation of sockets with privileged port numbers. It maintains an effective user ID of the logged in user, reverting to the superuser only when necessary.

<b>NAME</b>	in.iked – daemon for the Internet Key Exchange (IKE)
<b>SYNOPSIS</b>	<pre> /usr/lib/inet/in.iked [-d] [-f filename] [-p level] /usr/lib/inet/in.iked -c [-f filename] </pre>
<b>DESCRIPTION</b>	<p>in.iked performs automated key management for IPsec using the Internet Key Exchange (IKE) protocol.</p> <p>in.iked implements the following:</p> <ul style="list-style-type: none"> <li>■ IKE authentication with either pre-shared keys, DSS signatures, RSA signatures, or RSA encryption.</li> <li>■ Diffie-Hellman key derivation using either 768, 1024, or 1536-bit public key moduli.</li> <li>■ Authentication protection with cipher choices of DES, Blowfish, or 3DES, and hash choices of either HMAC-MD5 or HMAC-SHA-1. Encryption in in.iked is limited to the IKE authentication and key exchange. See ipsecesp(7P) for information regarding IPsec protection choices.</li> </ul> <p>in.iked starts at boot time if the /etc/inet/ike/config file exists. See ike.config(4) for the format of this file.</p> <p>in.iked listens for incoming IKE requests from the network and for requests for outbound traffic using the PF_KEY socket. See pf_key(7P).</p> <p>in.iked has two support programs that are used for IKE administration and diagnosis: ikeadm(1M) and ikecert(1M).</p> <p>IKE only works for IPv4.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c                   Check the syntax of a configuration file.</li> <li>-d                   Use debug mode. The process stays attached to the controlling terminal and produces large amounts of debugging output.</li> <li>-f <i>filename</i>       Use <i>filename</i> instead of /etc/inet/ike/config. See ike.config(4) for the format of this file.</li> <li>-p <i>level</i>           Specify privilege level (<i>level</i>). This option sets how much ikeadm(1M) invocations can change or observe about the running in.iked.</li> </ul> <p>Valid <i>levels</i> are:</p> <ul style="list-style-type: none"> <li>0    Base level</li> <li>1    Access to preshared key info</li> <li>2    Access to keying material</li> </ul>

## in.iked(1M)

If `-p` is not specified, *level* defaults to 0.

**SECURITY** This program has sensitive private keying information in its image. Care should be taken with any core dumps or system dumps of a running `in.iked`- as these files contain sensitive keying information. Use the `coreadm(1M)` command to limit any corefiles produced by `in.iked`.

**FILES** `/etc/inet/ike/config`  
`/etc/inet/secret/ike.privatekeys/*`  
Private keys. A private key *must* have a matching public-key certificate with the same filename in `/etc/inet/ike/publickeys/`.  
`/etc/inet/ike/publickeys/*`  
Public-key certificates. The names are only important with regard to matching private key names.  
`/etc/inet/ike/crls/*`  
Public key certificate revocation lists.  
`/etc/inet/secret/ike.preshared`  
IKE pre-shared secrets for Phase I authentication.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

<b>NAME</b>	init, telinit – process control initialization								
<b>SYNOPSIS</b>	<pre><b>/sbin/init</b> [0123456abcQqSs] <b>/etc/telinit</b> [0123456abcQqSs]</pre>								
<b>DESCRIPTION</b>	init is a general process spawner. Its primary role is to create processes from information stored in the file <code>/etc/inittab</code> .								
<b>Run Level Defined</b>	At any given time, the system is in one of eight possible run levels. A run level is a software configuration under which only a selected group of processes exists. Processes spawned by <code>init</code> for each of these run levels are defined in <code>/etc/inittab</code> . <code>init</code> can be in one of eight run levels, 0–6 and S or s (S and s are identical). The run level changes when a privileged user runs <code>/sbin/init</code> . This sends appropriate signals to the original <code>init</code> spawned by the operating system at boot time, saying which run level to invoke.								
<b>init and System Booting</b>	<p>When the system is booted, <code>init</code> is invoked and the following occurs. First, it reads <code>/etc/default/init</code> to set environment variables. This is typically where TZ (time zone) and locale-related environments such as LANG or LC_CTYPE get set. (See the FILES section at the end of this page.) <code>init</code> then looks in <code>/etc/inittab</code> for the <code>initdefault</code> entry (see <code>inittab(4)</code>). If the <code>initdefault</code> entry:</p> <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">exists</td> <td><code>init</code> usually uses the run level specified in that entry as the initial run level to enter.</td> </tr> <tr> <td style="vertical-align: top;">does not exist</td> <td><code>/etc/inittab</code>, <code>init</code> asks the user to enter a run level from the system console.</td> </tr> <tr> <td style="vertical-align: top;">S or s</td> <td><code>init</code> goes to the single-user state. In this state, the system console device (<code>/dev/console</code>) is opened for reading and writing and the command <code>/sbin/su</code>, (see <code>su(1M)</code>), is invoked. Use either <code>init</code> or <code>telinit</code> to change the run level of the system. Note that if the shell is terminated (using an end-of-file), <code>init</code> only re-initializes to the single-user state if <code>/etc/inittab</code> does not exist.</td> </tr> <tr> <td style="vertical-align: top;">0–6</td> <td><code>init</code> enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run levels 2, 3, and 4 are available as multi-user operating states.</td> </tr> </table> <p>If this is the first time since power up that <code>init</code> has entered a run level other than single-user state, <code>init</code> first scans <code>/etc/inittab</code> for <code>boot</code> and <code>bootwait</code> entries (see <code>inittab(4)</code>). These entries are performed before any other processing of <code>/etc/inittab</code> takes place, providing that the run level entered matches that of the entry. In this way any special initialization of the operating system, such as mounting</p>	exists	<code>init</code> usually uses the run level specified in that entry as the initial run level to enter.	does not exist	<code>/etc/inittab</code> , <code>init</code> asks the user to enter a run level from the system console.	S or s	<code>init</code> goes to the single-user state. In this state, the system console device ( <code>/dev/console</code> ) is opened for reading and writing and the command <code>/sbin/su</code> , (see <code>su(1M)</code> ), is invoked. Use either <code>init</code> or <code>telinit</code> to change the run level of the system. Note that if the shell is terminated (using an end-of-file), <code>init</code> only re-initializes to the single-user state if <code>/etc/inittab</code> does not exist.	0–6	<code>init</code> enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run levels 2, 3, and 4 are available as multi-user operating states.
exists	<code>init</code> usually uses the run level specified in that entry as the initial run level to enter.								
does not exist	<code>/etc/inittab</code> , <code>init</code> asks the user to enter a run level from the system console.								
S or s	<code>init</code> goes to the single-user state. In this state, the system console device ( <code>/dev/console</code> ) is opened for reading and writing and the command <code>/sbin/su</code> , (see <code>su(1M)</code> ), is invoked. Use either <code>init</code> or <code>telinit</code> to change the run level of the system. Note that if the shell is terminated (using an end-of-file), <code>init</code> only re-initializes to the single-user state if <code>/etc/inittab</code> does not exist.								
0–6	<code>init</code> enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run levels 2, 3, and 4 are available as multi-user operating states.								

## init(1M)

	<p>file systems, can take place before users are allowed onto the system. <code>init</code> then scans <code>/etc/inittab</code> and executes all other entries that are to be processed for that run level.</p> <p>To spawn each process in <code>/etc/inittab</code>, <code>init</code> reads each entry and for each entry that should be respawned, it forks a child process. After it has spawned all of the processes specified by <code>/etc/inittab</code>, <code>init</code> waits for one of its descendant processes to die, a powerfail signal, or a signal from another <code>init</code> or <code>telinit</code> process to change the system's run level. When one of these conditions occurs, <code>init</code> re-examines <code>/etc/inittab</code>.</p>
<b>inittab Additions</b>	<p>New entries can be added to <code>/etc/inittab</code> at any time; however, <code>init</code> still waits for one of the above three conditions to occur before re-examining <code>/etc/inittab</code>. To get around this, <code>init Q</code> or <code>init q</code> command wakes <code>init</code> to re-examine <code>/etc/inittab</code> immediately.</p> <p>When <code>init</code> comes up at boot time and whenever the system changes from the single-user state to another run state, <code>init</code> sets the <code>ioctl(2)</code> states of the console to those modes saved in the file <code>/etc/ioctl.syscon</code>. <code>init</code> writes this file whenever the single-user state is entered.</p>
<b>Run Level Changes</b>	<p>When a run level change request is made, <code>init</code> sends the warning signal (<code>SIGTERM</code>) to all processes that are undefined in the target run level. <code>init</code> waits five seconds before forcibly terminating these processes by sending a kill signal (<code>SIGKILL</code>).</p> <p>When <code>init</code> receives a signal telling it that a process it spawned has died, it records the fact and the reason it died in <code>/var/adm/utmpx</code> and <code>/var/adm/wtmpx</code> if it exists (see <code>who(1)</code>). A history of the processes spawned is kept in <code>/var/adm/wtmpx</code>.</p> <p>If <code>init</code> receives a powerfail signal (<code>SIGPWR</code>) it scans <code>/etc/inittab</code> for special entries of the type <code>powerfail</code> and <code>powerwait</code>. These entries are invoked (if the run levels permit) before any further processing takes place. In this way <code>init</code> can perform various cleanup and recording functions during the powerdown of the operating system.</p>
<b>Environment Variables in /etc/defaults/init</b>	<p>You can set default values for environment variables, for such items as timezone and character formatting, in <code>/etc/default/init</code>. See the FILES section, below, for a list of these variables.</p>
<b>telinit</b>	<p><code>telinit</code>, which is linked to <code>/sbin/init</code>, is used to direct the actions of <code>init</code>. It takes a one-character argument and signals <code>init</code> to take the appropriate action.</p>
<b>SECURITY</b>	<p><code>init</code> uses <code>pam(3PAM)</code> for session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the session management module to be used for <code>init</code>. Here is a partial <code>pam.conf</code> file with entries for <code>init</code> using the UNIX session management module.</p> <pre>init session required /usr/lib/security/pam_unix.so.1</pre>

If there are no entries for the `init` service, then the entries for the "other" service will be used.

**OPTIONS**

- 0           Go into firmware.
- 1           Put the system in system administrator mode. All local file systems are mounted. Only a small set of essential kernel processes are left running. This mode is for administrative tasks such as installing optional utility packages. All files are accessible and no users are logged in on the system.
- 2           Put the system in multi-user mode. All multi-user environment terminal processes and daemons are spawned. This state is commonly referred to as the multi-user state.
- 3           Extend multi-user mode by making local resources available over the network.
- 4           Is available to be defined as an alternative multi-user environment configuration. It is not necessary for system operation and is usually not used.
- 5           Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible.
- 6           Stop the operating system and reboot to the state defined by the `initdefault` entry in `/etc/inittab`.
- a, b, c     process only those `/etc/inittab` entries having the a, b, or c run level set. These are pseudo-states, which may be defined to run certain commands, but which do not cause the current run level to change.
- Q, q       Re-examine `/etc/inittab`.
- S, s       Enter single-user mode. This is the only run level that doesn't require the existence of a properly formatted `/etc/inittab` file. If this file does not exist, then by default, the only legal run level that `init` can enter is the single-user mode. When in single-user mode, the filesystems required for basic system operation will be mounted. When the system comes down to single-user mode, these file systems will remain mounted (even if provided by a remote file server), and any other local filesystems will also be left mounted. During the transition down to single-user mode, all processes started by `init` or `init.d` scripts that should only be running in multi-user mode are killed. In addition, any process that has a `utmpx` entry will be killed. This last condition insures that all port monitors started by the SAC are killed and all services started by these port monitors, including `ttymon` login services, are killed.

**FILES**

`/dev/console`           System console device.

## init(1M)

<code>/etc/default/init</code>	Contains environment variables and their default values. For example, for the timezone variable, <code>TZ</code> , you might specify <code>TZ=US/Pacific</code> . The variables are:  <code>TZ</code> Either specifies the timezone information (see <code>ctime(3C)</code> ) or the name of a timezone information file <code>/usr/share/lib/zoneinfo</code> .  <code>CMASK</code> The mask (see <code>umask(1)</code> ) that <code>init</code> uses and that every process inherits from the <code>init</code> process. If not set, <code>init</code> uses the mask it inherits from the kernel. Note that <code>init</code> always attempts to apply a <code>umask</code> of <code>022</code> before creating a file, regardless of the setting of <code>CMASK</code> .  <code>LC_CTYPE</code> Character characterization information.  <code>LC_MESSAGES</code> Message translation.  <code>LC_MONETARY</code> Monetary formatting information.  <code>LC_NUMERIC</code> Numeric formatting information.  <code>LC_TIME</code> Time formatting information.  <code>LC_ALL</code> If set, all other <code>LC_*</code> environmental variables take-on this value.  <code>LANG</code> If <code>LC_ALL</code> is not set, and any particular <code>LC_*</code> is also not set, the value of <code>LANG</code> is used for that particular environmental variable.
<code>/etc/initpipe</code>	A named pipe used for internal communication.
<code>/etc/inittab</code>	Controls process dispatching by <code>init</code> .
<code>/etc/ioctl.syscon</code>	<code>ioctl</code> states of the console, as saved by <code>init</code> when single-user state is entered.
<code>/var/adm/utmpx</code>	User access and administration information.
<code>/var/adm/wtmpx</code>	History of user access and administration information.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

<b>SEE ALSO</b>	login(1), sh(1), stty(1), who(1), shutdown(1M), su(1M), ttymon(1M), ioctl(2), kill(2), ctime(3C), pam(3PAM), inittab(4), pam.conf(4), utmpx(4), attributes(5), pam_unix(5), termio(7I)
<b>DIAGNOSTICS</b>	If <code>init</code> finds that it is respawning an entry from <code>/etc/inittab</code> more than ten times in two minutes, assumes that there is an error in the command string in the entry, and generates an error message on the system console. It will then refuse to respawn this entry until either five minutes has elapsed or it receives a signal from a user-spawned <code>init</code> or <code>telinit</code> . This prevents <code>init</code> from eating up system resources when someone makes a typographical error in the <code>inittab</code> file, or a program is removed that is referenced in <code>/etc/inittab</code> .
<b>NOTES</b>	<p><code>init</code> and <code>telinit</code> can be run only by a privileged user.</p> <p>The <code>S</code> or <code>s</code> state must not be used indiscriminately in <code>/etc/inittab</code>. When modifying this file, it is best to avoid adding this state to any line other than <code>initdefault</code>.</p> <p>If a default state is not specified in the <code>initdefault</code> entry in <code>/etc/inittab</code>, state <code>6</code> is entered. Consequently, the system will loop by going to firmware and rebooting continuously.</p> <p>If the <code>utmpx</code> file cannot be created when booting the system, the system will boot to state <code>"s"</code> regardless of the state specified in the <code>initdefault</code> entry in <code>/etc/inittab</code>. This can occur if the <code>/var</code> file system is not accessible.</p> <p>When a system transitions down to the <code>S</code> or <code>s</code> state, the <code>/etc/nologin</code> file (see <code>nologin(4)</code>) is created. Upon subsequent transition to run level 2, this file is removed by a script in the <code>/etc/rc2.d</code> directory.</p> <p><code>init</code> uses <code>/etc/initpipe</code>, a named pipe, for internal communication.</p>

## init.wbem(1M)

<b>NAME</b>	init.wbem – start and stop the CIM Boot Manager
<b>SYNOPSIS</b>	<code>/etc/init.d/init.wbem start   stop   status</code>
<b>DESCRIPTION</b>	<p>The <code>init.wbem</code> utility is run automatically during installation and each time the system is rebooted. This utility manipulates the CIM Object Manager (CIMOM) and the Solaris Management Console (SMC) server, both of which run combined in a single process. <code>init.wbem</code> can be used to start, stop, or retrieve status from the server.</p>
<b>CIM Object Manager</b>	<p>The CIM Object Manager manages CIM objects on a WBEM-enabled system. A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects are stored internally as Java classes.</p> <p>When a WBEM client application accesses information about a CIM object, the CIM Object Manager contacts either the appropriate provider for that object or the CIM Object Manager Repository. Providers are classes that communicate with managed objects to access data.</p> <p>When a WBEM client application requests data from a managed resource that is not available from the CIM Object Manager Repository, the CIM Object Manager forwards the request to the provider for that managed resource. The provider dynamically retrieves the information.</p> <p>At startup, the CIM Object Manager performs the following functions:</p> <ul style="list-style-type: none"><li>■ Listens for RMI connections on RMI port 5987 and for XML/HTTP connections on HTTP port 5988.</li><li>■ Sets up a connection to the CIM Object Manager Repository.</li><li>■ Waits for incoming requests.</li></ul> <p>During normal operations, the CIM Object Manager performs the following functions:</p> <ul style="list-style-type: none"><li>■ Performs security checks to authenticate user login and authorization to access namespaces.</li><li>■ Performs syntactical and semantic checking of CIM data operations to ensure that they comply with the latest CIM Specification.</li><li>■ Routes requests to the appropriate provider or to the CIM Object Manager Repository.</li><li>■ Delivers data from providers and from the CIM Object Manager Repository to WBEM client applications.</li></ul> <p>A WBEM client application contacts the CIM Object Manager to establish a connection when it needs to perform WBEM operations, such as creating a CIM class or updating a CIM instance. When a WBEM client application connects to a CIM Object Manager, it gets a reference to the CIM Object Manager, which it then uses to request services and operations.</p>

init.wbem(1M)

**Solaris Management Console Server**

The SMC server is the back end to the front end console, *smc(1M)*. It provides tools for the console to download and performs common services for the console and its tools to use, such as authentication, authorization, logging, messaging, and persistence.

**System Booting**

The *init.wbem* script is installed in the */etc/init.d* directory. A link to it exists in */etc/rc2.d/S90wbem*, which is run with the *start* option when init state 2 is entered (normally at boot time). Other links to it exist in */etc/rc0.d/K36wbem*, */etc/rc1.d/K36wbem*, and */etc/rcS.d/K36wbem*, which are run with the *stop* option when init states 0, 1, and S are entered (normally at system halt, or when entering “system administrator mode” or single user mode).

**OPTIONS**

The following options are supported:

- start*                    Starts the CIMOM and SMC server on the local host.
- stop*                    Stops the CIMOM and SMC server on the local host.
- status*                 Gets the status of the CIMOM and SMC server on the local host.

**NOTES**

When the *init.wbem* script is run, it does not run the CIMOM and SMC server directly. The server process is in Java and is too heavyweight to be run immediately at system boot time. Instead, a lightweight process is run which listens on the ports the CIMOM and the SMC server normally use, running the two servers the first time it gets a connection on either port, thus acting similarly to *inetd(1M)*.

Because Java programs cannot inherit file descriptors as other programs can, there is a small time period from when the first connection is made until the server is fully operational where client connections may be dropped. WBEM clients are immune to this, as they will retry until the server come online. SMC clients are not immune, and it may be necessary to manually reconnect, though this should not happen in the common case.

## in.lpd(1M)

<b>NAME</b>	in.lpd – BSD print protocol adaptor				
<b>SYNOPSIS</b>	<code>/usr/lib/print/in.lpd</code>				
<b>DESCRIPTION</b>	<p>in.lpd implements the network listening service for the BSD print protocol specified in RFC 1179. The BSD print protocol provides a remote interface for systems to interact with a local spooling system. The protocol defines five standard requests from the client to the server: starting queue processing, transferring print jobs, retrieving terse status, retrieving verbose status, and canceling print jobs.</p> <p>in.lpd is started from inetd (see inetd(1M)). inetd waits for connections on TCP port 515. Upon receipt of a connect request, in.lpd is started to service the connection. Once the request has been filled, in.lpd closes the connection and exits.</p>				
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <table><tr><td>0</td><td>Successful completion.</td></tr><tr><td>non-zero</td><td>An error occurred.</td></tr></table>	0	Successful completion.	non-zero	An error occurred.
0	Successful completion.				
non-zero	An error occurred.				
<b>FILES</b>	<p><code>/etc/printers.conf</code> System printer configuration database.</p> <p><code>printers.conf.byname</code> NIS version of <code>/etc/printers.conf</code>.</p> <p><code>fns.ctx_dir.domain</code> NIS+ version of <code>/etc/printers.conf</code>.</p> <p><code>/usr/lib/print/bsd-adaptor/bsd_*.so*</code> Spooler translation modules.</p>

<b>NAME</b>	in.mpathd – daemon for network adapter (NIC) failure detection, recovery, automatic failover and failback
<b>SYNOPSIS</b>	<code>/sbin/in.mpathd</code>
<b>DESCRIPTION</b>	<p>The <code>in.mpathd</code> daemon performs Network Interface Card (NIC) failure and repair detection. In the event of a NIC failure, it causes IP network access from the failed NIC to failover to a standby NIC, if available, or to any another operational NIC that has been configured as part of the same network multipathing group. Once the failed NIC is repaired, all network access will be restored to the repaired NIC.</p> <p><code>in.mpathd</code> needs a special test address on each NIC for the purpose of sending and receiving probes on each NIC. Use the <code>ifconfig</code> command <code>-failover</code> option to configure these test addresses. See <code>ifconfig(1M)</code>. The test address must belong to a subnet that is known to the hosts and routers on the link.</p> <p>The <code>in.mpathd</code> daemon can detect NIC failure and repair by two methods, by sending and receiving ICMP echo requests and replies on each NIC, and by monitoring the <code>IFF_RUNNING</code> flag for each NIC. The link state on some models of NIC is indicated by the <code>IFF_RUNNING</code> flag, allowing for faster failure detection when the link goes down. The <code>in.mpathd</code> daemon considers a NIC to have failed if either of the above two methods indicates failure. A NIC is considered to be repaired only if both methods indicate the NIC is repaired.</p> <p>The <code>in.mpathd</code> daemon sends the ICMP echo request probes to on-link routers. If no routers are available, it sends the probes to neighboring hosts. Thus, for network failure detection and repair, there must be at least one neighbor on each link that responds to ICMP echo request probes.</p> <p><code>in.mpathd</code> works on both IPv4 and IPv6. If IPv4 is plumbed on a NIC, an IPv4 test address is configured on the NIC, and the NIC is configured as part of a network multipathing group, then <code>in.mpathd</code> will start sending ICMP probes on the NIC using IPv4.</p> <p>In the case of IPv6, the link-local address must be configured as the test address. The <code>in.mpathd</code> daemon will not accept a non-link-local address as a test address. If the NIC is part of a multipathing group, and the test address has been configured, then <code>in.mpathd</code> will probe the NIC for failures using IPv6.</p> <p>Even if both the IPv4 and IPv6 protocol streams are plumbed, it is sufficient to configure only one of the two, that is, either an IPv4 test address or an IPv6 test address on a NIC. If only an IPv4 test address is configured, it probes using only ICMPv4. If only an IPv6 test address is configured, it probes using only ICMPv6. If both type test addresses are configured, it probes using both ICMPv4 and ICMPv6.</p> <p>The <code>in.mpathd</code> daemon accesses three variable values in <code>/etc/default/mpathd</code>: <code>FAILURE_DETECTION_TIME</code>, <code>FAILBACK</code> and <code>TRACK_INTERFACES_ONLY_WITH_GROUPS</code>.</p>

## in.mpathd(1M)

The `FAILURE_DETECTION_TIME` variable specifies the NIC failure detection time for the ICMP echo request probe method of detecting NIC failure. The shorter the failure detection time, the greater the volume of probe traffic. The default value of `FAILURE_DETECTION_TIME` is 10 seconds. This means that NIC failure will be detected by `in.mpathd` within 10 seconds. NIC failures detected by the `IFF_RUNNING` flag being cleared are acted on as soon as the `in.mpathd` daemon notices the change in the flag. The NIC repair detection time cannot be configured; however, it is defined as double the value of `FAILURE_DETECTION_TIME`.

By default, `in.mpathd` does failure detection only on NICs that are configured as part of a multipathing group. You can set `TRACK_INTERFACES_ONLY_WITH_GROUPS` to `no` to enable failure detection by `in.mpathd` on all NICs, even if they are not part of a multipathing group. However, `in.mpathd` cannot do failover from a failed NIC if it is not part of a multipathing group.

The `in.mpathd` daemon will restore network traffic back to the previously failed NIC, after it has detected a NIC repair. To disable this, set the value of `FAILBACK` to `no` in `/etc/default/mpathd`.

**FILES** `/etc/default/mpathd` Contains default values used by the `in.mpathd` daemon.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr

**SEE ALSO** `ifconfig(1M)`, `attributes(5)`, `icmp(7P)`, `icmp6(7P)`,

*System Administration Guide, Volume 3*

**DIAGNOSTICS** `IFF_NOFAILOVER` address  
*address* is not unique and failure detection is not possible  
Every test address that is configured must be unique on the system. Otherwise `in.mpathd` cannot do failure detection. Since the IPv6 test address is a link-local address, which in turn is derived from the ethernet address, each NIC must have a unique MAC address.

NIC *interface\_name* of group *group\_name* is not plumbed for IPv[4|6] and may affect failover capability

All NICs in a multipathing group must be homogeneously plumbed. For example, if a NIC is plumbed for IPv4, then all NICs in the group must be plumbed for IPv4. The streams modules pushed on all NICs must be identical.

Failures cannot be detected on *interface\_name* as no `IFF_NOFAILOVER` address is available

Every NIC that is configured as part of a multipathing group must have a test address, which can be either IPv4 or IPv6, or both. Otherwise `in.mpathd` cannot probe the NIC, and this message is displayed.

Invalid failure detection *time* assuming default 10000

An invalid value was encountered for `FAILURE_DETECTION_TIME` in the `/etc/default/mpathd` file.

Too small failure detection time of *time* assuming minimum 100

The minimum value that can be specified for `FAILURE_DETECTION_TIME` is currently 100 milliseconds.

Invalid value for `FAILBACK` *value*

Valid values for the boolean variable `FAILBACK` are `yes` or `no`.

Invalid value for `TRACK_INTERFACES_ONLY_WITH_GROUPS` *value*

Valid values for the boolean variable `TRACK_INTERFACES_ONLY_WITH_GROUPS` are `yes` or `no`.

Cannot meet requested failure detection time of *time* ms on (inet[4|6] *interface\_name*)

new failure detection is *time* ms

The round trip time for ICMP probes is higher than the specified failure detection time. The network is probably congested or the probe targets are loaded.

`in.mpathd` automatically increases the failure detection time to whatever it can achieve under these conditions.

Improved failure detection time *time* ms

The round trip time for ICMP probes has now decreased and `in.mpathd` has lowered the failure detection time correspondingly.

NIC failure detected on *interface\_name*

`in.mpathd` has detected NIC failure on *interface\_name*, and has set the `IFF_FAILED` flag on NIC *interface\_name*.

Successfully failed over from NIC *interface\_name1* to NIC *interface\_name2*

`in.mpathd` has caused the network traffic to failover from NIC *interface\_name1* to NIC *interface\_name2*, which is part of the multipathing group.

NIC repair detected on *interface\_name*

`in.mpathd` has detected that NIC *interface\_name* is repaired and operational. If the `IFF_FAILED` flag on the NIC was previously set, it will be reset..

Successfully failed back to NIC *interface\_name*

`in.mpathd` has restored network traffic back to NIC *interface\_name*, which is now repaired and operational.

The link has gone down on *interface\_name*

`in.mpathd` has detected that the `IFF_RUNNING` flag for NIC *interface\_name* has been cleared, indicating the link has gone down.

in.mpathd(1M)

The link has come up on *interface\_name*

`in.mpathd` has detected that the `IFF_RUNNING` flag for NIC *interface\_name* has been set, indicating the link has come up.

<b>NAME</b>	in.named, named – Internet domain name server (DNS)
<b>SYNOPSIS</b>	<b>in.named</b> [-d <i>debuglevel</i> ] [-p <i>port#</i> ] [ [-b   -c] <i>config_file</i> ] [-fqr] [-u <i>user_name</i> ] [-g <i>group_name</i> ] [-t <i>directory</i> ] [-w <i>directory</i> ] [ <i>config_file</i> ]
<b>DESCRIPTION</b>	<p>in.named is the Internet domain name server. For more information on the Internet name-domain system, see <i>RFC 1033</i>, <i>RFC 1034</i> and <i>RFC 1035</i>.</p> <p>When run without any arguments, in.named reads the default configuration file /etc/named.conf, reads any initial data, and listens for queries. If you give a <i>config_file</i> argument at the end of the command line, it will override any <i>config_file</i> that you specified by using the -b or -c options.</p> <p>The named.conf(4) configuration file controls some of the options and behavior for in.named.</p>
<b>OPTIONS</b>	<p>in.named supports the following options:</p> <p>-b   c <i>configfile</i>                      Use an alternative configuration file. The default value for <i>configfile</i> is /etc/named.conf. The <i>configfile</i>, if any, specified at the end of the command line, overrides any value specified by this argument.</p> <p>-d <i>debuglevel</i>                          Print debugging information. The value of <i>debuglevel</i> determines the level of messages to print. If negative, <i>debuglevel</i> is set to 1.</p> <p>                                            The new debugging framework is considerably more sophisticated than in previous versions of in.named. The logging statement in the configuration file allows for multiple, distinct levels of debugging for each of a large set of categories of events, for example, for queries and transfers in and out. See named.conf(4).</p> <p>-f                                          Run this process in the foreground. The process will not fork(2). By default, in.named runs as a daemon in the background.</p> <p>-g <i>group_name</i>                          Specify the group the server should run as after it initializes. The value specified may be either a group name or a numeric group id.</p> <p>-p <i>port#</i>                                Use the specified remote port number. in.named will send queries to this port number. By default, the value is the standard port number, that is, the port number returned by getservbyname(3SOCKET) for the service domain.</p> <p>                                            The in.named command previously supported the syntax:</p> <p>                                            -p <i>port#[/localport#]</i> where <i>port#</i> was the first port used</p>

## in.named(1M)

	when contacting remote servers and <i>localport#</i> was the service port bound by the local instance of <i>in.named</i> .
	The current usage is equivalent to the old usage without <i>localport#</i> specified. This functionality can be specified with the <i>listen-on</i> clause options statement in the configuration file.
-q	Trace all incoming queries. This option is deprecated in favor of the <i>queries</i> logging category of the logging statement in <i>named.conf</i> . See <i>named.conf</i> (4).
-r	Turn recursion off in the server. Responses come only from local (primary or secondary) zones. You can use this option on root servers. By default, the server uses recursion. This option is deprecated and is overridden by the <i>recursion</i> clause of the <i>options</i> statement in the configuration file.
-t <i>directory</i>	Specify the directory that the server is to <i>chroot</i> (2) into when it finishes processing command line arguments.
-u <i>user_name</i>	Specify the user that the server should run as after it initializes. The value of <i>user_name</i> may be either a user name or a numeric user id. If the <i>-g</i> option is not invoked, then the group id will be the primary group of the user specified. Since <i>initgroups</i> (3C) is called, all of the user's group will be available to the server.
-v	Report the version and exit.
-w <i>directory</i>	Set the working directory of the server. The <i>directory</i> clause of the <i>options</i> statement overrides any value specified on the command line. The default working directory is the current directory (".").

For compatibility with older implementations any additional argument will be interpreted as the name of the configuration file. This argument overrides any *config\_file* specified by means of the *-b* or *-c* options. If no further argument is given, then the default configuration file, */etc/named.conf* is used.

### Master File Format

The master file consists of control information and a list of resources for objects in the zone. The file has the following form:

```
$INCLUDE <filename><opt_domain>
$ORIGIN <domain>
$TTL <ttd>
<domain><opt_ttd><opt_class><type><resource_record_data>
```

The fields are defined as follows:

<i>domain</i>	The value of <i>domain</i> can be "." for root, "@" for the current origin, or a standard domain name. If <i>domain</i> is a standard domain name that does not end with ".", the current origin is appended to the domain. Domain names ending with "." are not modified.
<i>opt_domain</i>	This field is used to define an origin for the data in an included file. It is equivalent to placing an \$ORIGIN statement before the first line of the included file. This field is optional. Neither the <i>opt_domain</i> field nor \$ORIGIN statements in the included file modify the current origin for this file.
<i>tll</i>	An integer number that sets the default time-to-live for future records that do not have an explicit <i>tll</i> .
<i>opt_ttl</i>	An optional integer number for the time-to-live field. If not set the <i>tll</i> is taken from the last \$TTL statement. If no \$TTL statement has occurred then the SOA minimum value is used, and a warning is generated.
<i>opt_class</i>	The object address type. Currently only one type is supported, IN, for objects connected to the DARPA Internet.
<i>type</i>	<p>This field contains one of the following tokens. The data expected in the <i>resource_record_data</i> field is in parentheses:</p> <p>A           A host address (dotted-quad IP address).</p> <p>NS           An authoritative name server (domain).</p> <p>MX           A mail exchanger (domain), preceded by a preference value (0..32767), with lower numeric values representing higher logical preferences.</p> <p>CNAME       The canonical name for an alias (domain).</p> <p>SOA          Marks the start of a zone of authority (domain of originating host, domain address of maintainer, a serial number and the following parameters in seconds: refresh, retry, expire and minimum <i>tll</i>). See <i>RFC 883</i> and <i>RFC 2308</i>.</p> <p>NULL        A NULL resource record (no format or data).</p> <p>RP           A Responsible Person for some domain name (mailbox, TXT-referral).</p> <p>PTR          A domain name pointer (domain).</p>

## in.named(1M)

	<code>HINFO</code>	Host information ( <code>cpu_type</code> , <code>OS_type</code> ).
	<code>resource_record_data</code>	Resource records normally end at the end of a line, but may be continued across lines between opening and closing parentheses. Comments are introduced by semicolons and continue to the end of the line.  There are other resource record types not shown here. Some resource record types may have been standardized in more recent RFCs, but they have not yet been implemented in this version of BIND
<b>SOA Record Format</b>	Each master zone file should begin with an SOA record for the zone. An example SOA record is as follows:	
	<pre>@      IN      SOA      ucbvax.Berkeley.EDU.  rwh.ucbvax.Berkeley.EDU.  (                                 1989020501      ; serial                                 10800      ; refresh                                 3600      ; retry                                 3600000   ; expire                                 86400    ) ; minimum</pre>	
	The SOA specifies a serial number that should be incremented each time the master file is changed. Note that the serial number can be given as a dotted number, but this is a very unwise thing to do since the translation to normal integers is by means of concatenation rather than multiplication and addition. You can spell out the year, month, day of month, and 0..99 version number and still fit inside the unsigned 32-bit size of this field. (It's true that we will have to rethink this strategy in the year 4294, but we're not worried about it.)	
	Secondary servers check the serial number at intervals specified by the refresh time in seconds; if the serial number changes, a zone transfer will be done to load the new data. If a master server cannot be contacted when a refresh is due, the retry time specifies the interval at which refreshes should be attempted. If a master server cannot be contacted within the interval given by the expire time, all data from the zone is discarded by secondary servers. The minimum value is the cache time-to-live for negative answers. See <i>RFC 2308</i> .	
<b>FILES</b>	<code>/etc/named.conf</code>	default name server configuration file.
	<code>/var/run/named.pid</code>	the process ID.
	<code>srvcwd</code>	<code>in.named</code> 's current working directory, usually set by the "directory" options statement in <code>named.conf</code> .
	<code>srvcwd/named_dump.db</code>	dump of the name server database.
	<code>srvcwd/named.run</code>	debug output.
	<code>srvcwd/named.stats</code>	name server statistics data.
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:	

in.named(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWinamd
Interface Stability	Standard BIND 8.2.4

Vixie, Paul, Dunlap, Kevin J., Karels, Michael J., *Name Server Operations Guide for BIND*. Internet Software Consortium. 1996.

**NOTES**

The boot file directives `domain` and `suffixes` are now obsolete. They have been replaced by a resolver-based implementation of suffixing for partially-qualified domain names. The earlier mechanisms failed under a number of situations, for example, when the local name server did not have complete information.

The following signals have the specified effect when sent to the server process using the `kill(1)` command:

**SIGHUP** Causes the server to read `named.conf` and reload the database. SIGHUP will also cause the server to check the serial number on all secondary zones.

## in.named(1M)

SIGINT	Dumps the current database and cache to <code>named_dump.db</code> .
SIGILL	Dumps statistics data into <code>named.stats</code> . Statistics data is appended to the file.
SIGTERM	Saves any modified dynamic zones to the file system and shuts down the server.
SIGUSR1	Turns on debugging. Each additional SIGUSR1 signal increments the debug level.
SIGUSR2	Turns off debugging completely.
SIGWINCH	Toggles logging of all incoming queries by means of <code>syslog(3C)</code> .

<b>NAME</b>	in.ndpd – daemon for IPv6 autoconfiguration
<b>SYNOPSIS</b>	<code>/usr/sbin/in.ndpd [-adt] [-f <i>config_file</i>]</code>
<b>DESCRIPTION</b>	<p>in.ndpd provides both the host and router autoconfiguration components of Neighbor Discovery for IPv6 and Stateless Address Autoconfiguration for IPv6. In particular, in.ndpd implements</p> <ul style="list-style-type: none"> <li>■ router discovery;</li> <li>■ prefix discovery;</li> <li>■ parameter discovery; and</li> <li>■ address autoconfiguration.</li> </ul> <p>Other aspects of Neighbor Discovery are implemented by ip6(7P), including:</p> <ul style="list-style-type: none"> <li>■ address resolution;</li> <li>■ neighbor unreachability detection; and</li> <li>■ redirect.</li> </ul> <p>The duplicate address detection function is implemented by ifconfig(1M).</p> <p>If the <code>/etc/inet/ndpd.conf</code> file does not exist or does not set the variable <code>AdvSendAdvertisements</code> to true for a network interface, then in.ndpd will make the node a host for that interface, that is, sending router solicitation messages and then using router advertisement messages it receives to autoconfigure the node. Note that in.ndpd only autoconfigures the addresses of global or site-local scope from the prefix advertisement.</p> <p>If <code>AdvSendAdvertisements</code> is set to true for an interface, then in.ndpd will perform router functions on that interface, that is, sending router advertisement messages to autoconfigure the attached hosts, but not use any advertisements it receives for autoconfiguration. However, when sending advertisements, in.ndpd will use the advertisements it sends itself to autoconfigure its prefixes. For improved robustness in.ndpd stores any autoconfigured IPv6 addresses and their expiration times in state files named <code>ndpd_state.interface</code> that are located in the <code>/var/inet</code> directory. Should in.ndpd fail to find any routers, it will use the state files as a fallback, autoconfiguring those addresses if the recorded addresses have remaining lifetime. This ensures that a host that reboots faster than the routers, for example after a short power failure, will continue using the addresses that it had before the power failure.</p>
<b>OPTIONS</b>	<p>-a Turn off stateless address auto configuration. When set, the daemon does not autoconfigure any addresses and does not renumber any addresses.</p> <p>-d Turn on large amounts of debugging output on <code>stdout</code>. When set, the program runs in the foreground and stays attached to the controlling terminal.</p> <p>-f <i>config_file</i> Use <i>config_file</i> for configuration information instead of the default <code>/etc/inet/ndpd.conf</code>.</p>

## in.ndpd(1M)

-t Turn on tracing (printing) of all sent and received packets  
tostdout. When set, the program runs in the foreground and  
stays attached to the controlling terminal.

**FILES** /etc/inet/ndpd.conf Configuration file. Not needed on a host but  
required on a router to enable in.ndpd to  
advertise autoconfiguration information to  
the hosts.

/var/inet/ndpd\_state.interface Contains the addresses for *interface*. The  
existence of an address in this file does not  
imply that the address is usable, since the  
address lifetime may have expired.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWroute

**SEE ALSO** ifconfig(1M), ndpd.conf(4), attributes(5), icmp6(7p), ip6(7p) attributes(5)

Thomson, S., Narten, T., *RFC 2462, IPv6 Stateless Address Autoconfiguration*, The Internet Society, December 1998.

**DIAGNOSTICS** Receipt of a SIGHUP signal will make in.ndpd restart and reread  
/etc/inet/ndpd.conf.

<b>NAME</b>	in.rarpd, rarpd – DARPA Reverse Address Resolution Protocol server
<b>SYNOPSIS</b>	<pre>/usr/sbin/in.rarpd [-d] -a /usr/sbin/in.rarpd [-d] device unit</pre>
<b>DESCRIPTION</b>	<p>in.rarpd starts a daemon that responds to Reverse Address Resolution Protocol (RARP) requests. The daemon forks a copy of itself that runs in background. It must be run as root.</p> <p>RARP is used by machines at boot time to discover their Internet Protocol (IP) address. The booting machine provides its Ethernet address in a RARP request message. Using the <code>ethers</code> and <code>hosts</code> databases, <code>in.rarpd</code> maps this Ethernet address into the corresponding IP address which it returns to the booting machine in an RARP reply message. The booting machine must be listed in both databases for <code>in.rarpd</code> to locate its IP address. <code>in.rarpd</code> issues no reply when it fails to locate an IP address.</p> <p><code>in.rarpd</code> uses the STREAMS-based Data Link Provider Interface (DLPI) message set to communicate directly with the datalink device driver.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a        Get the list of available network interfaces from IP using the SIOCGIFADDR ioctl and start a RARP daemon process on each interface returned.</li> <li>-d        Print assorted debugging messages while executing.</li> </ul>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Starting An <code>in.rarpd</code> Daemon For Each Network Interface Name Returned From <code>/dev/ip</code>:</p> <p>The following command starts an <code>in.rarpd</code> for each network interface name returned from <code>/dev/ip</code>:</p> <pre>example# /usr/sbin/in.rarpd -a</pre> <p><b>EXAMPLE 2</b> Starting An <code>in.rarpd</code> Daemon On The Device <code>/dev/le</code> With The Device Instance Number 0</p> <p>The following command starts one <code>in.rarpd</code> on the device <code>/dev/le</code> with the device instance number 0.</p> <pre>example# /usr/sbin/in.rarpd le 0</pre>
<b>FILES</b>	<pre>/etc/ethers     File or other source, as specified by nsswitch.conf(4). /etc/hosts      File or other source, as specified by nsswitch.conf(4).</pre>

<b>NAME</b>	in.rdisc, rdisc – network router discovery daemon
<b>SYNOPSIS</b>	<pre> /usr/sbin/in.rdisc [-a] [-f] [-s] [send-address] [receive-address]  /usr/sbin/in.rdisc -r [-p preference] [-T interval] [send-address] [receive-address] </pre>
<b>DESCRIPTION</b>	<p>in.rdisc implements the ICMP router discovery protocol. The first form of the command is used on hosts and the second form is used on routers.</p> <p>At boot time, in.rdisc is invoked in either the first form (host mode) or second form (router mode). The second form is invoked under the following conditions:</p> <ul style="list-style-type: none"> <li>■ A machine has multiple interfaces</li> <li>■ The interfaces are not configured by DHCP</li> <li>■ The defaultrouter(4) and /etc/notrouter files are not present</li> </ul> <p>Otherwise, the first form of in.rdisc is invoked.</p> <p>On a host, in.rdisc populates the network routing tables with default routes. On a router, advertises the router to all the hosts.</p> <p><b>Host (First Form)</b> On a host, in.rdisc listens on the ALL_HOSTS (224.0.0.1) multicast address for ROUTER_ADVERTISE messages from routers. The received messages are handled by first ignoring those listed router addresses with which the host does not share a network. Among the remaining addresses, the ones with the highest preference are selected as default routers and a default route is entered in the kernel routing table for each one of them.</p> <p>Optionally, in.rdisc can avoid waiting for routers to announce themselves by sending out a few ROUTER_SOLICITATION messages to the ALL_ROUTERS (224.0.0.2) multicast address when it is started.</p> <p>A timer is associated with each router address. The address will no longer be considered for inclusion in the routing tables if the timer expires before a new <i>advertise</i> message is received from the router. The address will also be excluded from consideration if the host receives an <i>advertise</i> message with the preference being maximally negative or with a lifetime of zero.</p> <p><b>Router (Second Form)</b> When in.rdisc is started on a router, it uses the SIOCGIFCONF ioctl(2) to find the interfaces configured into the system and it starts listening on the ALL_ROUTERS multicast address on all the interfaces that support multicast. It sends out <i>advertise</i> messages to the ALL_HOSTS multicast address advertising all its IP addresses. A few initial <i>advertise</i> messages are sent out during the first 30 seconds and after that it will transmit <i>advertise</i> messages approximately every 600 seconds.</p> <p>When in.rdisc receives a <i>solicitation</i> message, it sends an <i>advertise</i> message to the host that sent the <i>solicitation</i> message.</p> <p>When in.rdisc is terminated by a signal, it sends out an <i>advertise</i> message with the preference being maximally negative.</p>

## in.rdisc(1M)

### OPTIONS

- a Accept all routers independent of the preference they have in their *advertise* messages. Normally, *in.rdisc* only accepts (and enters in the kernel routing tables) the router or routers with the highest preference.
- f Run *in.rdisc* forever even if no routers are found. Normally, *in.rdisc* gives up if it has not received any *advertise* message after soliciting three times, in which case it exits with a non-zero exit code. If *-f* is not specified in the first form then *-s* must be specified.
- r Act as a router, rather than a host.
- s Send three *solicitation* messages initially to quickly discover the routers when the system is booted. When *-s* is specified, *in.rdisc* exits with a non-zero exit code if it can not find any routers. This can be overridden with the *-f* option.
- p *preference* Set the preference transmitted in the *solicitation* messages. The default is zero.
- T *interval* Set the interval between transmitting the *advertise* messages. The default time is 600 seconds.

### FILES

*/etc/notrouter* A file that acts as a flag for a boot-time script that determines whether a machine will act as a router or a host. The presence of the *notrouter* file prevents a machine that does not have a default route from acting as an IPv4 router, even if that machine has multiple interfaces.

<b>NAME</b>	in.rexecd, rexecd – remote execution server				
<b>SYNOPSIS</b>	<b>in.rexecd</b>				
<b>DESCRIPTION</b>	<p><code>in.rexecd</code> is the server for the <code>rexec(3SOCKET)</code> routine. The server provides remote execution facilities with authentication based on user names and passwords. It is invoked automatically as needed by <code>inetd(1M)</code>, and then executes the following protocol:</p> <ol style="list-style-type: none"> <li>1. The server reads characters from the socket up to a null (<code>\0</code>) byte. The resultant string is interpreted as an ASCII number, base 10.</li> <li>2. If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the <code>stderr</code>. A second connection is then created to the specified port on the client's machine.</li> <li>3. A null terminated user name of at most 16 characters is retrieved on the initial socket.</li> <li>4. A null terminated password of at most 16 characters is retrieved on the initial socket.</li> <li>5. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.</li> <li>6. <code>rexecd</code> then validates the user as is done at login time and, if the authentication was successful, changes to the user's home directory, and establishes the user and group protections of the user. If any of these steps fail the connection is aborted and a diagnostic message is returned.</li> <li>7. A null byte is returned on the connection associated with the <code>stderr</code> and the command line is passed to the normal login shell of the user. The shell inherits the network connections established by <code>rexecd</code>.</li> </ol>				
<b>USAGE</b>	<code>in.rexecd</code> and <code>rexecd</code> are IPv6-enabled. See <code>ip6(7P)</code> .				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWrcmds</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmds
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWrcmds				
<b>SEE ALSO</b>	<code>inetd(1M)</code> , <code>rexec(3SOCKET)</code> , <code>inetd.conf(4)</code> , <code>attributes(5)</code> , <code>ip6(7P)</code>				
<b>DIAGNOSTICS</b>	<p>All diagnostic messages are returned on the connection associated with the <code>stderr</code>, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 (0 is returned in step 7 above upon successful completion of all the steps prior to the command execution).</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>username too long</code></td> <td>The name is longer than 16 characters.</td> </tr> <tr> <td><code>password too long</code></td> <td>The password is longer than 16 characters.</td> </tr> </table>	<code>username too long</code>	The name is longer than 16 characters.	<code>password too long</code>	The password is longer than 16 characters.
<code>username too long</code>	The name is longer than 16 characters.				
<code>password too long</code>	The password is longer than 16 characters.				

in.rexecd(1M)

command too long	The command line passed exceeds the size of the argument list (as configured into the system).
Login incorrect.	No password file entry for the user name existed.
Password incorrect.	The wrong password was supplied.
No remote directory.	The <code>chdir</code> command to the home directory failed.
Try again.	A fork by the server failed.
/usr/bin/sh: ...	The user's login shell could not be started.

<b>NAME</b>	in.ripngd – network routing daemon for IPv6
<b>SYNOPSIS</b>	<code>/usr/sbin/in.ripngd [-s] [-q] [-t] [-p n] [-P] [-v ] [logfile]</code>
<b>DESCRIPTION</b>	<p>in.ripngd is the IPv6 equivalent of in.routed(1M). It is invoked at boot time to manage the network routing tables. The routing daemon uses the Routing Information Protocol for IPv6.</p> <p>In normal operation, in.ripngd listens on the udp(7P) socket port 521 for routing information packets. If the host is an internetwork router, it periodically supplies copies of its routing tables to any directly connected hosts and networks.</p> <p>When in.ripngd is started, it uses the SIOCGLIFCONF ioctl(2) to find those directly connected IPv6 interfaces configured into the system and marked "up"; the software loopback interface is ignored. If multiple interfaces are present, it is assumed the host will forward packets between networks. in.ripngd then multicasts a request packet on each IPv6 interface and enters a loop, listening for request and response packets from other hosts.</p> <p>When a request packet is received, in.ripngd formulates a reply based on the information maintained in its internal tables. The response packet contains a list of known routes. With each route is a number specifying the number of bits in the prefix. The prefix is the number of bits in the high order part of an address that indicate the subnet or network that the route describes. Each route reported also has a "hop count" metric. A count of 16 or greater is considered "infinity." The metric associated with each route returned provides a metric relative to the sender.</p> <p>The request packets received by in.ripngd are used to update the routing tables if one of the following conditions is satisfied:</p> <ul style="list-style-type: none"> <li>■ No routing table entry exists for the destination network or host, and the metric indicates the destination is "reachable, that is, the hop count is not infinite.</li> <li>■ The source host of the packet is the same as the router in the existing routing table entry. That is, updated information is being received from the very internetwork router through which packets for the destination are being routed.</li> <li>■ The existing entry in the routing table has not been updated for a period of time, defined to be 90 seconds, and the route is at least as cost-effective as the current route.</li> <li>■ The new route describes a shorter route to the destination than the one currently stored in the routing tables; this is determined by comparing the metric of the new route against the one stored in the table.</li> </ul> <p>When an update is applied, in.ripngd records the change in its internal tables and generates a response packet to all directly connected hosts and networks. To allow possible unstable situations to settle, in.ripngd waits a short period of time (no more than 30 seconds) before modifying the kernel's routing tables.</p>

## in.ripngd(1M)

In addition to processing incoming packets, `in.ripngd` also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed an additional 60 seconds to insure the invalidation is propagated throughout the internet.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks.

**OPTIONS** `in.ripngd` supports the following options:

- q Do not supply routing information.
- s Force `in.ripngd` to supply routing information whether it is acting as an internetwork router or not.
- p *n* Send and receive the routing packets from other routers using the UDP port number *n*.
- P Do not use poison reverse.
- t Print all packets sent or received to standard output. `in.ripngd` will not divorce itself from the controlling terminal. Accordingly, interrupts from the keyboard will kill the process.
- v Print all changes made to the routing tables to standard output with a timestamp.

Any other argument supplied is interpreted as the name of the file in which the actions of `in.ripngd`, as specified by this option or by `-t`, should be logged versus being sent to standard output.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWroute

**SEE ALSO** `in.routed(1M)`, `ioctl(2)`, `attributes(5)`, `udp(7P)`

Malkin, G., Minnear, R., *RFC 2080, RIPng for IPv6*, January 1997.

**NOTES** The kernel's routing tables may not correspond to those of `in.ripngd` for short periods of time while processes that utilize existing routes exit; the only remedy for this is to place the routing process in the kernel.

`in.ripngd` currently does not support all of the functionality of `in.routed(1M)`. Future releases may support more if appropriate.

`in.ripngd` initially obtains a routing table by examining the interfaces configured on a machine. It then sends a request on all directly connected networks for more routing

in.ripngd(1M)

information. `in.ripngd` does not recognize or use any routing information already established on the machine prior to startup. With the exception of interface changes, `in.ripngd` does not see any routing table changes that have been done by other programs on the machine, for example, routes added, deleted or flushed by way of the `route(1M)` command. Therefore, these types of changes should not be done while `in.ripngd` is running. Rather, shut down `in.ripngd`, make the changes required, and then restart `in.ripngd`.

## in.rlogind(1M)

<b>NAME</b>	in.rlogind, rlogind – remote login server												
<b>SYNOPSIS</b>	<code>/usr/sbin/in.rlogind</code>												
<b>DESCRIPTION</b>	<p><code>in.rlogind</code> is the server for the <code>rlogin(1)</code> program. The server provides a remote login facility with authentication based on privileged port numbers.</p> <p><code>in.rlogind</code> is invoked by <code>inetd(1M)</code> when a remote login connection is established, and executes the following protocol:</p> <ul style="list-style-type: none"><li>■ The server checks the client's source port. If the port is not in the range 512-1023, the server aborts the connection.</li><li>■ The server checks the client's source address. If an entry for the client exists in both <code>/etc/hosts</code> and <code>/etc/hosts.equiv</code>, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in <code>/etc/hosts</code>, the user is prompted for a password, regardless of whether or not an entry for the client is present in <code>/etc/hosts.equiv</code>. See <code>hosts(4)</code> and <code>hosts.equiv(4)</code>.</li></ul> <p>Once the source port and address have been checked, <code>in.rlogind</code> allocates a pseudo-terminal and manipulates file descriptors so that the slave half of the pseudo-terminal becomes the <code>stdin</code>, <code>stdout</code>, and <code>stderr</code> for a login process. The login process is an instance of the <code>login(1)</code> program, invoked with the <code>-r</code>.</p> <p>The login process then proceeds with the <code>pam(3PAM)</code> authentication process. See <code>SECURITY</code> below. If automatic authentication fails, it re-prompts the user to login.</p> <p>The parent of the login process manipulates the master side of the pseudo-terminal, operating as an intermediary between the login process and the client instance of the <code>rlogin</code> program. In normal operation, a packet protocol is invoked to provide Ctrl-S and Ctrl-Q type facilities and propagate interrupt signals to the remote programs. The login process propagates the client terminal's baud rate and terminal type, as found in the environment variable, <code>TERM</code>; see <code>environ(4)</code>.</p>												
<b>USAGE</b>	<code>rlogind</code> and <code>in.rlogind</code> are IPv6-enabled. See <code>ip6(7P)</code> .												
<b>SECURITY</b>	<p><code>in.rlogind</code> uses <code>pam(3PAM)</code> for authentication, account management, and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for <code>in.rlogind</code>. Here is a partial <code>pam.conf</code> file with entries for the <code>rlogin</code> command using the "rhosts" and UNIX authentication modules, and the UNIX account, session management, and password management modules.</p> <table><tr><td><code>rlogin</code></td><td><code>auth</code></td><td><code>sufficient</code></td><td><code>/usr/lib/security/pam_rhosts_auth.so.1</code></td></tr><tr><td><code>rlogin</code></td><td><code>auth</code></td><td><code>required</code></td><td><code>/usr/lib/security/pam_unix.so.1</code></td></tr><tr><td><code>rlogin</code></td><td><code>account</code></td><td><code>required</code></td><td><code>/usr/lib/security/pam_unix.so.1</code></td></tr></table>	<code>rlogin</code>	<code>auth</code>	<code>sufficient</code>	<code>/usr/lib/security/pam_rhosts_auth.so.1</code>	<code>rlogin</code>	<code>auth</code>	<code>required</code>	<code>/usr/lib/security/pam_unix.so.1</code>	<code>rlogin</code>	<code>account</code>	<code>required</code>	<code>/usr/lib/security/pam_unix.so.1</code>
<code>rlogin</code>	<code>auth</code>	<code>sufficient</code>	<code>/usr/lib/security/pam_rhosts_auth.so.1</code>										
<code>rlogin</code>	<code>auth</code>	<code>required</code>	<code>/usr/lib/security/pam_unix.so.1</code>										
<code>rlogin</code>	<code>account</code>	<code>required</code>	<code>/usr/lib/security/pam_unix.so.1</code>										

```
rlogin session required /usr/lib/security/pam_unix.so.1
```

With this configuration, the server checks the client's source address. If an entry for the client exists in both `/etc/hosts` and `/etc/hosts.equiv`, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in `/etc/hosts`, the user is prompted for a password, regardless of whether or not an entry for the client is present in `/etc/hosts.equiv`. See `hosts(4)` and `hosts.equiv(4)`.

If there are no entries for the `rlogin` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords. Removing the "pam\_rhosts\_auth.so.1" entry will disable the `/etc/hosts.equiv` and `~/rhosts` authentication protocol and the user would always be forced to type the password. The *sufficient* flag indicates that authentication through the `pam_rhosts_auth.so.1` module is "sufficient" to authenticate the user. Only if this authentication fails is the next authentication module used.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

**SEE ALSO** `login(1)`, `rlogin(1)`, `in.rshd(1M)`, `inetd(1M)`, `pam(3PAM)`, `environ(4)`, `hosts(4)`, `hosts.equiv(4)`, `inetd.conf(4)`, `pam.conf(4)`, `attributes(5)`, `pam_rhosts_auth(5)`, `pam_unix(5)`, `ip6(7P)`

**DIAGNOSTICS** All diagnostic messages are returned on the connection associated with the `stderr`, after which any network connections are closed. An error is indicated by a leading byte with a value of 1.

Hostname for your address unknown.

No entry in the host name database existed for the client's machine.

Try again.

A *fork* by the server failed.

/usr/bin/sh: ...

The user's login shell could not be started.

**NOTES** The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

## in.routed(1M)

<b>NAME</b>	in.routed, routed – network routing daemon
<b>SYNOPSIS</b>	<code>/usr/sbin/in.routed [-s] [-q] [-t] [-g] [-S] [-v] [logfile]</code>
<b>DESCRIPTION</b>	<p><code>in.routed</code> is invoked at boot time to manage the network routing tables. The routing daemon uses a variant of the Xerox NS Routing Information Protocol in maintaining up-to-date kernel routing table entries.</p> <p>At boot time, <code>in.routed</code> is invoked with either the <code>-s</code> or <code>-q</code> option. Options are described below. The <code>-s</code> option is appropriate for a router. The <code>in.routed -s</code> command is invoked under the following conditions:</p> <ul style="list-style-type: none"><li>■ A machine has multiple interfaces</li><li>■ The interfaces are not configured by DHCP</li><li>■ The <code>defaultrouter(4)</code> and <code>/etc/notrouter</code> files are not present</li></ul> <p>Otherwise, the <code>in.routed -q</code> command is invoked.</p> <p>In normal operation, <code>in.routed</code> listens on <code>udp(7P)</code> socket 520 (decimal) for routing information packets. If the host is an internetwork router, it periodically supplies copies of its routing tables to any directly connected hosts and networks.</p> <p>When <code>in.routed</code> is started, it uses the <code>SIOCGIFCONF ioctl(2)</code> to find those directly connected interfaces configured into the system and marked “up” (the software loopback interface is ignored). If multiple interfaces are present, it is assumed the host will forward packets between networks. <code>in.routed</code> then transmits a <i>request</i> packet on each interface (using a broadcast packet if the interface supports it) and enters a loop, listening for <i>request</i> and <i>response</i> packets from other hosts.</p> <p>When a <i>request</i> packet is received, <code>in.routed</code> formulates a reply based on the information maintained in its internal tables. The <i>response</i> packet contains a list of known routes, each marked with a “hop count” metric (a count of 16, or greater, is considered “infinite”). The metric associated with each route returned, provides a metric relative to the sender.</p> <p><i>request</i> packets received by <code>in.routed</code> are used to update the routing tables if one of the following conditions is satisfied:</p> <ul style="list-style-type: none"><li>■ No routing table entry exists for the destination network or host, and the metric indicates the destination is “reachable” (that is, the hop count is not infinite).</li><li>■ The source host of the packet is the same as the router in the existing routing table entry. That is, updated information is being received from the very internetwork router through which packets for the destination are being routed.</li><li>■ The existing entry in the routing table has not been updated for some time (defined to be 90 seconds) and the route is at least as cost effective as the current route.</li><li>■ The new route describes a shorter route to the destination than the one currently stored in the routing tables; the metric of the new route is compared against the one stored in the table to decide this.</li></ul>

in.routed(1M)

When an update is applied, `in.routed` records the change in its internal tables and generates a *response* packet to all directly connected hosts and networks. `in.routed` waits a short period of time (no more than 30 seconds) before modifying the kernel's routing tables to allow possible unstable situations to settle.

In addition to processing incoming packets, `in.routed` also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed an additional 60 seconds to insure the invalidation is propagated throughout the internet.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks.

In addition to the facilities described above, `in.routed` supports the notion of "distant" passive and active gateways. When `in.routed` is started up, it reads the file `gateways` to find gateways which may not be identified using the `STOCGIFCONF` ioctl. Gateways specified in this manner should be marked *passive* if they are not expected to exchange routing information, while gateways marked *active* should be willing to exchange routing information (that is, they should have a `in.routed` process running on the machine). Routes through passive gateways are installed in the kernel's routing tables once upon startup. They may change, depending upon routing information they receive from other gateways. Information regarding their existence is not included in any routing information transmitted. Active gateways are treated equally to network interfaces. Routing information is distributed to the gateway, and if no routing information is received for a period of time, the associated route is deleted.

The `gateways` file is comprised of a series of lines, each in the following format:

```
< net | host > filename1 gateway filename2 metric value < passive | active >
```

The `net` or `host` keyword indicates if the route is to a network or specific host.

*filename1* is the name of the destination network or host. This may be a symbolic name located in `networks` or `hosts`, or an Internet address specified in "dot" notation; see `inet(3SOCKET)`.

*filename2* is the name or address of the gateway to which messages should be forwarded.

*value* is a metric indicating the hop count to the destination host or network.

The keyword *passive* or *active* indicates if the gateway should be treated as passive or active (as described above).

## OPTIONS

`-g` Is used on internetwork routers to offer a route to the "default" destination. This is typically used on a gateway to the Internet, or on a gateway that uses another routing protocol whose routes are not reported to other local routers.

## in.routed(1M)

- q Is the opposite of the `-s` option.
- s Forces `in.routed` to supply routing information whether it is acting as an internetwork router or not.
- S If `in.routed` is not acting as an internetwork router it will, instead of entering the whole routing table in the kernel, only enter a default route for each internetwork router. This reduces the the memory requirements without losing any routing reliability.
- t All packets sent or received are printed on standard output. In addition, `in.routed` will not divorce itself from the controlling terminal so that interrupts from the keyboard will kill the process. Any other argument supplied is interpreted as the name of the file in which `in.routed`'s actions should be logged. This log contains information about any changes to the routing tables and a history of recent messages sent and received which are related to the changed route.
- v Allows a logfile (whose name must be supplied) to be created showing the changes made to the routing tables with a timestamp.

<b>FILES</b>	<code>/etc/defaultrouter</code>	list of defaultrouters
	<code>/etc/gateways</code>	list of distant gateways
	<code>/etc/hosts</code>	Internet host table
	<code>/etc/networks</code>	associations of Internet Protocol network numbers with network names
	<code>/etc/notrouter</code>	A file that acts as a flag for a boot-time script that determines whether a machine will act as a router or a host. The presence of the <code>notrouter</code> file prevents a machine that does not have a default route from acting as an IPv4 router, even if that machine has multiple interfaces.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWroute

**SEE ALSO** `route(1M)`, `ioctl(2)`, `inet(3SOCKET)`, `defaultrouter(4)`, `attributes(5)`, `inet(7P)`, `udp(7P)`

**NOTES** The kernel's routing tables may not correspond to those of `in.routed` for short periods of time while processes that utilize existing routes exit; the only remedy for this is to place the routing process in the kernel.

## in.routed(1M)

`in.routed` should listen to intelligent interfaces, such as an IMP, and to error protocols, such as ICMP, to gather more information.

`in.routed` initially obtains a routing table by examining the interfaces configured on a machine and the `gateways` file. It then sends a request on all directly connected networks for more routing information. `in.routed` does not recognize or use any routing information already established on the machine prior to startup. With the exception of interface changes, `in.routed` does not see any routing table changes that have been done by other programs on the machine, for example, routes added, deleted or flushed by way of the `route(1M)` command. Therefore, these types of changes should not be done while `in.routed` is running. Rather, shut down `in.routed`, make the changes required, and then restart `in.routed`.

## in.rshd(1M)

<b>NAME</b>	in.rshd, rshd – remote shell server
<b>SYNOPSIS</b>	<b>in.rshd</b> <i>host.port</i>
<b>DESCRIPTION</b>	<p><i>in.rshd</i> is the server for the <i>rsh(1)</i> program. The server provides remote execution facilities with authentication based on privileged port numbers.</p> <p><i>in.rshd</i> is invoked by <i>inetd(1M)</i> each time a shell service is requested, and executes the following protocol:</p> <ol style="list-style-type: none"><li>1. The server checks the client's source port. If the port is not in the range 512-1023, the server aborts the connection. The client's host address (in hex) and port number (in decimal) are the arguments passed to <i>in.rshd</i>.</li><li>2. The server reads characters from the socket up to a null ( \0 ) byte. The resultant string is interpreted as an ASCII number, base 10.</li><li>3. If the number received in step 2 is non-zero, it is interpreted as the port number of a secondary stream to be used for the <i>stderr</i>. A second connection is then created to the specified port on the client's machine. The source port of this second connection is also in the range 512-1023.</li><li>4. A null-terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as the user identity on the <i>client's</i> machine.</li><li>5. A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as a user identity to use on the <i>server's</i> machine.</li><li>6. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.</li><li>7. <i>in.rshd</i> then validates the user according to the following steps. The remote user name is looked up in the password file and a <i>chdir</i> is performed to the user's home directory. If the lookup fails, the connection is terminated. If the <i>chdir</i> fails, it does a <i>chdir</i> to / (root). If the user is not the superuser, (user ID 0), and if the <i>pam_rhosts_auth</i> PAM module is configured for authentication, the file <i>/etc/hosts.equiv</i> is consulted for a list of hosts considered "equivalent". If the client's host name is present in this file, the authentication is considered successful. See the SECURITY section below for a discussion of PAM authentication.  If the lookup fails, or the user is the superuser, then the file <i>.rhosts</i> in the home directory of the remote user is checked for the machine name and identity of the user on the client's machine. If this lookup fails, the connection is terminated</li><li>8. A null byte is returned on the connection associated with the <i>stderr</i> and the command line is passed to the normal login shell of the user. (The <i>PATH</i> variable is set to <i>/usr/bin</i>.) The shell inherits the network connections established by <i>in.rshd</i>.</li></ol>
<b>USAGE</b>	<i>rshd</i> and <i>in.rshd</i> are IPv6-enabled. See <i>ip6(7P)</i> .

**SECURITY** | in.rshd uses pam(3PAM) for authentication, account management, and session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in.rshd. Here is a partial pam.conf file with entries for the rsh command using rhosts authentication, UNIX account management, and session management module.

rsh	auth	required	/usr/lib/security/pam_rhosts_auth.so.1
rsh	account	required	/usr/lib/security/pam_unix.so.1
rsh	session	required	/usr/lib/security/pam_unix.so.1

If there are no entries for the rsh service, then the entries for the "other" service will be used. To maintain the authentication requirement for in.rshd, the rsh entry must always be configured with the pam\_rhosts\_auth.so.1 module.

**FILES** | /etc/hosts.equiv

**ATTRIBUTES** | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

**SEE ALSO** | rsh(1), inetd(1M), pam(3PAM), hosts(4), inetd.conf(4), pam.conf(4), attributes(5), pam\_rhosts\_auth(5), pam\_unix(5), ip6(7P)

**DIAGNOSTICS** | The following diagnostic messages are returned on the connection associated with stderr, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 in step 8 above (0 is returned above upon successful completion of all the steps prior to the command execution).

locuser too long

The name of the user on the client's machine is longer than 16 characters.

remuser too long

The name of the user on the remote machine is longer than 16 characters.

command too long

The command line passed exceeds the size of the argument list (as configured into the system).

Hostname for your address unknown.

No entry in the host name database existed for the client's machine.

Login incorrect.

No password file entry for the user name existed.

in.rshd(1M)

Permission denied.

The authentication procedure described above failed.

Can't make pipe.

The pipe needed for the `stderr` was not created.

Try again.

A *fork* by the server failed.

**NOTES** The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

<b>NAME</b>	in.rwhod, rwhod – system status server
<b>SYNOPSIS</b>	<code>/usr/sbin/in.rwhod [-m [ttl]]</code>
<b>DESCRIPTION</b>	<p><code>in.rwhod</code> is the server which maintains the database used by the <code>rwho(1)</code> and <code>rptime(1)</code> programs. Its operation is predicated on the ability to broadcast or multicast messages on a network.</p> <p><code>in.rwhod</code> operates as both a producer and consumer of status information. As a producer of information it periodically queries the state of the system and constructs status messages which are broadcast or multicast on a network. As a consumer of information, it listens for other <code>in.rwhod</code> servers' status messages, validating them, then recording them in a collection of files located in the directory <code>/var/spool/rwho</code>.</p> <p>The <code>rwho</code> server transmits and receives messages at the port indicated in the <code>rwho</code> service specification, see <code>services(4)</code>. The messages sent and received are defined in <code>/usr/include/protocols/rwhod.h</code> and are of the form:</p> <pre> struct outmp {     char    out_line[8];    /* tty name */     char    out_name[8];    /* user id */     long    out_time;      /* time on */ }; struct whod {     char    wd_vers;     char    wd_type;     char    wd_fill[2];     int     wd_sendtime;     int     wd_recvtime;     char    wd_hostname[32];     int     wd_loadav[3];     int     wd_boottime;     struct  whoent {         struct outmp we_utmp;         int     we_idle;     } wd_we[1024 / sizeof (struct whoent)]; }; </pre> <p>All fields are converted to network byte order prior to transmission. The load averages are as calculated by the <code>w(1)</code> program, and represent load averages over the 5, 10, and 15 minute intervals prior to a server's transmission. The host name included is that returned by the <code>uname(2)</code> system call. The array at the end of the message contains information about the users who are logged in to the sending machine. This information includes the contents of the <code>utmpx(4)</code> entry for each non-idle terminal line and a value indicating the time since a character was last received on the terminal line.</p> <p>Messages received by the <code>rwho</code> server are discarded unless they originated at a <code>rwho</code> server's port. In addition, if the host's name, as specified in the message, contains any unprintable ASCII characters, the message is discarded. Valid messages received by</p>

## in.rwhod(1M)

`in.rwhod` are placed in files named `whod.hostname` in the directory `/var/spool/rwho`. These files contain only the most recent message, in the format described above.

Status messages are generated approximately once every 3 minutes.

**OPTIONS** `-m [ ttl ]` Use the `rwho` IP multicast address (224.0.1.3) when transmitting. Receive announcements both on this multicast address and on the IP broadcast address. If `ttl` is not specified `in.rwhod` will multicast on all interfaces but with the IP TimeToLive set to 1 (that is, packets will not be forwarded by multicast routers.) If `ttl` is specified `in.rwhod` will only transmit packets on one interface and setting the IP TimeToLive to the specified `ttl`.

**FILES** `/var/spool/rwho/whod.*` information about other machines

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

**SEE ALSO** `ruptime(1)`, `rwho(1)`, `w(1)`, `uname(2)`, `services(4)`, `utmpx(4)`, `attributes(5)`

**WARNINGS** This service can cause network performance problems when used by several hosts on the network. It is not run at most sites by default. If used, include the `-m` multicast option.

**NOTES** This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

`in.rwhod` should relay status information between networks. People often interpret the server dying as a machine going down.

<b>NAME</b>	install – install commands
<b>SYNOPSIS</b>	<pre> /usr/sbin/install -c <i>dira</i> [-m <i>mode</i>] [-u <i>user</i>] [-g <i>group</i>] [-o] [-s] <i>file</i> /usr/sbin/install -f <i>dirb</i> [-m <i>mode</i>] [-u <i>user</i>] [-g <i>group</i>] [-o] [-s] <i>file</i> /usr/sbin/install -n <i>dirc</i> [-m <i>mode</i>] [-u <i>user</i>] [-g <i>group</i>] [-o] [-s] <i>file</i> /usr/sbin/install -d   -i [-m <i>mode</i>] [-u <i>user</i>] [-g <i>group</i>] [-o] [-s]     <i>dirx...</i> /usr/sbin/install [-m <i>mode</i>] [-u <i>user</i>] [-g <i>group</i>] [-o] [-s] <i>file</i> [<i>dirx...</i>] </pre>
<b>DESCRIPTION</b>	<p>install is most commonly used in “makefiles” (see make(1S)) to install a file in specific locations, or to create directories within a file system. Each file is installed by copying it into the appropriate directory.</p> <p>install uses no special privileges to copy files from one place to another. The implications of this are:</p> <ul style="list-style-type: none"> <li>■ You must have permission to read the files to be installed.</li> <li>■ You must have permission to copy into the destination directory.</li> <li>■ You must have permission to change the modes on the final copy of the file if you want to use the -m option.</li> <li>■ You must be super-user if you want to specify the ownership of the installed file with the -u or -g options. If you are not the super-user, the installed file will be owned by you, regardless of who owns the original.</li> </ul> <p>install prints messages telling the user exactly what files it is replacing or creating and where they are going.</p> <p>If no options or directories (<i>dirx . . .</i>) are given, install searches a set of default directories ( /bin, /usr/bin, /etc, /lib, and /usr/lib, in that order) for a file with the same name as <i>file</i>. When the first occurrence is found, install issues a message saying that it is overwriting that file with <i>file</i>, and proceeds to do so. If the file is not found, the program states this and exits.</p> <p>If one or more directories (<i>dirx . . .</i>) are specified after <i>file</i>, those directories are searched before the default directories.</p>
<b>OPTIONS</b>	<p>-c <i>dira</i>            Install <i>file</i> in the directory specified by <i>dira</i>, if <i>file</i> does not yet exist. If it is found, install issues a message saying that the file already exists, and exits without overwriting it.</p> <p>-f <i>dirb</i>            Force <i>file</i> to be installed in given directory, even if the file already exists. If the file being installed does not already exist, the mode and owner of the new file will be set to 755 and bin , respectively. If the file already exists, the mode and owner will be that of the already existing file.</p>

## install(1M)

- n *dir* If *file* is not found in any of the searched directories, it is put in the directory specified in *dir*. The mode and owner of the new file will be set to 755 and *bin*, respectively.
- d Create a directory. Missing parent directories are created as required as in `mkdir -p`. If the directory already exists, the owner, group and mode will be set to the values given on the command line.
- i Ignore default directory list, searching only through the given directories (*dirx . . .*).
- m *mode* The mode of the new file is set to *mode*. Set to 0755 by default.
- u *user* The owner of the new file is set to *user*. Only available to the super-user. Set to *bin* by default.
- g *group* The group id of the new file is set to *group*. Only available to the super-user. Set to *bin* by default.
- o If *file* is found, save the "found" file by copying it to *OLDfile* in the directory in which it was found. This option is useful when installing a frequently used file such as `/bin/sh` or `/lib/saf/ttymon`, where the existing file cannot be removed.
- s Suppress printing of messages other than error messages.

**USAGE** See `largefile(5)` for the description of the behavior of `install` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `chgrp(1)`, `chmod(1)`, `chown(1)`, `cp(1)`, `make(1S)`, `mkdir(1)`, `chown(1M)`, `attributes(5)`, `largefile(5)`

<b>NAME</b>	installboot – install bootblocks in a disk partition				
<b>SPARC</b>	<b>installboot</b> <i>bootblk raw-disk-device</i>				
<b>IA</b>	<b>installboot</b> <i>pboot bootblk raw-disk-device</i>				
<b>DESCRIPTION</b>	<p>The boot(1M) program, <i>ufsboot</i>, is loaded from disk by the bootblock program which resides in the boot area of a disk partition.</p> <p>The <i>ufs</i> boot objects are platform-dependent, and reside in the <code>/usr/platform/<i>platform-name</i>/lib/fs/ufs</code> directory. The platform name can be found using the <code>-i</code> option of <code>uname(1)</code>.</p>				
<b>OPERANDS</b>	<p><i>bootblk</i>            The name of the bootblock code.</p> <p><i>raw-disk-device</i>    The name of the disk device onto which the bootblock code is to be installed; it must be a character device which is readable and writable. Naming conventions for a SCSI or IPI drive are <code>c?t?d?s?</code> and <code>c?d?s?</code> for an IDE drive.</p> <p><i>pboot</i>              The name of the partition boot file.</p>				
<b>SPARC</b>	<p>To install a <i>ufs</i> bootblock on slice 0 of target 0 on controller 1 of the platform where the command is being run, use:</p> <pre>example# installboot /usr/platform/'uname -i'/lib/fs/ufs/bootblk \ /dev/rdisk/c1t0d0s0</pre>				
<b>IA</b>	<p>To use <code>installboot</code> to install the <i>ufs</i> bootblock and partition boot program on a disk in an IA machine, you must specify slice 2 and that slice must be the entire disk. For example, to install the UFS bootblock on target 0, controller 1 of the platform where the command is being run, use:</p> <pre>example# installboot /usr/platform/'uname -i'/lib/fs/ufs/pboot \ /usr/platform/'uname -i '/lib/fs/ufs/bootblk /dev/rdisk/c1t0d0s2</pre>				
<b>FILES</b>	<p><code>/usr/platform/<i>platform-name</i>/lib/fs/ufs</code> directory where <i>ufs</i> boot objects reside.</p> <p><code>/platform/<i>platform-name</i>/ufsboot</code> second level program to boot from a disk or CD</p>				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

installboot(1M)

*Solaris 9 Installation Guide*

**SPARC** monitor(1M)

**IA** fdisk(1M), fmthard(1M)

**WARNINGS** The `installboot` utility fails if the `bootblk`, `pboot` or `openfirmware` files do not exist or if the raw disk device is not a character device.

<b>NAME</b>	installer – Solaris Web Start installer utility
<b>SYNOPSIS</b>	<b>installer</b> [-locales <i>list</i> ] [-nodisplay] [-debug]
<b>DESCRIPTION</b>	<p>The <b>installer</b> utility invokes a Web Start install wizard sequence which will lead the user through a sequence of installation panels. This installer utility is found on many CDs that are shipped with Solaris and it will be found among the top level files of these CDs.</p> <p>When the installer is on a CD being accessed from a desktop file manager, the installer can be double clicked to start the installation sequence. If the user is not currently the system's root user, the root user password will be requested.</p> <p>The installer utility can also be run from other UNIX scripts. Usually, a script is used in conjunction with the utility's <b>-nodisplay</b> option.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><b>-locales <i>list</i></b>      Selects product translations for install, corresponding to the specified list of locales if the specified locale translations are present on the installation media. Locales are supplied in a comma-separated list following the <b>-locales</b> option. An example <i>list</i> would appear as follows:</p> <p style="padding-left: 40px;"><b>installer -locales fr,de,it</b> This would install products with translations for the French, German, and Italian locales.</p> <p><b>-nodisplay</b>      Runs the install without a graphic user interface. Use the default product install unless it was modified by the <b>-locales</b> options.</p> <p><b>-debug</b>      Outputs extra information about what the install is doing. Mainly for install diagnostic purposes.</p>
<b>FILES</b>	<b>/var/sadm/install/logs</b> location of installation log files

## installf(1M)

<b>NAME</b>	installf – add a file to the software installation database										
<b>SYNOPSIS</b>	<b>installf</b> [-c <i>class</i> ] [ [-M] -R <i>root_path</i> ] [-V <i>fs_file</i> ] <i>pkginst pathname</i> [ <i>ftype</i> [ <i>major minor</i> ] [ <i>mode owner group</i> ]]  <b>installf</b> [-c <i>class</i> ] [ [-M] -R <i>root_path</i> ] [-V <i>fs_file</i> ] <i>pkginst</i>  <b>installf</b> -f [-c <i>class</i> ] [ [-M] -R <i>root_path</i> ] [-V <i>fs_file</i> ] <i>pkginst</i>										
<b>DESCRIPTION</b>	<p>installf informs the system that a pathname not listed in the pkgmap(4) file is being created or modified. It should be invoked before any file modifications have occurred.</p> <p>When the second synopsis is used, the pathname descriptions will be read from standard input. These descriptions are the same as would be given in the first synopsis but the information is given in the form of a list. The descriptions should be in the form:</p> <pre><i>pathname</i> [<i>ftype</i> [ <i>major minor</i> ] [ <i>mode owner group</i> ] ]</pre> <p>After all files have been appropriately created and/or modified, installf should be invoked with the -f synopsis to indicate that installation is final. Links will be created at this time and, if attribute information for a pathname was not specified during the original invocation of installf, or was not already stored on the system, the current attribute values for the pathname will be stored. Otherwise, installf verifies that attribute values match those given on the command line, making corrections as necessary. In all cases, the current content information is calculated and stored appropriately.</p>										
<b>OPTIONS</b>	<table><tr><td>-c <i>class</i></td><td>Class to which installed objects should be associated. Default class is none.</td></tr><tr><td>-f</td><td>Indicates that installation is complete. This option is used with the final invocation of installf (for all files of a given class).</td></tr><tr><td>-M</td><td>Instruct installf not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.</td></tr><tr><td>-R <i>root_path</i></td><td>Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i>).</td></tr><tr><td>-V <i>fs_file</i></td><td>Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.</td></tr></table>	-c <i>class</i>	Class to which installed objects should be associated. Default class is none.	-f	Indicates that installation is complete. This option is used with the final invocation of installf (for all files of a given class).	-M	Instruct installf not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.	-R <i>root_path</i>	Define the full path name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> . The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i> ).	-V <i>fs_file</i>	Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.
-c <i>class</i>	Class to which installed objects should be associated. Default class is none.										
-f	Indicates that installation is complete. This option is used with the final invocation of installf (for all files of a given class).										
-M	Instruct installf not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.										
-R <i>root_path</i>	Define the full path name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> . The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i> ).										
-V <i>fs_file</i>	Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.										

<b>OPERANDS</b>	<i>pkginst</i>	Name of package instance with which the pathname should be associated.
	<i>pathname</i>	Pathname that is being created or modified.
	<i>ftype</i>	A one-character field that indicates the file type. Possible file types include: <ul style="list-style-type: none"> <li>b        block special device</li> <li>c        character special device</li> <li>d        directory</li> <li>e        a file to be edited upon installation or removal</li> <li>f        a standard executable or data file</li> <li>l        linked file</li> <li>p        named pipe</li> <li>s        symbolic link</li> <li>v        volatile file (one whose contents are expected to change)</li> <li>x        an exclusive directory</li> </ul>
	<i>major</i>	The major device number. The field is only specified for block or character special devices.
	<i>minor</i>	The minor device number. The field is only specified for block or character special devices.
	<i>mode</i>	The octal mode of the file (for example, 0664). A question mark (?) indicates that the mode will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.
	<i>owner</i>	The owner of the file (for example, <code>bin</code> or <code>root</code> ). The field is limited to 14 characters in length. A question mark (?) indicates that the owner will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.
	<i>group</i>	The group to which the file belongs (for example, <code>bin</code> or <code>sys</code> ). The field is limited to 14 characters in length. A question mark (?) indicates that the group will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.

## installf(1M)

### EXAMPLES

**EXAMPLE 1** The use of `installf`.

The following example shows the use of `installf`, invoked from an optional pre-install or post-install script:

```
#create /dev/xt directory
#(needs to be done before drvininstall)
installf $PKGINST /dev/xt d 755 root sys ||
 exit 2
majno='/usr/sbin/drvininstall -m /etc/master.d/xt
 -d $BASEDIR/data/xt.o -v 1.0' ||
 exit 2
i=00
while [$i -lt $limit]
do
 for j in 0 1 2 3 4 5 6 7
 do
 echo /dev/xtij c $majno `expr $i ? 8 + $j`
 644 root sys |
 echo /dev/xtij=/dev/xt/ij
 done
 i=`expr $i + 1`
 [$i -le 9] && i="0$i" #add leading zero
done | installf $PKGINST - || exit 2
finalized installation, create links
installf -f $PKGINST || exit 2
```

### EXIT STATUS

0 Successful operation.  
>0 An error occurred.

*Application Packaging Developer's Guide*

### NOTES

When `ftype` is specified, all applicable fields, as shown below, must be defined:

<i>ftype</i>	Required Fields
p, x, d, f, v, or e	mode owner group
c or b	major minor mode owner group

The `installf` command will create directories, named pipes and special devices on the original invocation. Links are created when `installf` is invoked with the `-f` option to indicate installation is complete.

Links should be specified as `path1=path2`. `path1` indicates the destination and `path2` indicates the source file.

Files installed with `installf` will be placed in the class `none`, unless a class is defined with the command. Subsequently, they will be removed when the associated package is deleted. If this file should not be deleted at the same time as the package, be certain to assign it to a class which is ignored at removal time. If special action is required for the file before removal, a class must be defined with the command and an appropriate class action script delivered with the package.

When classes are used, `installf` must be used in one of the following forms:

```
installf -c class1 . . .
installf -f -c class1 . . .
installf -c class2 . . .
installf -f -c class2 . . .
```

## install\_scripts(1M)

<b>NAME</b>	install_scripts, add_install_client, add_to_install_server, modify_install_server, rm_install_client, setup_install_server, check – scripts used to install the Solaris software
<b>SYNOPSIS</b>	<pre>cdrom-mnt-pt/Solaris_XX/Tools/add_install_client [-i IP_address] [-e Ethernet_address] [-s server_name : path] [-c server_name : path] [-n [server ] : name_service [( netmask)] [-p server_name : path] [-f boot_file_name] host_name platform_group  cdrom-mnt-pt/Solaris_XX/Tools/add_install_client -d [-s server_name:path] [-c server_name:path] [-p server_name:path] [-t install_boot_image_path] [-f boot_file_name] platform_name platform_group  cdrom-mnt-pt/Solaris_XX/Tools/add_install_client -d [-s server_name:path] [-c server_name:path] [-p server_name:path] [-t install_boot_image_path] [-f boot_file_name] -e Ethernet_address platform_group  cdrom-mnt-pt/Solaris_XX/Tools/add_to_install_server [-s] [-p product_image_path] install_server_path  cdrom-mnt-pt/Solaris_XX/Tools/jumpstart_sample/check [-p install_dir_path] [-r rulesfile]  cdrom-mnt-pt/modify_install_server [-p] install_dir_path installer_miniroot_path  cdrom-mnt-pt/Solaris_XX/Tools/rm_install_client host_name  cdrom-mnt-pt/Solaris_XX/Tools/setup_install_server [-b] [-t install_boot_image_path] install_dir_path</pre>
<b>DESCRIPTION</b>	<p>These commands are located on slice 0 of the Solaris Software and Solaris Installer CDs. If the Solaris CD has been copied to a local disk, <code>cdrom_mnt_pt</code> is the path to the copied Solaris CD. They can be used for a variety of installation tasks.</p> <p>The <code>XX</code> in <code>Solaris_XX</code> is the version number of the Solaris release being used.</p> <p>There are three versions of the <code>add_install_client</code> command. See <b>SYNOPSIS</b>.</p> <p>Use the following version of the <code>add_install_client</code> command to add clients for network installation (these commands update the <code>bootparams(4)</code> file). The <code>add_install_client</code> command must be run from the install server's Solaris installation image (a mounted Solaris CD or a Solaris CD copied to disk) or the boot server's boot directory (if a boot server is required). The Solaris installation image or the boot directory must be the same Solaris release that you want installed on the client.</p> <pre>cdrom-mnt-pt/Solaris_XX/Tools/add_install_client [-i IP_address] [-e Ethernet_address] [-s server_name : path] [-c server_name : path] [-n [server ] : name_service [( netmask)] [-p server_name : path] host_name platform_group</pre>

Use the following version of the `add_install_client` command to add support for instances of a platform within a platform group to the install server. This group will be booted and configured using DHCP. The script will perform the necessary configuration steps on the server, and prints the data that the user needs to add to the DHCP server for the group.

```
cdrom-mnt-pt/Solaris_XX/Tools/add_install_client -d [-s server:path]
[-c server:path] [-p server:path] [-t install boot image path] [-f boot file
name] platform_name platform_group
```

Use the following version of the `add_install_client` command to add a single client to the install server. This client will be booted and configured using DHCP. The script will perform the necessary configuration steps on the server, and will print the data that the user needs to add to the DHCP server for the client. The `-f` flag used above needs to be added to the existing usage as well. `-f` allows the user to specify a boot file name to be used for a given client.

```
cdrom-mnt-pt/Solaris_XX/Tools/add_install_client -d [-s
server_name:path] [-c server_name:path] [-p server_name:path] [-t
install_boot_image_path] [-f boot_file_name] -e Ethernet_address platform_group
```

**Note** – Always use the `-d` option when registering Intel Architecture (IA) Pre-boot eXecution Environment (PXE) clients. These clients use DHCP for their configuration.

Use `add_to_install_server` to merge other Solaris CDs with an existing image on a Net Install Server. Each CD that can be merged (currently OS CD 2, and the Language CD) has its own `add_to_install_server` script. Do not use `add_to_install_server` scripts with CDs other than the ones with which they were delivered.

Use `check` to validate the rules in a `rules` file (this is only necessary if a custom JumpStart installation is being set up).

Use `modify_install_server` to replace an existing net install server's miniroot with a Solaris Installation CD's miniroot. This will change the net install server's install time user interface over to the Solaris Installation CD's Web Start user interface.

An existing install image (created using `setup_install_server`) must exist prior to using the `modify_install_server` command.

Use `rm_install_client` to remove clients for network installation (these commands update the `bootparams(4)` file).

Use `setup_install_server` to copy the Solaris CD to a disk (to set up an install server) or to copy just the boot software of the Solaris CD to a disk (to set up a boot server). An install server is required to install clients over the network. A boot server is also required for network installations if the install server and clients to be installed are on different subnets (the boot server must be located on the client's subnet).

**OPTIONS** The `add_install_client` supports the following options:

## install\_scripts(1M)

- c *server\_name* : *path*  
This option is required only to specify a JumpStart directory for a custom JumpStart installation. *server\_name* is the host name of the server with a JumpStart directory. *path* is the absolute path to the JumpStart directory.
  - d  
Specify as a DHCP client.
  - e *Ethernet\_address*  
Specify the Ethernet address of the system to be installed.
  - f  
Specify the *boot\_file\_name* of the client to be installed.
  - i *IP\_address*  
Specify the IP address of the client to be installed.
  - n [*server*]: *name\_service*[(*netmask*)]  
This option specifies which name service should be used during system configuration. This sets the ns keyword in the bootparams(4) file.  
*name\_service*  
Valid entries are nis, nisplus, and none.  
*netmask*  
A series of four numbers separated by periods, specifying which portion of an IP address is the network part, and which is the host part.  
*server*  
The name of the server or IP address of the specified name service. If the server specified is on a different subnet, then the *netmask* may be needed to enable the client to contact the server.
  - p *server\_name* : *path*  
This option is the location of the user-defined sysidcfg file for pre-configuring system or network information. *server\_name* is either a valid host name or IP address. *path* is the absolute path to the Jumpstart directory.
  - s *server\_name* : *path*  
This option is required only when using add\_install\_client from a boot server. Specify the name of the server and the absolute path of the Solaris installation image that will be used for this installation. *path* is either the path to a mounted Solaris CD or a path to a directory with a copy of the Solaris CD.
- The add\_to\_install\_server command supports the following options:
- p  
Specifies the location of the CD (containing the supplemental products) to be copied.
  - s  
Allows users to select from a list only the products needing installation.

The check command supports the following options:

**-p** *install\_dir\_path*

Validates the rules file by using the check script from a specified Solaris installation image, instead of the check script from the system you are using. *install\_dir\_path* is the path to a Solaris installation image on a local disk or a mounted Solaris CD.

Use this option to run the most recent version of check if your system is running a previous version of Solaris.

**-r** *rulesfile*

Specifies a rules file other than the one named *rules*. Using this option, the validity of a rule can be tested before integrating it into the rules file. *check* will report whether or not the rule is valid, but it will not create the *rules.ok* file necessary for a custom JumpStart installation.

The modify\_install\_server command supports the following options:

**-p**

This option preserves the existing images miniroot in *install\_dir\_path/Solaris\_XX/Tools/Boot.orig*.

The setup\_install\_server command supports the following options:

**-b**

This option sets up the server only as a boot server.

**-t**

This option allows an alternate miniroot to be specified.

## OPERANDS

The add\_install\_client command supports the following options:

*host\_name*

This is the name of the client to be installed.

*platform\_group*

Vendor-defined grouping of hardware platforms for the purpose of distributing specific software. Examples of valid platform groups are:

System	Platform Group
IA	i86pc
SPARCstation 1+	sun4c
SPARCstation 5	sun4m

Use the *uname(1)* command (with the *-m* option) to determine a system's platform group.

## install\_scripts(1M)

### *platform\_name*

Use the `uname(1)` command (with the `-i` option) to determine a system's platform name.

The following example shows the use of the `uname` command to determine the system platform name for an Ultra 1:

```
uname -i
```

The system responds with:

```
SUNW,Ultra-1
```

Therefore, the system's platform name is `SUNW,Ultra1`.

The following command calls `add_install_client` for Ultra 1s:

```
add_install_client -d SUNW,Ultra-1 sun4u
```

For IA32 platforms, the platform name is always `SUNW.i86pc`.

The following command calls `add_install_client` for IA32 platforms:

```
add_install_client -d SUNW.i86pc i86pc
```

The `rm_install_client` command supports the following operands:

### *host\_name*

This is the name of the client to be removed.

The `setup_install_server` command supports the following options:

### *install\_dir\_path*

The absolute path of the directory in which the Solaris software is to be copied. The directory must be empty.

## EXAMPLES

### EXAMPLE 1 Using `add_install_client`

The following `add_install_client` commands add clients for network installation from a mounted Solaris CD on an install server on Solaris 8:

```
example# cd /cdrom/cdrom0/s0/Solaris_8/Tools
example# ./add_install_client system_1 sun4c
example# ./add_install_client system_2 sun4m
```

### EXAMPLE 2 Using `add_install_client`

The following `add_install_client` commands add clients for network installation from a mounted Solaris CD on an install server. The `-c` option specifies a server and path to a JumpStart directory that has a rules file and a profile file for performing a custom JumpStart installation. Also, the Solaris CD has been copied to the `/export/install` directory on Solaris 8:

```
example# cd /export/install/Solaris_8/Tools
example# ./add_install_client -c install_server:/jumpstart system_1 i86pc
example# ./add_install_client -c install_server:/jumpstart system_2 i86pc
```

**EXAMPLE 2** Using `add_install_client` (Continued)

**EXAMPLE 3** Using `add_install_client`

The following `add_install_client` command adds support for a specific sun4u platform machine (8:0:20:99:88:77) using the boot file: `sun4u.solaris8`.

```
example# add_install_client -d -f sun4u.solaris8 -e 8:0:20:99:88:77 sun4u
```

**EXAMPLE 4** Using `add_install_client`

The following `add_install_client` command adds IA clients that use the PXE standard for network booting:

```
example# add_install_client -d -s svrname:/mnt/export/root SUNW.i86pc i86p
```

**EXAMPLE 5** Using `add_to_install_server`

The following `add_to_install_server` command copies the packages in all the CD's products directories to an existing install server on Solaris 8:

```
example# cd /cdrom/cdrom0/s0
example# ./add_to_install_server /export/Solaris_8
```

**EXAMPLE 6** Using `check`

The following `check` command validates the syntax of the rules file used for a custom JumpStart installation:

```
example# cd jumpstart_dir_path
example# ./check -p /cdrom/cdrom0/s0
```

**EXAMPLE 7** Using `modify_install_server`

The following `modify_install_server` command moves the miniroot created using the above `setup_install_server` to `Boot.orig` and replaces it with the miniroot on the Solaris Installer CD.

```
example# cd /cdrom/cdrom0/s0
example# ./modify_install_server -p /export/install /cdrom/cdrom0/s1
```

**EXAMPLE 8** Using `modify_install_server`

The following `modify_install_server` command replaces the miniroot created using the above `setup_install_server` with the miniroot on the Solaris Installer CD.

```
example# cd /cdrom/cdrom0/s0
example# ./modify_install_server /export/install /cdrom/cdrom0/s1
```

## install\_scripts(1M)

**EXAMPLE 8** Using `modify_install_server` (Continued)

**EXAMPLE 9** Using `rm_install_client`

The following `rm_install_client` commands remove clients for network installation on Solaris 8:

```
example# cd /export/install/Solaris_8/Tools
example# ./rm_install_client holmes
example# ./rm_install_client watson
```

**EXAMPLE 10** Using `setup_install_server`

The following `setup_install_server` command copies the mounted Solaris CD to a directory named `/export/install` on the local disk on Solaris 8:

```
example# cd /cdrom/cdrom0/s0/Solaris_8/Tools
example# ./setup_install_server /export/install
```

**EXAMPLE 11** Using `setup_install_server`

The following `setup_install_server` command copies the boot software of a mounted Solaris CD to a directory named `/boot_dir` on a system that is going to be a boot server for a subnet on Solaris 8:

```
example# cd /cdrom/cdrom0/s0/Solaris_8/Tools
example# ./setup_install_server -b /boot_dir
```

**EXAMPLE 12** Using `setup_install_server`

By default, `setup_install_server` will look for an installation boot directory at the Solaris `../Tools/Boot` location of the mount Solaris distribution disc.

If an alternate boot directory is required, such as one saved on a > network boot server by way of an earlier `./setup_install_server -b /boot_dir` command, the `-t` option can be used.

```
example# cd /cdrom/cdrom0/s0/Solairs_9/Tools
example# ./setup_install_server -t /boot_dir /export/install
```

**EXIT STATUS** The following exit values are returned:

0	Successful completion.
1	An error has occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

*Solaris Installation Guide*

in.talkd(1M)

**NAME** in.talkd, talkd – server for talk program

**SYNOPSIS** **in.talkd**

**DESCRIPTION** talkd is a server used by the talk(1) program. It listens at the UDP port indicated in the “talk” service description; see services(4). The actual conversation takes place on a TCP connection that is established by negotiation between the two machines involved.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

**SEE ALSO** talk(1), inetd(1M), services(4), attributes(5)

**NOTES** The protocol is architecture dependent.

<b>NAME</b>	in.telnetd, telnetd – DARPA TELNET protocol server
<b>SYNOPSIS</b>	<code>/usr/sbin/in.telnetd</code>
<b>DESCRIPTION</b>	<p><code>in.telnetd</code> is a server that supports the DARPA standard TELNET virtual terminal protocol. <code>in.telnetd</code> is normally invoked in the internet server (see <code>inetd(1M)</code>), for requests to connect to the TELNET port as indicated by the <code>/etc/services</code> file (see <code>services(4)</code>).</p> <p><code>in.telnetd</code> operates by allocating a pseudo-terminal device for a client, then creating a login process which has the slave side of the pseudo-terminal as its standard input, output, and error. <code>in.telnetd</code> manipulates the master side of the pseudo-terminal, implementing the TELNET protocol and passing characters between the remote client and the login process.</p> <p>When a TELNET session starts up, <code>in.telnetd</code> sends TELNET options to the client side indicating a willingness to do <i>remote echo</i> of characters, and to <i>suppress go ahead</i>. The pseudo-terminal allocated to the client is configured to operate in “cooked” mode, and with XTABS, ICRNL and ONLCR enabled. See <code>termio(7I)</code>.</p> <p><code>in.telnetd</code> is willing to do: <i>echo</i>, <i>binary</i>, <i>suppress go ahead</i>, and <i>timing mark</i>.  <code>in.telnetd</code> is willing to have the remote client do: <i>binary</i>, <i>terminal type</i>, <i>terminal size</i>, <i>logout option</i>, and <i>suppress go ahead</i>.</p> <p><code>in.telnetd</code> also allows environment variables to be passed, provided that the client negotiates this during the initial option negotiation. The DISPLAY environment variable may be sent this way, either by the TELNET general environment passing methods, or by means of the XDISPLOC TELNET option. DISPLAY can be passed in the environment option during the same negotiation where XDISPLOC is used. Note that if you use both methods, use the same value for both. Otherwise, the results may be unpredictable.</p> <p>These options are specified in Internet standards RFC 1096, RFC 1408, RFC 1571, and RFC 1572.</p> <p>The banner printed by <code>in.telnetd</code> is configurable. The default is (more or less) equivalent to “<code>uname -sr</code>” and will be used if no banner is set in <code>/etc/default/telnetd</code>. To set the banner, add a line of the form</p> <pre>BANNER="...to /etc/default/telnetd. Nonempty banner strings are fed to shells for evaluation. The default banner may be obtained by BANNER="\\r\\n\\r\\n'uname -s' 'uname -r'\\r\\n\\x\\n"and no banner will be printed if /etc/default/telnetd contains BANNER=""</pre>
<b>USAGE</b>	<code>telnetd</code> and <code>in.telnetd</code> are IPv6-enabled. See <code>ip6(7P)</code> .

## in.telnetd(1M)

**SECURITY** | `in.telnetd` uses `pam(3PAM)` for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `in.telnetd`. Here is a partial `pam.conf` file with entries for the `telnet` command using the UNIX authentication, account management, session management, and password management modules.

telnet	auth	required	/usr/lib/security/pam_unix.so.1
telnet	account	required	/usr/lib/security/pam_unix.so.1
telnet	session	required	/usr/lib/security/pam_unix.so.1
telnet	password	required	/usr/lib/security/pam_unix.so.1

If there are no entries for the `telnet` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

**FILES** | `/etc/default/telnetd`

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtnetd

**SEE ALSO** | `telnet(1)`, `inetd(1M)`, `pam(3PAM)`, `inetd.conf(4)`, `pam.conf(4)`, `services(4)`, `attributes(5)`, `pam_unix(5)`, `ip6(7P)`, `termio(7I)`

Alexander, S., *TELNET Environment Option*, RFC 1572, Network Information Center, SRI International, Menlo Park, Calif., January 1994.

Borman, Dave, *TELNET Environment Option*, RFC 1408, Network Information Center, SRI International, Menlo Park, Calif., January 1993.

Borman, Dave, *TELNET Environment Option Interoperability Issues*, RFC 1571, Network Information Center, SRI International, Menlo Park, Calif., January 1994.

Crispin, Mark, *TELNET Logout Option*, RFC 727, Network Information Center, SRI International, Menlo Park, Calif., April 1977.

Marcy, G., *TELNET X Display Location Option*. RFC 1096, Network Information Center, SRI International, Menlo Park, Calif., March 1989.

Postel, Jon, and Joyce Reynolds, *TELNET Protocol Specification*, RFC 854, Network Information Center, SRI International, Menlo Park, Calif., May 1983.

in.telnetd(1M)

Waitzman, D., *TELNET Window Size Option*, RFC 1073, Network Information Center, SRI International, Menlo Park, Calif., October 1988.

**NOTES** Some TELNET commands are only partially implemented.

Binary mode has no common interpretation except between similar operating systems.

The terminal type name received from the remote client is converted to lower case.

The *packet* interface to the pseudo-terminal should be used for more intelligent flushing of input and output queues.

in.telnetd never sends TELNET *go ahead* commands.

## in.tftpd(1M)

<b>NAME</b>	in.tftpd, tftpd – Internet Trivial File Transfer Protocol server				
<b>SYNOPSIS</b>	<b>in.tftpd</b> [-s] [ <i>homedir</i> ]				
<b>DESCRIPTION</b>	<p>tftpd is a server that supports the Internet Trivial File Transfer Protocol (TFTP). This server is normally started by <code>inetd(1M)</code> and operates at the port indicated in the <code>tftp</code> Internet service description in the <code>/etc/inetd.conf</code> file. By default, the entry for <code>in.tftpd</code> in <code>etc/inetd.conf</code> is commented out. To make <code>in.tftpd</code> operational, the comment character(s) must be deleted from the file. See <code>inetd.conf(4)</code>.</p> <p>Before responding to a request, the server attempts to change its current directory to <i>homedir</i>; the default directory is <code>/tftpboot</code>.</p> <p>The use of <code>tftp</code> does not require an account or password on the remote system. Due to the lack of authentication information, <code>in.tftpd</code> will allow only publicly readable files to be accessed. Files may be written only if they already exist and are publicly writable. Note that this extends the concept of “public” to include all users on all hosts that can be reached through the network; this may not be appropriate on all systems, and its implications should be considered before enabling this service.</p> <p><code>in.tftpd</code> runs with the user ID and group ID set to <code>[GU] ID_NOBODY</code> under the assumption that no files exist with that owner or group. However, nothing checks this assumption or enforces this restriction.</p>				
<b>OPTIONS</b>	<code>-s</code> Secure. When specified, the directory change to <i>homedir</i> must succeed. The daemon also changes its root directory to <i>homedir</i> .				
<b>FILES</b>	<code>/etc/inetd.conf</code>				
<b>USAGE</b>	The <code>in.tftpd</code> server is IPv6-enabled. See <code>ip6(7P)</code> .				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWtftp</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWtftp
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWtftp				
<b>SEE ALSO</b>	<code>tftp(1)</code> , <code>inetd(1M)</code> , <code>inetd.conf(4)</code> , <code>netconfig(4)</code> , <code>attributes(5)</code> , <code>ip6(7P)</code> Sollins, K.R., <i>RFC 783, The TFTP Protocol (Revision 2)</i> , Network Information Center, SRI International, Menlo Park, California, June 1981.				

**NAME** in.tnamed, tnamed – DARPA trivial name server

**SYNOPSIS** `/usr/sbin/in.tnamed [-v]`

**DESCRIPTION** in.tnamed is a server that supports the DARPA Name Server Protocol. The name server operates at the port indicated in the “name” service description (see `services(4)`), and is invoked by `inetd(1M)` when a request is made to the name server.

**OPTIONS** `-v` Invoke the daemon in verbose mode.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtnamd

**SEE ALSO** `uucp(1C)`, `inetd(1M)`, `services(4)`, `attributes(5)`

Postel, Jon, *Internet Name Server*, IEN 116, SRI International, Menlo Park, California, August 1979.

**NOTES** The protocol implemented by this program is obsolete. Its use should be phased out in favor of the Internet Domain Name Service (DNS) protocol.

in.uucpd(1M)

<b>NAME</b>	in.uucpd, uucpd – UUCP server												
<b>SYNOPSIS</b>	<code>/usr/sbin/in.uucpd [-n]</code>												
<b>DESCRIPTION</b>	<p>in.uucpd is the server for supporting UUCP connections over networks.</p> <p>in.uucpd is invoked by inetd(1M) when a UUCP connection is established (that is, a connection to the port indicated in the “uucp” service specification) and executes the following protocol. See services(4):</p> <ol style="list-style-type: none"><li>1. The server prompts with <code>login:.</code> The uucico(1M) process at the other end must supply a username.</li><li>2. Unless the username refers to an account without a password, the server then prompts with <code>Password:.</code> The uucico process at the other end must supply the password for that account.</li></ol> <p>If the username is not valid, or is valid but refers to an account that does not have <code>/usr/lib/uucp/uucico</code> as its login shell, or if the password is not the correct password for that account, the connection is dropped. Otherwise, uucico is run, with the user ID, group ID, group set, and home directory for that account, with the environment variables <code>USER</code> and <code>LOGNAME</code> set to the specified username, and with a <code>-u</code> flag specifying the username. Unless the <code>-n</code> flag is specified, entries are made in <code>/var/adm/utmpx</code>, <code>/var/adm/wtmpx</code>, and <code>/var/adm/lastlog</code> for the username. in.uucpd must be invoked by a user with appropriate privilege (usually root) in order to be able to verify that the password is correct.</p>												
<b>SECURITY</b>	<p>in.uucpd uses pam(3PAM) for authentication, account management, and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for in.uucpd. Here is a partial pam.conf file with entries for uucp using the UNIX authentication, account management, and session management module.</p> <table><tr><td>uucp</td><td>auth</td><td>required</td><td>/usr/lib/security/pam_unix.so.1</td></tr><tr><td>uucp</td><td>account</td><td>required</td><td>/usr/lib/security/pam_unix.so.1</td></tr><tr><td>uucp</td><td>session</td><td>required</td><td>/usr/lib/security/pam_unix.so.1</td></tr></table> <p>If there are no entries for the uucp service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the peer may be prompted for multiple passwords.</p>	uucp	auth	required	/usr/lib/security/pam_unix.so.1	uucp	account	required	/usr/lib/security/pam_unix.so.1	uucp	session	required	/usr/lib/security/pam_unix.so.1
uucp	auth	required	/usr/lib/security/pam_unix.so.1										
uucp	account	required	/usr/lib/security/pam_unix.so.1										
uucp	session	required	/usr/lib/security/pam_unix.so.1

**DIAGNOSTICS** All diagnostic messages are returned on the connection, after which the connection is closed.

<code>user read</code>	An error occurred while reading the username.
<code>passwd read</code>	An error occurred while reading the password.
<code>Login incorrect.</code>	The username is invalid or refers to an account with a login shell other than <code>/usr/lib/uucp/uucico</code> , or the password is not the correct password for the account.

## iostat(1M)

<b>NAME</b>	iostat – report I/O statistics
<b>SYNOPSIS</b>	<code>/usr/bin/iostat [-cCdDeEiImMnpPrstxz] [-l <i>n</i>] [-T u   d] [<i>disk...</i>] [<i>interval</i> [<i>count</i>]]</code>
<b>DESCRIPTION</b>	<p>The <code>iostat</code> utility iteratively reports terminal, disk, and tape I/O activity, as well as CPU utilization. The first line of output is for all time since boot; each subsequent line is for the prior interval only.</p> <p>To compute this information, the kernel maintains a number of counters. For each disk, the kernel counts reads, writes, bytes read, and bytes written. The kernel also takes hi-res time stamps at queue entry and exit points, which allows it to keep track of the residence time and cumulative residence-length product for each queue. Using these values, <code>iostat</code> produces highly accurate measures of throughput, utilization, queue lengths, transaction rates and service time. For terminals collectively, the kernel simply counts the number of input and output characters.</p> <p>During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. <code>iostat</code> reports this as one or more of the following messages:</p> <pre><i>device_name</i> added <i>device_name</i> removed <i>NFS_filesystem</i> mounted <i>NFS_filesystem</i> unmounted cpu[s] taken offline: <i>cpuid</i> cpu[s] brought online: <i>cpuid</i></pre> <p>where <i>device_name</i>, <i>NFS_filesystem</i> and <i>cpuid</i> are replaced with the actual name or names of the entities formatted according to other options.</p> <p>For more general system statistics, use <code>sar(1)</code>, <code>sar(1M)</code>, or <code>vmstat(1M)</code>.</p>
<b>OPTIONS</b>	<p>The <code>iostat</code> utility's activity class options default to <code>t d c</code> (terminal, disk, and CPU). If any activity class options are specified, the default is completely overridden. Therefore, if only <code>-d</code> is specified, neither terminal nor CPU statistics will be reported. The last disk option specified (<code>-d</code>, <code>-D</code>, or <code>-x</code>) is the only one that is used.</p> <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-c</code> Report the percentage of time the system has spent in user mode, in system mode, waiting for I/O, and idling.</li><li><code>-C</code> When the <code>-n</code> and <code>-x</code> options are also selected, report extended disk statistics aggregated by <i>controller id</i>.</li><li><code>-d</code> For each disk, report the number of kilobytes transferred per second, the number of transfers per second, and the average service time in milliseconds.</li></ul>

- D For each disk, report the reads per second, writes per second, and percentage disk utilization.
- e Display device error summary statistics. The total errors, hard errors, soft errors, and transport errors are displayed.
- E Display all device error statistics.
- i In -E output, display the "Device Id" instead of the "Serial No". The "Device Id" is a unique identifier registered by a driver through `ddi_devid_register(9F)`.
- I Report the counts in each interval, rather than rates (where applicable).
- l *n* Limit the number of disks included in the report to *n*; the disk limit defaults to 4 for -d and -D, and unlimited for -x. Note: disks explicitly requested (see *disk* below) are not subject to this disk limit.
- m Report file system mount points. This option is most useful if the -P or -p option is also specified.
- M Display data throughput in MB/sec instead of KB/sec.
- n Display names in descriptive format (for example, `cXtYdZ`, `rmt/N`, `server:/export/path`).
- p For each disk, report per-partition statistics in addition to per-device statistics.
- P For each disk, report per-partition statistics only, no per-device statistics.
- r Display data in a comma-separated format.
- s Suppress messages related to "state changes."
- t Report the number of characters read and written to terminals per second.
- T u | d Display a time stamp.  
  
Specify u for a printed representation of the internal representation of time. See `time(2)`. Specify d for standard date format. See `ctime(3C)`.
- x For each disk, report extended disk statistics. The output is in tabular form.
- z Do not print lines whose underlying data values are all zeroes.

**OPERANDS** The following operands are supported:

iostat(1M)

*disk* Explicitly specify the disks to be reported; in addition to any explicit disks, any active disks up to the disk limit (see -l above) will also be reported.

*count* Display only *count* reports.

*interval* Report once each *interval* seconds.

**EXAMPLES**

**EXAMPLE 1** Using the *iostat* command

```
example% iostat -xtc 5 2
 extended device statistics
device r/s w/s kr/s kw/s wait actv svc_t %w %b tin tout us sy wt id
sd0 0.4 0.3 10.4 8.0 0.0 0.0 36.9 0 1 0 10 0 0 1 99
sd1 0.0 0.0 0.3 0.4 0.0 0.0 35.0 0 0
sd6 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
nfs1 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
nfs2 0.0 0.0 0.0 0.1 0.0 0.0 35.6 0 0
 extended device statistics
device r/s w/s kr/s kw/s wait actv svc_t %w %b tin tout us sy wt id
sd0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0 0 155 0 0 0 100
sd1 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
sd6 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
nfs1 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
nfs2 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
```

*device* name of the disk

*r/s* reads per second

*w/s* writes per second

*Kr/s* kilobytes read per second

*Kw/s* kilobytes written per second

*wait* average number of transactions waiting for service (queue length)

*actv* average number of transactions actively being serviced (removed from the queue but not yet completed)

*svc\_t* average service time, in milliseconds

*%w* percent of time there are transactions waiting for service (queue non-empty)

*%b* percent of time the disk is busy (transactions in progress)

**EXAMPLE 2** Using the *iostat* command

```
example% iostat -xnp
 extended device statistics
r/s w/s kr/s kw/s wait actv wsvc_t asvc_t %w %b device
0.4 0.3 10.4 7.9 0.0 0.0 0.0 36.9 0 1 c0t0d0
0.3 0.3 9.0 7.3 0.0 0.0 0.0 37.2 0 1 c0t0d0s0
```

**EXAMPLE 2** Using the `iostat` command *(Continued)*

```
0.0 0.0 0.1 0.5 0.0 0.0 0.0 34.0 0 0 c0t0d0s1
0.0 0.0 0.0 0.1 0.0 0.0 0.6 35.0 0 0 expositor:/export/home3/user3
```

The fields have the same meanings as in the previous example, with the following additions:

`wsvc_t`                                    average service time in wait queue, in milliseconds  
`asvc_t`                                    average service time active transactions, in milliseconds

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

*System Administration Guide: Basic Administration*

**NOTES** The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

## ipsecconf(1M)

<b>NAME</b>	ipsecconf – configure system wide IPsec policy
<b>SYNOPSIS</b>	<pre><b>/usr/sbin/ipsecconf</b> <b>/usr/sbin/ipsecconf -a file [-q]</b> <b>/usr/sbin/ipsecconf -d index</b> <b>/usr/sbin/ipsecconf -f</b> <b>/usr/sbin/ipsecconf -l [-n]</b></pre>
<b>DESCRIPTION</b>	<p>The <code>ipsecconf</code> utility configures the IPsec policy for a host. Once the policy is configured, all outbound and inbound datagrams are subject to policy checks as they exit and enter the host. If no entry is found, no policy checks will be completed, and all the traffic will pass through. Datagrams that are being forwarded will not be subjected to policy checks that are added using this command. See <code>ifconfig(1M)</code> and <code>tun(7M)</code> for information on how to protect forwarded packets. Depending upon the match of the policy entry, a specific action will be taken.</p> <p>This command can be run only by superuser.</p> <p>Each entry can protect traffic in either one direction (requiring a pair of entries) or by a single policy entry which installs the needed symmetric <code>sadb</code> rules.</p> <p>When the command is issued without any arguments, the list of (file policy entries) loaded are shown. To display the (<code>spd p . e . s</code>) use the <code>-l</code> option. Both will display the index number for the entry.</p> <p>Note, since one file policy entry (FPE) can generate multiple SPD pol entries (SPEs), the list of FPEs may not show all the actual entries. However, it is still useful in determining what what rules have been added to get the spd into its current state.</p> <p>You can use the <code>-d</code> option with the index to delete a given policy in the system. If the <code>-d</code> option removes an FPE entry that produces multiple SPEs, only then SPD with the same policy index as the FPE will be removed. This can produce a situation where there may be SPEs when there are no FPEs</p> <p>With no options, the entries are displayed in the order that they were added, which is not necessarily the order that the traffic match will take place.</p> <p>To view the order in which the traffic match will take place, use the <code>-l</code> option. The rules are ordered such that all bypass rules are checked first, then ESP rules, then AH rules. After that, they are checked in the order entered.</p> <p>Policy entries are not preserved across reboot. Thus the policy needs to be added everytime the machine reboots. To configure policies early in the boot, one can setup policies in the <code>/etc/inet/ipsecinit.conf</code> file, which are then read from the <code>inetinit</code> startup script.</p> <p>See SECURITY for issues in securing this file.</p>

**OPTIONS**

ipseccnf supports the following option:

- a *file*            Add the IPsec policy to the system as specified by each entry in the file. An IPsec configuration file contains one or more entries that specify the configuration. Once the policy is added, all outbound and inbound datagrams are subject to policy checks.  
  
                       Entries in the files are described in the OPERANDS section below. Examples can be found in the EXAMPLES section below.  
  
                       Policy is latched for TCP/UDP sockets on which a connect(3SOCKET) or accept(3SOCKET) is issued. So, the addition of new policy entries may not affect such endpoints or sockets. However, the policy will be latched for a socket with an existing non-null policy. Thus, make sure that there are no preexisting connections that will be subject to checks by the new policy entries.  
  
                       The feature of policy latching explained above may change in the future. It is not advisable to depend upon this feature.
- d *index*            Delete the policy denoted by the index. The index is obtained by invoking ipseccnf without any arguments, or with the -l option. See DESCRIPTION for more information. Once the entry is deleted, all outbound and inbound datagrams affected by this policy entry will not be subjected to policy checks. Be advised that with connections for which the policy has been latched, packets will continue to go out with the same policy, even if it has been deleted. It is advisable to use the -l option to find the correct policy index.
- f                    Flush all the policies in the system. Constraints are similar to the -d option with respect to latching.
- l                    Listing of the internal system policy table. When ipseccnf is invoked without any arguments, a complete list of policy entries with indexes added by the user since boot is displayed. The current table can differ from the previous one if, for example, a multi-homed entry was added or policy reordering occurred, or if a single rule entry generates two spd rules. In the case of a multi-homed entry, all the addresses are listed explicitly. If a mask was not specified earlier but was instead inferred from the address, it will be explicitly listed here. This option is used to view policy entries in the correct order. The outbound and inbound policy entries are listed separately.
- n                    Show network addresses, ports, protocols in numbers. The -n option may only be used with the -l option.

## ipsecconf(1M)

`-q` Quiet mode. Suppresses the warning message generated when adding policies.

**OPERANDS** Each policy entry contains 3 parts specified as follows:

```
{pattern} action {properties}
```

or

```
{pattern} action {properties} ["or" action {properties}]*
```

Every policy entry begins on a new line and can span multiple lines. *pattern* specifies the traffic pattern that should be matched against the outbound and inbound datagrams. If there is a match, a specific *action* determined by the second argument will be taken, depending upon the *properties* of the policy entry.

If there is an `or` in the rule (multiple action-properties for a given pattern), a transmitter will use the first action-property pair that works, while a receiver will use any that are acceptable.

*pattern* and *properties* are name-value pairs where name and value are separated by a `<space>`, `<tab>` or `<newline>`. Multiple name-value pairs should be separated by `<space>`, `<tab>` or `<newline>`. The beginning and end of the pattern and properties are marked by `{` and `}` respectively.

Files can contain multiple policy entries. An unspecified name-value pair in the *pattern* will be considered as a wildcard. Wildcard entries match any corresponding entry in the datagram.

One thing to remember is that UDP port 500 is always bypassed regardless of any policy entries. This is a requirement for `in.iked(1M)` to work.

File can be commented by using a `#` as the first character. Comments may be inserted either at the beginning or the end of a line.

The complete syntax of a policy entry is:

```
policy ::= { <pattern1> } <action1> { <properties1> } |
 { <pattern2> } <action2> { <properties2> }
 ['or' <action2> { <properties2> }]*

pattern1 ::= <pattern_name_value_pair1>*

pattern2 ::= <pattern_name_value_pair2>*

action1 ::= apply | permit | bypass | pass
action2 ::= bypass | pass | drop | ipsec

properties1 ::= {<prop_name_value_pair1>}
properties2 ::= {<prop_name_value_pair2>}

pattern_name_value_pair1 ::=
```

```

saddr <address>/<prefix> |
src <address>/<prefix> |
srcaddr <address>/<prefix> |
smask <mask> |
sport <port> |
daddr <address>/<prefix> |
dst <address>/<prefix> |
dstaddr <address>/<prefix> |
dmask <mask> |
dport <port> |
ulp <protocol> |
proto <protocol>

pattern_name_value_pair2 ::=
 raddr <address>/<prefix> |
 remote <address>/<prefix> |
 rport <port> |
 laddr <address>/<prefix> |
 local <address>/<prefix> |
 lport <port> |
 ulp <protocol> |
 proto <protocol> |
 dir <dir_val2>

address ::= <IPv4 dot notation> | <IPv6 colon notation> |
 <String recognized by gethostbyname>|
 <String recognized by getnetbyname>

prefix ::= <number>

mask ::= <0xhexdigit [hexdigit]> | <0Xhexdigit [hexdigit]> |
 <IPv4 dot notation>

port ::= <number>| <String recognized by getservbyname>

protocol ::= <number>| <String recognized by getprotobyname>

prop_name_value_pair1 ::=
 auth_algs <auth_alg> |
 encr_algs <encr_alg> |
 encr_auth_algs <auth_alg> |
 sa <sa_val> |
 dir <dir_val1>

prop_name_value_pair2 ::=
 auth_algs <auth_alg> |
 encr_algs <encr_alg> |
 encr_auth_algs <auth_alg> |
 sa <sa_val>

auth_alg ::= <auth_alname> ['(' <keylen> ')']
auth_alname ::= any | md5 | hmac-md5 | sha | sha1 | hmac-sha |
 hmac-sha1 | <number>

encr_alg ::= <encr_alname> ['(' <keylen> ')']
encr_alname ::= any | aes | aes-cbc | des | des-cbc | 3des |
 3des-cbc | blowfish | blowfish-cbc | <number>

```

## ipsecconf(1M)

```
keylen ::= <number> | <number>'..' | '..'<number> | <number>'..'<number>

sa_val ::= shared | unique

dir_val1 ::= out | in
dir_val2 ::= out | in | both

number ::= < 0 | 1 | 2 ... 9> <number>
```

Policy entries may contain the following (name value) pairs in the *pattern* field. Each (name value) pair may appear only once in given policy entry.

laddr/plen  
local/plen

The value that follows is the local address of the datagram with the prefix length. Only *plen* leading bits of the source address of the packet will be matched. *plen* is optional. Local means destination on incoming and source on outgoing packets. The source address value can be a hostname as described in `getaddrinfo(3XSOCKET)` or a network name as described in `getnetbyname(3XNET)` or a host address or network address in the Internet standard dot notation. See `inet_addr(3XNET)`. If a hostname is given and `getaddrinfo(3XSOCKET)` returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

raddr/plen  
remote/plen

The value that follows is the remote address of the datagram with the prefix length. Only *plen* leading bits of the remote address of the packet will be matched. *plen* is optional. Remote means source on incoming packets and destination on outgoing packets. The remote address value can be a hostname as described in `getaddrinfo(3SOCKET)` or a network name as described in `getnetbyname(3XNET)` or a host address or network address in the Internet standard dot notation. See `inet_addr(3XNET)`. If a hostname is given and `getaddrinfo(3SOCKET)` returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

src/plen  
srcaddr/plen  
saddr/plen

The value that follows is the source address of the datagram with the prefix length. Only *plen* leading bits of the source address of the packet will be matched. *plen* is optional.

The source address value can be a hostname as described in `getaddrinfo(3XSOCKET)` or a network name as described in `getnetbyname(3XNET)` or a host address or network address in the Internet standard dot notation. See `inet_addr(3XNET)`.

	<p>If a hostname is given and <code>getaddrinfo(3XSOCKET)</code> returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.</p>
<code>daddr/plen</code> <code>dest/plen</code> <code>dstaddr/plen</code>	<p>The value that follows is the destination address of the datagram with the prefix length. Only <i>plen</i> leading bits of the destination address of the packet will be matched. <i>plen</i> is optional.</p> <p>See <i>saddr</i> for valid values that can be given. If multiple source and destination addresses are found, then a policy entry that covers each source address-destination address pair will be added to the system.</p>
<i>smask</i>	<p>For IPv4 only. The value that follows is the source mask. If prefix length is given with <i>saddr</i>, this should not be given. This can be represented either in hexadecimal number with a leading 0x or 0X, for example, 0xffff0000, 0xffff0000 or in the Internet decimal dot notation, for example, 255.255.0.0 and 255.255.255.0. The mask should be contiguous and the behavior is not defined for non-contiguous masks.</p> <p><i>smask</i> is considered only when <i>saddr</i> is given.</p> <p>For both IPv4 and IPv6 addresses, the same information can be specified as a <i>slen</i> value attached to the <i>saddr</i> parameter.</p>
<i>dmask</i>	Analogous to <i>smask</i> .
<code>lport</code>	The value that follows is the local port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in <code>getservbyname(3XNET)</code>
<code>dport</code>	The value that follows is the destination port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in <code>getservbyname(3XNET)</code>
<i>sport</i>	The value that follows is the source port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in <code>getservbyname(3XNET)</code>
<i>dport</i>	The value that follows is the destination port of the datagram. This can be either a port number or a string as described in <code>getservbyname(3XNET)</code> searched with NULL proto argument.
<code>proto</code> <i>ulp</i>	The value that follows is the Upper Layer Protocol that this entry should be matched against. It could be a number or a string as described in <code>getprotobyname(3XNET)</code> If no <i>smask</i> or <i>plen</i> is specified, a <i>plen</i> of 32 for IPv4 or 128 for IPv6 will be used.

## ipsecconf(1M)

If no `smask` or `plen` is specified, a `plen` of 32 for IPv4 or 128 for IPv6 will be used, meaning a host.

Policy entries may contain the following (name value) pairs in the properties field. Each (name value) pair may appear only once in a given policy entry.

`auth_algs` An acceptable value following this implies that IPsec AH header will be present in the outbound datagram. Values following this describe the authentication algorithms that will be used while applying the IPsec AH on outbound datagrams and verified to be present on inbound datagrams. See *RFC 2402*.

This entry can contain either a string or a decimal number.

`string` This should be either MD5 or HMAC-MD5 denoting the HMAC-MD5 algorithm as described in *RFC 2403*, and SHA1, or HMAC-SHA1 or SHA or HMAC-SHA denoting the HMAC-SHA algorithm described in *RFC 2404*. The string can also be ANY, which denotes no-preference for the algorithm. Default algorithms will be chosen based upon the SAs available at this time for manual SAs and the key negotiating daemon for automatic SAs. Strings are not case-sensitive.

`number` A number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

If `auth_algs` is not present, the AH header will not be present in the outbound datagram, and the same will be verified for the inbound datagram.

`encr_algs` An acceptable value following this implies that IPsec ESP header will be present in the outbound datagram. The value following this describes the encryption algorithms that will be used to apply the IPsec ESP protocol to outbound datagrams and verify it to be present on inbound datagrams. See *RFC 2406*.

This entry can contain either a string or a decimal number. Strings are not case-sensitive.

`string` This should be either MD5 or HMAC-MD5 denoting the HMAC-MD5 algorithm as described in *RFC 2403*, and SHA1, or HMAC-SHA1 or SHA or HMAC-SHA denoting the HMAC-SHA algorithm described in *RFC 2404*. The string can also be ANY, which denotes no-preference for the algorithm. Default

	algorithms will be chosen based upon the SAs available at this time for manual SAs and the key negotiating daemon for automatic SAs. Strings are not case-sensitive.
number	A decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.
encr_auth_algs	An acceptable value following encr_auth_algs implies that the IPsec ESP header will be present in the outbound datagram. The values following encr_auth_algs describe the authentication algorithms that will be used while applying the IPsec ESP protocol on outbound datagrams and verified to be present on inbound datagrams. See <i>RFC 2406</i> . This entry can contain either a string or a number. Strings are case-insensitive.
string	Valid values are the same as the ones described for auth_algs above.
number	This should be a decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.
	<p>If encr_algs is present and encr_auth_algs is not present in a policy entry, the system will use an ESP SA regardless of whether the SA has an authentication algorithm or not.</p> <p>If encr_algs is not present and encr_auth_algs is present in a policy entry, null encryption will be provided, which is equivalent to encr_algs with NULL, for outbound and inbound datagrams.</p> <p>If both encr_algs and encr_auth_algs are not present in a policy entry, ESP header will not be present for outbound datagrams and the same will be verified for inbound datagrams.</p> <p>If both encr_algs and encr_auth_algs are present in a policy entry, ESP header with integrity checksum will be present on outbound datagrams and the same will be verified for inbound datagrams.</p> <p>For encr_algs, encr_auth_algs, and auth_algs a key length specification may be present. This is either a single value specifying the only valid key length for the algorithm or a range specifying the valid minimum and/or maximum key lengths. Minimum or maximum lengths may be omitted.</p>
dir	Values following this decides whether this entry is for outbound or inbound datagram. Valid values are strings that should be one of the following:

## ipsecconf(1M)

out	This means that this policy entry should be considered only for outbound datagrams.
in	This means that this policy entry should be considered only for inbound datagrams.
both	This means that this policy entry should be considered for both inbound and outbound datagrams

This entry is not needed when the action is "apply", "permit" or "ipsec". But if it is given while the action is "apply" or "permit", it should be "out" or "in" respectively. This is mandatory when the action is "bypass".

sa Values following this decide the attribute of the security association. Value indicates whether a unique security association should be used or any existing SA can be used. If there is a policy requirement, SAs are created dynamically on the first outbound datagram using the key management daemon. Static SAs can be created using `ipseckey(1M)`. The values used here determine whether a new SA will be used/obtained. Valid values are strings that could be one of the following:

unique	Unique Association. A new/unused association will be obtained/used for packets matching this policy entry. If an SA that was previously used by the same 5 tuples, that is, {Source address, Destination address, Source port, Destination Port, Protocol (for example, TCP/UDP)} exists, it will be reused. Thus uniqueness is expressed by the 5 tuples given above. The security association used by the above 5 tuples will not be used by any other socket. For inbound datagrams, uniqueness will not be verified.
shared	Shared association. If an SA exists already for this source-destination pair, it will be used. Otherwise a new SA will be obtained. This is the default.

This is mandatory only for outbound policy entries and should not be given for entries whose action is "bypass". If this entry is not given for inbound entries, for example, when "dir" is in or "action" is permit, it will be assumed to be shared.

Action follows the pattern and should be given before properties. It should be one of the following and this field is mandatory.

<code>ipsec</code>	Use IPsec for the datagram as described by the properties, if the pattern matches the datagram. If <code>ipsec</code> is given without a <code>dir spec</code> , the pattern is matched to incoming and outgoing datagrams.
<code>apply</code>	Apply IPsec to the datagram as described by the properties, if the pattern matches the datagram. If <code>apply</code> is given, the pattern is matched only on the outbound datagram.
<code>permit</code>	Permit the datagram if the pattern matches the incoming datagram and satisfies the constraints described by the properties. If it does not satisfy the properties, discard the datagram. If <code>permit</code> is given, the pattern is matched only for inbound datagrams.
<code>bypass</code> <code>pass</code>	Bypass any policy checks if the pattern matches the datagram. <code>dir</code> in the properties decides whether the check is done on outbound or inbound datagrams. All the <code>bypass</code> entries are checked before checking with any other policy entry in the system. This has the highest precedence over any other entries. <code>dir</code> is the only field that should be present when action is <code>bypass</code> .
<code>drop</code>	Drop any packets that match the pattern.

If the file contains multiple policy entries, for example, they are assumed to be listed in the order in which they are to be applied. In cases of multiple entries matching the outbound and inbound datagram, the first match will be taken. The system will reorder the policy entry, that is, add the new entry before the old entry, only when:

- The level of protection is "stronger" than the old level of protection. Currently, strength is defined as:

AH and ESP > ESP > AH

The standard uses of AH and ESP were what drove this ranking of "stronger". There are flaws with this. ESP can be used either without authentication, which will allow cut-and-paste or replay attacks, or without encryption, which makes it equivalent or slightly weaker than AH. An administrator should take care to use ESP properly. See `ipsecesp(7P)` for more details.

If the new entry has `bypass` as action, `bypass` has the highest precedence. It can be added in any order, and the system will still match all the `bypass` entries before matching any other entries. This is useful for key management daemons which can use this feature to bypass IPsec as it protects its own traffic.

Entries with both AH (`auth_algs` present in the policy entry) and ESP (`encr_auth_algs` or `encr_auth_algs` present in the policy entry) protection are ordered after all the entries with AH and ESP and before any AH-only and ESP-only entries. In all other cases the order specified by the user is not modified, that is, newer entries are added at the end of all the old entries. See EXAMPLES.

A new entry is considered duplicate of the old entry if an old entry matches the same traffic pattern as the new entry. See EXAMPLES for information on duplicates.

## ipsecconf(1M)

**SECURITY** If, for example, the policy file comes over the wire from an NFS mounted file system, an adversary can modify the data contained in the file, thus changing the policy configured on the machine to suit his needs. Administrators should be cautious about transmitting a copy of the policy file over a network.

Policy is latched for TCP/UDP sockets on which a `connect(3SOCKET)` or `accept(3SOCKET)` has been issued. Adding new policy entries will not have any effect on them. This feature of latching may change in the future. It is not advisable to depend upon this feature.

Make sure to set up the policies before starting any communications, as existing connections may be affected by the addition of new policy entries. Similarly, do not change policies in the middle of a communication.

If your source address is a host that can be looked up over the network, and your naming system itself is compromised, then any names used will no longer be trustworthy.

### **EXAMPLES** **EXAMPLE 1** Protecting Outbound TCP Traffic With ESP and the AES Algorithm

The following example specified that any TCP packet from spiderweb to arachnid should be encrypted with AES, and the SA could be a shared one. It does not verify whether or not the inbound traffic is encrypted.

```
#
Protect the outbound TCP traffic between hosts spiderweb
and arachnid with ESP and use AES algorithm.
#
{
 laddr spiderweb
 raddr arachnid
 ulp tcp
 dir out
} ipsec {
 encr_algs AES
}
```

### **EXAMPLE 2** Verifying Whether or Not Inbound Traffic is Encrypted

Example 1 does not verify whether or not the inbound traffic is encrypted. The entry in this example protects inbound traffic:

```
#
Protect the TCP traffic on inbound with ESP/DES from arachnid
to spiderweb
#
{
 laddr spiderweb
 raddr arachnid
 ulp tcp
 dir in
} ipsec {
 encr_algs AES
```

**EXAMPLE 2** Verifying Whether or Not Inbound Traffic is Encrypted (Continued)

```
}

```

sa can be absent for inbound policy entries as it implies that it can be a shared one. Uniqueness is not verified on inbound. Note that in both the above entries, authentication was never specified. This can lead to cut and paste attacks. As mentioned previously, though the authentication is not specified, the system will still use an ESP SA with `encr_auth_alg` specified, if it was found in the SA tables.

**EXAMPLE 3** Protecting All Traffic Between Two Hosts

The following example protects both directions at once:

```
{
 laddr spiderweb
 raddr arachnid
 ulp tcp
} ipsec {
 encr_algs AES
}
```

**EXAMPLE 4** Authenticating All Inbound Traffic to the Telnet Port

This entry specifies that any inbound datagram to telnet port should come in authenticated with the SHA1 algorithm. Otherwise the datagram should not be permitted. Without this entry, traffic destined to port number 23 can come in clear. sa is not specified, which implies that it is shared. This can be done only for inbound entries. You need to have an equivalent entry to protect outbound traffic so that the outbound traffic is authenticated as well, remove the `dir`.

```
#
All the inbound traffic to the telnet port should be
authenticated.
#
{
 lport telnet
 dir in
} ipsec {
 auth_algs sha1
}
```

**EXAMPLE 5** Verifying Inbound Traffic is Null-Encrypted

The first entry specifies that any packet with address host-B should not be checked against any policies. The second entry specifies that all inbound traffic from network-B should be encrypted with a NULL encryption algorithm and the MD5 authentication algorithm. NULL encryption implies that ESP header will be used without encrypting the datagram. As the first entry is `bypass` it need not be given first in order, as

**EXAMPLE 5** Verifying Inbound Traffic is Null-Encrypted (Continued)

bypass entries have the highest precedence. Thus any inbound traffic will be matched against all bypass entries before any other policy entries.

```
#
Make sure that all inbound traffic from network-B is NULL
encrypted, but bypass for host-B alone from that network.
Add the bypass first.
{
 raddr host-B
 dir in
} bypass {}

Now add for network-B.
{
 raddr network-B/16
 dir in
} ipsec {
 encr_algs NULL
 encr_auth_algs md5
}
```

**EXAMPLE 6** Entries to Bypass Traffic from IPsec

The first two entries provide that any datagram leaving the machine with source port 53 or coming into port number 53 should not be subjected to IPsec policy checks, irrespective of any other policy entry in the system. Thus the latter two entries will be considered only for ports other than port number 53.

```
#
Bypass traffic for port no 53
#
{lport 53} bypass {}
{rport 53} bypass {}
{raddr spiderweb } ipsec {encr_algs any sa unique}
```

**EXAMPLE 7** Protecting Outbound Traffic

```
#
Protect the outbound traffic from all interfaces.
#
{raddr spiderweb dir out} ipsec {auth_algs any sa unique}
```

If the `gethostbyname(3XNET)` call for spiderweb yields multiple addresses, multiple policy entries will be added for all the source address with the same properties.

```
{
 laddr arachnid
 raddr spiderweb
 dir in
} ipsec {auth_algs any sa unique}
```

**EXAMPLE 7** Protecting Outbound Traffic (Continued)

If the `gethostbyname(3XNET)` call for `spiderweb` and the `gethostbyname(3XNET)` call for `arachnid` yield multiple addresses, multiple policy entries will be added for each (`saddr daddr`) pair with the same properties. Use `ipseccnf -l` to view all the policy entries added.

**EXAMPLE 8** Bypassing Unauthenticated Traffic

```
#
Protect all the outbound traffic with ESP except any traffic
to network-b which should be authenticated and bypass anything
to network-c
#
{raddr network-b/16 dir out} ipsec {auth_algs any}
{dir out} ipsec {encr_algs any}
{raddr network-c/16 dir out} bypass {} # NULL properties
```

Note that `bypass` can be given anywhere and it will take precedence over all other entries. `NULL` pattern matches all the traffic.

**EXAMPLE 9** Encrypting IPv6 Traffic with 3DES and MD5

The following entry on the host with the link local address `fe80::a00:20ff:fe21:4483` specifies that any outbound traffic between the hosts with IPv6 link-local addresses `fe80::a00:20ff:fe21:4483` and `fe80::a00:20ff:felf:e346` must be encrypted with 3DES and MD5.

```
{
 laddr fe80::a00:20ff:fe21:4483
 raddr fe80::a00:20ff:felf:e346
 dir out
} ipsec {
 encr_algs 3DES
 encr_auth_algs MD5
}
```

**EXAMPLE 10** Verifying IPv6 Traffic is Authenticated with SHA1

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network `fec0:abcd::0/32` be authenticated with SHA1.

```
{raddr fec0:abcd::0/32} ipsec { auth_algs SHA1 }
```

**EXAMPLE 11** Key Lengths

```
use aes at any key length
{raddr spiderweb} ipsec {encr_algs aes}

use aes with a 192 bit key
{raddr spiderweb} ipsec {encr_algs aes(192)}
```

ipseconf(1M)

**EXAMPLE 11** Key Lengths (Continued)

```
use aes with any key length up to 192 bits
i.e. 192 bits or less
{raddr spiderweb} ipsec {encr_algs aes(..192)}

use aes with any key length of 192 or more
i.e. 192 bits or more
{raddr spiderweb} ipsec {encr_algs aes(192..)}

#use aes with any key from 192 to 256 bits
{raddr spiderweb} ipsec {encr_algs aes(192..256)}

#use any algorithm with a key of 192 bits or longer
{raddr spiderweb} ipsec {encr_algs any(192..)}
```

**EXAMPLE 12** Using “or”

The following entry allows traffic using the AES or Blowfish algorithms from the remote machine spiderweb:

```
{raddr spiderweb} ipsec {encr_algs aes} or {encr_algs blowfish}
```

<b>FILES</b>	/var/run/ipsecpolicy.conf	Cache of IPsec policies currently configured for the system, maintained by ipseconf command. Do not edit this file.
	/etc/inet/ipsecinit.conf	File containing IPsec policies to be installed at the time the system transitions from run-level 2 or 3. If present, these policies are loaded after /usr is mounted but before any non-boot-time routing information is processed and before any Internet services are started, including naming services.
	/etc/inet/ipsecinit.sample	Sample input file for ipseconf.

## DIAGNOSTICS

Bad "string" on line *N*.

Duplicate "string" on line *N*.

*string* refers to one of the names in pattern or properties. A Bad string indicates that an argument is malformed; a Duplicate string indicates that there are multiple arguments of a similar type, for example, multiple Source Address arguments..

Error before or at line *N*.

Indicates parsing error before or at line *N*.

Non-existent index

Reported when the *index* for delete is not a valid one.

spd\_msg return: File exists

Reported when there is already a policy entry that matches the traffic of this new entry.

## ipseckey(1M)

<b>NAME</b>	ipseckey – manually manipulate an IPsec Security Association Database (SADB)						
<b>SYNOPSIS</b>	<pre><b>ipseckey</b> [-nvp] <b>ipseckey</b> [-nvp] -f <i>filename</i> <b>ipseckey</b> [-nvp] [delete   get] SA_TYPE {EXTENSION <i>value...</i>} <b>ipseckey</b> [-np] [monitor   passive_monitor   pmonitor] <b>ipseckey</b> [-nvp] flush {SA_TYPE} <b>ipseckey</b> [-nvp] dump {SA_TYPE} <b>ipseckey</b> [-nvp] save SA_TYPE {<i>filename</i>} <b>ipseckey</b> [-nvp] -s <i>filename</i></pre>						
<b>DESCRIPTION</b>	<p>The ipseckey command is used to manually manipulate the security association databases of the network security services, ipsecak(7P) and ipsecesp(7P). You can use the ipseckey command to set up security associations between communicating parties when automated key management is not available.</p> <p>While the ipseckey utility has only a limited number of general options, it supports a rich command language. The user may specify requests to be delivered by means of a programmatic interface specific for manual keying. See pf_key(7P). When ipseckey is invoked with no arguments, it will enter an interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached. Some commands require an explicit security association (“SA”) type, while others permit the SA type to be unspecified and act on all SA types.</p> <p>ipseckey uses a PF_KEY socket and the message types SADB_ADD, SADB_DELETE, SADB_GET, SADB_UPDATE, SADB_FLUSH, and SADB_X_PROMISC. Thus, you must be a superuser to use this command.</p> <p>ipseckey handles sensitive cryptographic keying information. Please read the SECURITY CONSIDERATIONS section for details on how to use this command securely.</p>						
<b>OPTIONS</b>	<table><tr><td>-f [<i>filename</i>]</td><td>Read commands from an input file, <i>filename</i>. The lines of the input file are identical to the command line language. The load command provides similar functionality. The -s option or the save command can generate files readable by the -f argument.</td></tr><tr><td>-n</td><td>Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.</td></tr><tr><td>-p</td><td>Paranoid. Do not print any keying material, even if saving SAs. Instead of an actual hexadecimal digit, print an X when this flag is turned on.</td></tr></table>	-f [ <i>filename</i> ]	Read commands from an input file, <i>filename</i> . The lines of the input file are identical to the command line language. The load command provides similar functionality. The -s option or the save command can generate files readable by the -f argument.	-n	Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.	-p	Paranoid. Do not print any keying material, even if saving SAs. Instead of an actual hexadecimal digit, print an X when this flag is turned on.
-f [ <i>filename</i> ]	Read commands from an input file, <i>filename</i> . The lines of the input file are identical to the command line language. The load command provides similar functionality. The -s option or the save command can generate files readable by the -f argument.						
-n	Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.						
-p	Paranoid. Do not print any keying material, even if saving SAs. Instead of an actual hexadecimal digit, print an X when this flag is turned on.						

<b>COMMANDS</b>	<p><code>-s [filename]</code>      The opposite of the <code>-f</code> option. If <code>'-'</code> is given for a <i>filename</i>, then the output goes to the standard output. A snapshot of all current SA tables will be output in a form readable by the <code>-f</code> option. The output will be a series of <code>add</code> commands, but with some names not used. This occurs because a single name may often indicate multiple addresses.</p> <p><code>-v</code>                    Verbose. Print the messages being sent into the <code>PF_KEY</code> socket, and print raw seconds values for lifetimes.</p> <p><code>add</code>                    Add an SA. Because it involves the transfer of keying material, it cannot be invoked from the shell, lest the keys be visible in <code>ps(1)</code> output. It can be used either from the interactive <code>ipseckey&gt;</code> prompt or in a command file specified by the <code>-f</code> command. The <code>add</code> command accepts all extension-value pairs described below.</p> <p><code>update</code>                Update SA lifetime, and in the cases of larval SAs (leftover from aborted automated key management), keying material and other extensions. Like <code>add</code>, this command cannot be invoked from the shell because keying material would be seen by the <code>ps(1)</code> command. It can be used either from the interactive <code>ipseckey&gt;</code> prompt or in a command file specified by the <code>-f</code> command. The <code>update</code> command accepts all extension-value pairs, but normally is only used for SA lifetime updates.</p> <p><code>delete</code>                Delete a specific SA from a specific SADB. This command requires the <code>spi</code> extension, and the <code>dest</code> extension for IPsec SAs. Other extension-value pairs are superfluous for a delete message.</p> <p><code>get</code>                    Lookup and display a security association from a specific SADB. Like <code>delete</code>, this command only requires <code>spi</code> and <code>dest</code> for IPsec.</p> <p><code>flush</code>                 Remove all SA for a given <code>SA_TYPE</code>, or all SA for all types.</p> <p><code>monitor</code>              Continuously report on any <code>PF_KEY</code> messages. This uses the <code>SADB_X_PROMISC</code> message to enable messages that a normal <code>PF_KEY</code> socket would not receive to be received. See <code>pf_key(7P)</code>.</p> <p><code>passive_monitor</code>     Like <code>monitor</code>, except that it does not use the <code>SADB_X_PROMISC</code> message.</p> <p><code>pmonitor</code>              Synonym for <code>passive_monitor</code>.</p>
-----------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## ipseckey(1M)

### SECURITY ASSOCIATION TYPES

dump	Will display all SAs for a given SA type, or will display all SAs. Because of the large amount of data generated by this command, there is no guarantee that all SA information will be successfully delivered, or that this command will even complete.
save	Is the command analog of the <code>-s</code> option. It is included as a command to provide a way to snapshot a particular SA type, for example, <code>esp</code> or <code>ah</code> .
help	Prints a brief summary of commands.
all	Specifies all known SA types. This type is only used for the <code>flush</code> and <code>dump</code> commands. This is equivalent to having no SA type for these commands.
ah	Specifies the IPsec Authentication Header (“AH”) SA.
esp	Specifies the IPsec Encapsulating Security Payload (“ESP”) SA.

### EXTENSION VALUE TYPES

Commands like `add`, `delete`, `get`, and `update` require that certain extensions and associated values be specified. The extensions will be listed here, followed by the commands that use them, and the commands that require them. Requirements are currently documented based upon the IPsec definitions of an SA. Required extensions may change in the future. `<number>` can be in either hex (`0xnnn`), decimal (`nnn`) or octal (`0nnn`). `<string>` is a text string. `<hexstr>` is a long hexadecimal number with a bit-length. Extensions are usually paired with values; however, some extensions require two values after them.

`spi <number>`

Specifies the security parameters index of the SA. This extension is required for the `add`, `delete`, `get` and `update` commands.

`replay <number>`

Specifies the replay window size. If not specified, the replay window size is assumed to be zero. It is not recommended that manually added SAs have a replay window. This extension is used by the `add` and `update` commands.

`state <string>|<number>`

Specifies the SA state, either by numeric value or by the strings “larval”, “mature”, “dying” or “dead”. If not specified, the value defaults to mature. This extension is used by the `add` and `update` commands.

`auth_alg <string>|<number>`

`authalg <string>|<number>`

Specifies the authentication algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current authentication algorithms include:

HMAC-MD5           md5, hmac-md5

HMAC-SH-1          sha, sha-1, hmac-sha1, hmac-sha

Often, algorithm names will have several synonyms. This extension is required by the `add` command for certain SA types. It is also used by the `update` command.

```
encr_alg <string>|<number>
```

```
encralg <string>|<number>
```

Specifies the encryption algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current encryption algorithms include DES (“des”), Triple-DES (“3des”), Blowfish (“blowfish”), and AES (“aes”). This extension is required by the `add` command for certain SA types. It is also used by the `update` command.

The next six extensions are lifetime extensions. There are two varieties, “hard” and “soft”. If a hard lifetime expires, the SA will be deleted automatically by the system. If a soft lifetime expires, an `SADB_EXPIRE` message will be transmitted by the system, and its state will be downgraded to `dying` from `mature`. See `pf_key(7P)`. The `monitor` command to `key` allows you to view `SADB_EXPIRE` messages.

```
soft_bytes <number>
```

```
hard_bytes <number>
```

Specifies the number of bytes that this SA can protect. If this extension is not present, the default value is zero, which means that the SA will not expire based on the number of bytes protected. This extension is used by the `add` and `update` commands.

```
soft_addtime <number>
```

```
hard_addtime <number>
```

Specifies the number of seconds that this SA can exist after being added or updated from a larval SA. An update of a mature SA does not reset the initial time that it was added. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the `add` and `update` commands.

```
soft_usetime <number>
```

```
hard_usetime <number>
```

Specifies the number of seconds this SA can exist after first being used. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the `add` and `update` commands.

```
saddr <address|name>
```

```
srcaddr <address|name>
```

```
saddr6 <IPv6 address>
```

```
srcaddr6 <IPv6 address>
```

```
src <address|name>
```

```
src6 <IPv6 address>
```

`srcaddr <address>` and `src <address>` are synonyms that indicate the source address of the SA. If unspecified, the source address will either remain unset, or it will be set to a wildcard address if a destination address was supplied. To not

## ipseckey(1M)

specify the source address is valid for IPsec SAs. Future SA types may alter this assumption. This extension is used by the `add`, `update`, `get` and `delete` commands.

```
daddr <address | name>
dstaddr <address | name>
daddr6 <IPv6 address | name>
dstaddr6 <IPv6 address | name>
dst <addr | name>
dst6 <IPv6 address | name>
```

`dstaddr <addr>` and `dst <addr>` are synonyms that indicate the destination address of the SA. If unspecified, the destination address will remain unset. Because IPsec SAs require a specified destination address and `spi` for identification, this extension, with a specific value, is required for the `add`, `update`, `get` and `delete` commands.

If a name is given, `ipseckey` will attempt to invoke the command on multiple SAs with all of the destination addresses that the name can identify. This is similar to how `ipseccnf` handles addresses.

If `dst6` or `dstaddr6` is specified, only the IPv6 addresses identified by a name are used.

```
proxyaddr <address | name>
proxy <address | name>
```

`proxyaddr <address>` and `proxy <address>` are synonyms that indicate the proxy address for the SA. A proxy address is used for an SA that is protecting an inner protocol header. The proxy address is the source address of the inner protocol's header. This extension is used by the `add` and `update` commands.

```
authkey <hexstring>
```

Specifies the authentication key for this SA. The key is expressed as a string of hexadecimal digits, with an optional `/` at the end, for example, `123/12`. Bits are counted from the most-significant bits down. For example, to express three '1' bits, the proper syntax is the string `"e/3"`. For multi-key algorithms, the string is the concatenation of the multiple keys. This extension is used by the `add` and `update` commands.

```
enckey <hexstring>
```

Specifies the encryption key for this SA. The syntax of the key is the same as `authkey`. A concrete example of a multi-key encryption algorithm is `3des`, which would express itself as a 192-bit key, which is three 64-bit parity-included DES keys. This extension is used by the `add` and `update` commands.

Keying material is very sensitive and should be generated as randomly as possible. Some algorithms have known weak keys. IPsec algorithms have built-in weak key checks, so that if a weak key is in a newly added SA, the `add` command will fail with an invalid value.

Certificate identities are very useful in the context of automated key management, as they tie the SA to the public key certificates used in most automated key management protocols. They are less useful for manually added SAs. Unlike other extensions, `srcidtype` takes two values, a `type`, and an actual `value`. The type can be one of the following:

<code>prefix</code>	An address prefix.
<code>fqdn</code>	A fully-qualified domain name.
<code>domain</code>	Domain name, synonym for <code>fqdn</code> .
<code>user_fqdn</code>	User identity of the form <code>user@fqdn</code> .
<code>mailbox</code>	Synonym for <code>user_fqdn</code> .

The value is an arbitrary text string, which should identify the certificate.

`srcidtype <type, value>`

Specifies a source certificate identity for this SA. This extension is used by the `add` and `update` commands.

`dstidtype <type, value>`

Specifies a destination certificate identity for this SA. This extension is used by the `add` and `update` commands

## SECURITY CONSIDERATIONS

The `ipseckey` command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the `ipseckey` command.

1. Is the TTY going over a network (interactive mode)?
  - If it is, then the security of the keying material is the security of the network path for this TTY's traffic. Using `ipseckey` over a clear-text telnet or rlogin session is risky.
  - Even local windows may be vulnerable to attacks where a concealed program that reads window events is present.
2. Is the file accessed over the network or readable to the world (`-f` option)?
  - A network-mounted file can be sniffed by an adversary as it is being read. A world-readable file with keying material in it is also risky.

If your source address is a host that can be looked up over the network, and your naming system itself is compromised, then any names used will no longer be trustworthy.

Security weaknesses often lie in misapplication of tools, not the tools themselves. Administrators are urged to be cautious when using `ipseckey`. The safest mode of operation is probably on a console, or other hard-connected TTY.

## ipseckey(1M)

For further thoughts on this subject, see the afterward by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C*.

### EXAMPLES

#### EXAMPLE 1 Emptying Out All SAs

To empty out all SA:

```
example# ipseckey flush
```

#### EXAMPLE 2 Flushing Out IPsec AH SAs Only

To flush out only IPsec AH SAs:

```
example# ipseckey flush ah
```

#### EXAMPLE 3 Saving All SAs To Standard Output

To save all SAs to the standard output:

```
example# ipseckey save all
```

#### EXAMPLE 4 Saving ESP SAs To The File /tmp/snapshot

To save ESP SAs to the file /tmp/snapshot:

```
example# ipseckey save esp /tmp/snapshot
```

#### EXAMPLE 5 Deleting an IPsec SA

To delete an IPsec SA, only the SPI and the destination address are needed:

```
example# ipseckey delete esp spi 0x2112 dst 224.0.0.1
```

#### EXAMPLE 6 Getting Information on an IPsec SA

Likewise, getting information on a SA only requires the destination address and SPI:

```
example# ipseckey get ah spi 0x5150 dst mypeer
```

#### EXAMPLE 7 Adding or Updating IPsec SAs

Adding or updating SAs requires entering interactive mode:

```
example# ipseckey
ipseckey> add ah spi 0x90125 src me.domain.com dst you.domain.com \
 authalg md5 authkey 1234567890abcdef1234567890abcdef
ipseckey> update ah spi 0x90125 dst you.domain.com hard_bytes \
 16000000 ipseckey> exit
```

**EXAMPLE 8** Adding an SA in the Opposite Direction

In the case of IPsec, SAs are unidirectional. To communicate securely, a second SA needs to be added in the opposite direction. The peer machine also needs to add both SAs.

```
example# ipseckey
ipseckey> add ah spi 0x2112 src you.domain.com dst me.domain.com \
 authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
 hard_bytes 16000000
ipseckey> exit
```

**EXAMPLE 9** Monitoring PF\_KEY Messages

Monitoring for PF\_KEY messages is straightforward:

```
example# ipseckey monitor
```

**EXAMPLE 10** Using Commands in a File

Commands can be placed in a file that can be parsed with the `-f` option. This file may contain comment lines that begin with the `"#"` symbol. For example:

```
This is a sample file for flushing out the ESP table and
adding a pair of SAs.

flush esp

Watch out! I have keying material in this file. See the
SECURITY CONSIDERATIONS section in this manual page for why this can be
dangerous .

add esp spi 0x2112 src me.domain.com dst you.domain.com \
 authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
 encralg des encrkey be02938e7def2839 hard_usetime 28800
add esp spi 0x5150 src you.domain.com dst me.domain.com \
 authalg md5 authkey 930987dbe09743ade09d92b4097d9e93 \
 encralg des encrkey 8bd4a52e10127deb hard_usetime 28800

End of file - This is a gratuitous comment
```

**EXAMPLE 11** Adding SAs for IPv6 Addresses

The following commands from the interactive-mode create an SA to protect IPv6 traffic between the site-local addresses

```
example # ipseckey
ipseckey> add esp spi 0x6789 src6 fec0:bbbb::4483 dst6 fec0:bbbb::7843
 authalg md5 authkey bde359723576fdea08e56cbe876e24ad
 encralg des encrkey be02938e7def2839 hard_usetime 28800
ipseckey>exit
```

## ipseckey(1M)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

**SEE ALSO** `ps(1)`, `ipseccnf(1M)`, `route(1M)`, `attributes(5)`, `ipsec(7P)`, `ipsecah(7P)`, `ipsecesp(7P)`, `pf_key(7P)`

Schneier, B., *Applied Cryptography: Protocols, Algorithms, and Source Code in C*. Second ed. New York, New York: John Wiley & Sons, 1996.

**DIAGNOSTICS** Parse error on line N.  
If an interactive use of `ipseckey` would print usage information, this would print instead. Usually preceded by another diagnostic.

Unexpected end of command line.  
An additional argument was expected on the command line.

Unknown  
A value for a specific extension was unknown.

Address type N not supported.  
A name-to-address lookup returned an unsupported address family.

is not a bit specifier  
bit length N is too big for  
string is not a hex string  
Keying material was not entered appropriately.

Can only specify single  
A duplicate extension was entered.

Don't use extension for `<string>` for `<command>`.  
An extension not used by a command was used.

One of the entered values is incorrect: Diagnostic code NN: `<msg>`  
This is a general invalid parameter error. The diagnostic code and message provides more detail about what precise value was incorrect and why.

**NOTES** In spite of its IPsec-specific name, `ipseckey` is analogous to `route(1M)`, in that it is a command-line interface to a socket-based administration engine, in this case, `PF_KEY`. `PF_KEY` was originally developed at the United States Naval Research Laboratory.

To have machines communicate securely with manual keying, SAs need to be added by all communicating parties. If two nodes wish to communicate securely, both nodes need the appropriate SAs added.

ipseckey(1M)

In the future ipseckey may be invoked under additional names as other security protocols become available to PF\_KEY.

## kadb(1M)

<b>NAME</b>	kadb – a kernel debugger
<b>SPARC</b>	<b>ok</b> boot <i>device_specifier</i> kadb [-d] [ <i>boot-flags</i> ] > b kadb [-d] [ <i>boot-flags</i> ]
<b>IA</b>	<b>select</b> (b)oot or (i)nterpreter: b kadb [-d] [ <i>boot-flags</i> ] <b>select</b> (b)oot or (i)nterpreter: i kadb [-d] [ <i>boot-flags</i> ]
<b>DESCRIPTION</b>	<p>kadb is an interactive kernel debugger with a user interface similar to adb(1), the assembly language debugger.</p> <p>kadb must be loaded prior to the standalone program it is to debug. kadb runs with the same environment as the standalone program, so it shares many resources with that program. The debugger is cognizant of and able to control multiple processors, should they be present in a system.</p> <p>When kadb is started, it requests the default filename from boot(1M), and if loaded non-interactively (without the -d option), it loads the default filename.</p> <p>On systems which support both 32-bit and 64-bit operating system, boot(1M) chooses an appropriate default filename for that system. If loaded interactively (by specifying the -d option), kadb prompts with the default filename, which can be changed before continuing. The default filename can be specified on the boot(1M) command line. See boot(1M) for details.</p> <p>Before loading the 64-bit kernel explicitly, review the information in boot(1M) for restrictions on running the 64-bit kernel on certain configurations.</p> <p>Unlike adb(1), kadb runs in the same supervisor virtual address space as the program being debugged, although it maintains a separate context. The debugger runs as a <i>co-process</i> that cannot be killed (no :k command as in adb) or rerun (no :r command as in adb). There is no signal control (no :i, :t, or \$i commands as in adb), although the keyboard facilities (CTRL-C, CTRL-S, and CTRL-Q) are simulated.</p> <p>In the case of the UNIX system kernel, the keyboard abort sequence suspends kernel operations and breaks into the debugger. This behavior may be disabled by way of the kbd(1) command and may not be the current default on all systems. See kb(7M) for more information.</p> <p>As the kernel is composed of the core image file and the set of loadable modules already in memory, kadb has the capability of debugging all of these by traversing special data structures. kadb makes use of this feature to allow it to reference any kernel data structure, even if it resides in a loadable module. kadb sets the -d flag by default so the program being debugged can tell it is being watched. If this flag is not given, kadb loads and immediately runs the default kernel.</p> <p>Most adb(1) commands function in kadb as they do in adb. As with adb -k, \$p works when debugging kernels. The verbs ? and / are equivalent in kadb, as there is only one address space in use.</p>

The keyboard abort sequence is L1+A on keyboards with an L1 key, and F1+A on keyboards with no L1 key. On serial lines, the default abort sequence is a BREAK signal, but this can be changed to the sequence “carriage return, tilde, control&hyphen;B” using:

```
kbd -a alternate
```

See kbd(1).

Once aborted, kadb responds with the following:

```
kadb [cpu] :
```

where *cpu* is the number of the CPU on which kadb is currently executing.

**OPTIONS** The following options are supported:

-d Interactive startup. If specified, kadb stops after loading and displays the kadb: prompt, followed by the name of the default program to debug.

The user may either press RETURN to debug the default program, or BACK SPACE followed by the name of another program to debug.

**OPERANDS** The following operands are supported:

*boot-flags* Specifies boot flags as arguments to kadb. The specified boot-flags are passed to the program being debugged. See boot(1M) for available boot-flags.

**SPARC Only** *device-specifier* Specifies the device from which to load. See monitor(1M).

**Kernel Macros** As with adb(1), kernel macros can be used with kadb, but they cannot be read from a file at runtime. Use the kadb \$M command to list all of the built-in kadb macros.

**Commands** kadb reads commands from the standard input and displays responses on the standard output. kadb supports the majority of the adb(1) commands. kadb does not support the following adb commands: :k, :r, :i, :t, or \$i. See adb(1).

Additionally, kadb supports the following commands:

[  
Performs the same function as :e in adb(1), but requires only one keystroke and no RETURN (ENTER on IA based systems).

]  
Performs the same function as :s in adb(1), but requires only one keystroke and no RETURN (ENTER on IA based systems).

## kadb(1M)

**:a**

Sets a hardware access (read or write) breakpoint using the processor hardware facilities. The syntax and action for this command is the same as the **:b** command in `adb`, with the following exceptions:

- The breakpoint triggers if any bytes from the breakpoint for length bytes are being accessed. See §1 below for setting the length of a hardware breakpoint.
- Breakpoints should be aligned for the length specified. Any address is valid for length 1. Addresses divisible by 2 should be used for length 2 (short). Addresses divisible by 4 should be used for length 4 (int).
- Detection of an access breakpoint occurs after completion of the instruction that caused it.
- There are a limited number (4) of hardware breakpoint registers, and, when set, this uses one.
- As this breakpoint does not modify memory locations, this command will work on locations that are not in core at the time the breakpoint is set.

**@fmt**

Used in the same manner as the `adb /` and `?`  commands. Specify `@` as a physical memory address as opposed to the normal virtual address. Specify `fmt` as any of the formats used with the `adb /` command. This command is useful for displaying memory that may not be mapped, for example, `kernel` page tables or buffers used for DMA by device drivers.

**function:: call *arg1, arg2, arg3, ...***

Invokes kernel functions with 0 or more arguments. Using this command results in a response such as:

```
retval = function(arg1,arg2,arg3,...);
```

where *retval* is the return value of the function. This feature can be error prone, as functions may have side effects that cause failures if the kernel is continued.

**:p**

Sets a hardware access (read or write) breakpoint using the processor hardware facilities when an instruction at the specified address is run. The §1 operation has no effect on this type of breakpoint. This breakpoint occurs before the instruction is executed.

**:P**

Works as **:a**, but this command will only breakpoint when an access is made to the address in IA I/O space. See **:a**.

**:w**

Sets a write hardware access breakpoint using the processor hardware facilities.

**[length]§1**

Sets the default data length for an access or write breakpoint. *length* can be set to 1 for byte, 2 for short, and 4 for int word accesses. If *length* is not specified, 1 byte is

assumed. Once set, this value affects any newly set access or write breakpoints, but does not affect ones set before this operation.

\$b

Displays two additional columns that `adb` does not. The first is the `type` column which indicates `soft` for a normal breakpoint, `access` for an access hardware breakpoint, `write` for a write hardware breakpoint, and `inst` for an instruction hardware breakpoint. The second is the `len` column which for access and write breakpoints indicate the length of the operation to break on.

**SPARC**

\$q Gives control to the boot prom, from which you may reboot the system.

`cpu:x` Switches the active CPU to `cpu`. Thereafter, commands such as `$r` and `$c` displays the registers and stack of the new CPU, `cpu`.

**IA**

`port:i` Inputs a byte for display from `port`. `port` is an address-specified I/O port. For example, `330:i` inputs from address port 330.

`port:i8` Same as the `:i` command. See `:i`.

`port:i16` Inputs two bytes for display from `port`. `port` is an address-specified I/O port.

`port:i32` Inputs four bytes for display from `port`. `port` is an address-specified I/O port.

`port,data:o` Outputs a byte to `port`. `port` is an address-specified I/O port. `[address],[data]:o` outputs the value `data` to address I/O `port`. For example, `330,80:o` outputs 80 to address port 330.

`port,data:o8` Same as the `:o` command. See `port,data:o`.

`port,data:o16` Outputs two bytes to `port`. `port` is an address-specified I/O port.

`port,data:o32` Outputs four bytes to `port`. `port` is an address-specified I/O port.

\$q Prompts the user with:

Type 'y' if you really want to reboot. Responding with a y or Y causes the system to reboot. Responding with anything other than a y or Y returns control to `kadb`. Use this feature when you cannot press the `reset` switch on your machine. Because using `$q` may result in data loss, this command should only be used when you would press the `reset` switch or power off your system.

**Online Help  
Commands**

`::help` Displays the formats of `kadb` commands and extended commands.

`::?` Same as the `::help` command. See `::help`.

`::morehelp` Displays additional information about commonly used commands and provides an explanation of data formats.

kadb(1M)

**Scroll Control Feature**

`num::more`

A common problem with using `kadb` is that scrolling is sometimes too fast and that CTRL-s and CTRL-q are inexact controls. A conditional scroll control feature similar to `more(1)` has been added to `kadb`. To enable this feature, the user specifies the number of lines to be displayed, followed by `::more`. For example, the command `14::more` displays 14 (current radix) lines, followed by the `--More--` prompt. At this prompt, press: ENTER or RETURN to display one more line. Press `c`, `C`, or CTRL-c to interrupt the display. Press any other key to display the next `num` number of specified lines (14 in this example). The command `::more` displays the current setting for the number of lines that `kadb` displays before printing the `--More--` prompt. The initial scroll control value of this feature is 0, meaning that scrolling is disabled. Once enabled, the `0::more` command disables the scroll control feature.

**Deferred Breakpoint Feature**

Since the kernel is dynamically loaded, not all modules may be loaded when a breakpoint is set `kadb` can set *deferred* breakpoints which will be dynamically inserted when the corresponding module is loaded. The module and the location must both be specified when referring to a deferred breakpoint, as follows:

```
module_name#location:
```

This syntax is implemented for `kadb` only and uses existing breakpoint commands (for example, `ufs#ufs_open:b` or `ufs#ufs_open+4,5:b`).

If the module has been loaded, `kadb` attempts to find the symbol in the module specified. If `kadb` finds the symbol, it sets a regular breakpoint. If it does not find the symbol, it generates an error message and returns to the command line without setting a breakpoint.

If `kadb` fails to find the module on the list of currently loaded modules, it does not resolve the `location`. Instead, it sends a message to the user and sets a deferred breakpoint.

When the specified module is loaded, `kadb` tries to resolve the location. If the location can be resolved, the deferred breakpoint is converted to a regular breakpoint. If `kadb` cannot resolve the location, a message is sent to the user, and `kadb` halts execution. In this case, `kadb` does not convert the deferred breakpoint to a regular breakpoint; it removes it from the breakpoint table. The user may then re-enter a correct breakpoint. Strict scoping is enforced, so `kadb` does not look at any other module than the one specified with the location.

When specifying a deferred breakpoint in which the module name contains a hyphen, you must escape the hyphen. For example, for a module named `pci-ide`, enter:

```
pci\-ide#_init:b
```

The output from the the `$b` command indicates whether the breakpoint is of type "deferred" (`defer`) or is another type.

**FILES**

- `/platform/platform-name/kadb`  
primary debugger path
- `/platform/hardware-class-name/kadb`  
alternative debugger path for some platforms
- `/platform/platform-name/kernel/unix`  
primary default 32-bit kernel
- `/platform/hardware-class-name/kernel/unix`  
alternative default 32-bit kernel for some platforms

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcar

**SEE ALSO** `adb(1)`, `more(1)`, `uname(1)`, `boot(1M)`, `kernel(1M)`, `attributes(5)`, `kb(7M)`

**SPARC Only** `kbd(1)`, `monitor(1M)`, `obpsym(1M)`

**DIAGNOSTICS** When there is no current command or format, `kadb` comments about syntax errors, abnormal termination of commands, and the like.

**SPARC Only** On a SPARC based system, `kadb` cannot reliably single-step over instructions which change the processor status register.

**SPARC and IA** If a breakpoint or watchpoint is triggered while the console frame buffer is powered off, the system can crash and be left in a state from which it is difficult to recover. If one of these is triggered while the monitor is powered off, you will not be able to see the debugger output.

**NOTES** `platform-name` can be found using the `-i` option of `uname(1)`. `hardware-class-name` can be found using the `-m` option of `uname(1)`.

## kadmin(1M)

<b>NAME</b>	kadmin, kadmin.local – Kerberos database administration program
<b>SYNOPSIS</b>	<pre><b>/usr/sbin/kadmin</b> [-r <i>realm</i>] [-p <i>principal</i>] [-q <i>query</i>] [-s <i>admin_server</i> [:<i>port</i>]] [ [-c <i>credential_cache</i>]   [-k [-t <i>keytab</i>]]   [-w <i>password</i>]]  <b>/usr/sbin/kadmin.local</b> [-r <i>realm</i>] [-p <i>principal</i>] [-q <i>query</i>] [-d <i>dbname</i>] [-e "<i>enc:salt...</i>"] [-m] [-D]</pre>
<b>DESCRIPTION</b>	<p>kadmin and kadmin.local are interactive command-line interfaces to the Kerberos V5 administration system. They provide for the maintenance of Kerberos principals, policies, and service key tables (keytabs). kadmin and kadmin.local provide identical functionality; the difference is that kadmin.local can run only on the master KDC and does not use Kerberos authentication. Except as explicitly noted otherwise, this man page will use kadmin to refer to both versions.</p> <p>By default, both versions of kadmin attempt to determine your user name and perform operations on behalf of your "<i>username/admin</i>" instance. Operations performed are subject to privileges granted or denied to this user instance by the Kerberos ACL file (see <code>kadm5.ac1(4)</code>). You may perform administration as another user instance by using the <code>-p</code> option.</p> <p>The remote version, kadmin, uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network. It normally prompts for a password and authenticates the user to the Kerberos administration server, <code>kadmin.d</code>, whose service principal is <code>kadmin/admin</code>. Some options specific to the remote version permit the password prompt to be bypassed. The <code>-c</code> option searches the named credentials cache for a valid ticket for the <code>kadmin/admin</code> service and uses it to authenticate the user to the Kerberos admin server without a password. The <code>-k</code> option searches a keytab for a credential to authenticate to the <code>kadmin/admin</code> service, and again no password is collected. If kadmin has collected a password, it requests a <code>kadmin/admin</code> Kerberos service ticket from the KDC, and uses that service ticket to interact with <code>kadmin.d</code>.</p> <p>The local version, kadmin.local, must be run with an effective UID of root, and normally uses a key from the <code>/var/krb5/.k5.realm</code> stash file (see <code>kdb5_util(1M)</code>) to decrypt information from the database rather than prompting for a password. The <code>-m</code> option will bypass the <code>.k5.realm</code> stash file and prompt for the master password.</p>
<b>OPTIONS</b>	<p><code>-r <i>realm</i></code> Use <i>realm</i> as the default database realm.</p> <p><code>-p <i>principal</i></code> Authenticate <i>principal</i> to the <code>kadmin/admin</code> service. Otherwise, kadmin will append <code>/admin</code> to the primary principal name of the default credentials cache, the value of the <code>USER</code> environment variable, or the username as obtained with <code>getpwuid</code>, in that order of preference.</p> <p><code>-k [ -t <i>keytab</i>]</code> Use the default keytab (<code>-k</code>) or a specific keytab ( <code>-t <i>keytab</i></code>) to decrypt the KDC response instead of prompting for a password. In this case, the default principal will be <code>host/hostname</code>. This is primarily used for keytab maintenance.</p>

- c *credentials\_cache*  
Search *credentials\_cache* for a service ticket for the *kadmin/admin* service; it can be acquired with the *kinit(1)* program. If this option is not specified, *kadmin* requests a new service ticket from the KDC, and stores it in its own temporary credentials cache.
  - w *password*  
Use *password* instead of prompting for one. Note that placing the password for a Kerberos principal with administration access into a shell script can be dangerous if unauthorized users gain read access to the script or can read arguments of this command through *ps(1)*.
  - q *query*  
Pass *query* directly to *kadmin*, which will perform *query* and then exit. This can be useful for writing scripts.
  - s *admin\_server[:port]*  
Administer the specified admin server at the specified port number (*port*). This can be useful in administering a realm not known to your client.
  - d *dbname*  
Specify a non-standard database name. [Local only]
  - e "*enc:salt ...*"  
Specify a different encryption type and/or key salt. [Local only]
  - m  
Accept the database master password from the keyboard rather than using the */var/krb5/.k5.realm* stash file. [Local only]
  - D  
Turn on debug mode. [Local only]
- COMMANDS**
- list\_requests*  
Lists all the commands available for *kadmin*. Aliased by *lr* and *?*.
  - get\_privs*  
Lists the current Kerberos administration privileges (ACLs) for the principal that is currently running *kadmin*. The privileges are based on the */etc/krb5/kadm5.acl* file on the master KDC. Aliased by *getprivs*.
  - add\_principal [options] newprinc*  
Creates a new principal, *newprinc*, prompting twice for a password. If the *-policy* option is not specified and a policy named *default* exists, then the *default* policy is assigned to the principal; note that the assignment of the *default* policy occurs automatically only when a principal is first created, so the *default* policy must already exist for the assignment to occur. The automatic assignment of the *default* policy can be suppressed with the *-clearpolicy* option. This command requires the *add* privilege. Aliased by *addprinc* and *ank*. The options are:

- expire *expdate*  
Expiration date of the principal. See the Time Formats section for the valid absolute time formats that you can specify for *expdate*.
- pwexpire *pwexpdate*  
Password expiration date. See the Time Formats section for the valid absolute time formats that you can specify for *pwexpdate*.
- maxlife *maxlife*  
Maximum ticket life for the principal. See the Time Formats section for the valid time duration formats that you can specify for *maxlife*.
- maxrenewlife *maxrenewlife*  
Maximum renewable life of tickets for the principal. See the Time Formats section for the valid time duration formats that you can specify for *maxrenewlife*.
- kvno *kvno*  
Explicitly set the key version number.
- policy *policy*  
Policy used by the principal. If both the `-policy` and `-clearpolicy` options are not specified, the default policy is used if it exists; otherwise, the principal will have no policy. Also note that the password and principal name must be different when you add a new principal with a specific policy or the default policy.
- clearpolicy  
-clearpolicy prevents the default policy from being assigned when `-policy` is not specified. This option has no effect if the default policy does not exist.
- {-|+}allow\_postdated  
-allow\_postdated prohibits the principal from obtaining postdated tickets. (Sets the KRB5\_KDB\_DISALLOW\_POSTDATED flag.) +allow\_postdated clears this flag.
- {-|+}allow\_forwardable  
-allow\_forwardable prohibits the principal from obtaining forwardable tickets. (Sets the KRB5\_KDB\_DISALLOW\_FORWARDABLE flag.) +allow\_forwardable clears this flag.
- {-|+}allow\_renewable  
-allow\_renewable prohibits the principal from obtaining renewable tickets. (Sets the KRB5\_KDB\_DISALLOW\_RENEWABLE flag.) +allow\_renewable clears this flag.
- {-|+}allow\_proxiabile  
-allow\_proxiabile prohibits the principal from obtaining proxiabile tickets. (Sets the KRB5\_KDB\_DISALLOW\_PROXIABLE flag.) +allow\_proxiabile clears this flag.

```

{-|+}allow_dup_skey
 -allow_dup_skey disables user-to-user authentication for the principal by
 prohibiting this principal from obtaining a session key for another user. (Sets the
 KRB5_KDB_DISALLOW_DUP_SKEY flag.) +allow_dup_skey clears this flag.

{-|+}requires_preauth
 +requires_preauth requires the principal to preauthenticate before being
 allowed to kinit. (Sets the KRB5_KDB_REQUIRES_PRE_AUTH flag.)
 -requires_preauth clears this flag.

{-|+}requires_hwauth
 +requires_hwauth requires the principal to preauthenticate using a hardware
 device before being allowed to kinit. (Sets the KRB5_KDB_REQUIRES_HW_AUTH
 flag.) -requires_hwauth clears this flag.

{-|+}allow_svr
 -allow_svr prohibits the issuance of service tickets for the principal. (Sets the
 KRB5_KDB_DISALLOW_SVR flag.) +allow_svr clears this flag.

{-|+}allow_tgs_req
 -allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a
 service ticket for the principal is not permitted. This option is useless for most
 things. +allow_tgs_req clears this flag. The default is +allow_tgs_req. In
 effect, -allow_tgs_req sets the KRB5_KDB_DISALLOW_TGT_BASED flag on
 the principal in the database.

{-|+}allow_tix
 -allow_tix forbids the issuance of any tickets for the principal. +allow_tix
 clears this flag. The default is +allow_tix. In effect, -allow_tix sets the
 KRB5_KDB_DISALLOW_ALL_TIX flag on the principal in the database.

{-|+}needchange
 +needchange sets a flag in attributes field to force a password change;
 -needchange clears it. The default is -needchange. In effect, +needchange
 sets the KRB5_KDB_REQUIRES_PWCHANGE flag on the principal in the database.

{-|+}password_changing_service
 +password_changing_service sets a flag in the attributes field marking this
 as a password change service principal (useless for most things).
 -password_changing_service clears the flag. This flag intentionally has a
 long name. The default is -password_changing_service. In effect,
 +password_changing_service sets the KRB5_KDB_PWCHANGE_SERVICE
 flag on the principal in the database.

-randkey
 Sets the key of the principal to a random value.

-pw password
 Sets the key of the principal to the specified string and does not prompt for a
 password. Note that using this option in a shell script can be dangerous if
 unauthorized users gain read access to the script.

```

**Example:**

```
kadmin: addprinc tlyu/admin
WARNING: no policy specified for "tlyu/admin@ACME.COM";
defaulting to no policy.
Enter password for principal tlyu/admin@ACME.COM:
Re-enter password for principal tlyu/admin@ACME.COM:
Principal "tlyu/admin@ACME.COM" created.
kadmin:
```

**Errors:**

KADM5\_AUTH\_ADD (requires add privilege)

KADM5\_BAD\_MASK (should not happen)

KADM5\_DUP (principal exists already)

KADM5\_UNK\_POLICY (policy does not exist)

KADM5\_PASS\_Q\_\* (password quality violations)

**delete\_principal [-force] *principal***

Deletes the specified principal from the database. This command prompts for deletion, unless the `-force` option is given. This command requires the `delete` privilege. Aliased by `delprinc`.

**Example:**

```
kadmin: delprinc mwm_user
Are you sure you want to delete the principal
"mwm_user@ACME.COM"? (yes/no): yes
Principal "mwm_user@ACME.COM" deleted.
Make sure that you have removed this principal from
all kadmin ACLs before reusing.
kadmin:
```

**Errors:**

KADM5\_AUTH\_DELETE (requires delete privilege)

KADM5\_UNK\_PRINC (principal does not exist)

**modify\_principal [*options*] *principal***

Modifies the specified principal, changing the fields as specified. The options are as above for `add_principal`, except that password changing is forbidden by this command. In addition, the option `-clearpolicy` will clear the current policy of a principal. This command requires the `modify` privilege. Aliased by `modprinc`.

**Errors:**

KADM5\_AUTH\_MODIFY (requires modify privilege)

KADM5\_UNK\_PRINC (principal does not exist)

KADM5\_UNK\_POLICY (policy does not exist)

KADM5\_BAD\_MASK (should not happen)

`change_password` [*options*] *principal*

Changes the password of *principal*. Prompts for a new password if neither `-randkey` or `-pw` is specified. Requires the `changepw` privilege, or that the principal that is running the program to be the same as the one changed. Aliased by `cpw`. The following options are available:

`-randkey`

Sets the key of the principal to a random value.

`-pw password`

Sets the password to the specified string. Not recommended.

Example:

```
kadmin: cpw systest
Enter password for principal systest@ACME.COM:
Re-enter password for principal systest@ACME.COM:
Password for systest@ACME.COM changed.
kadmin:
```

Errors:

KADM5\_AUTH\_MODIFY (requires the `modify` privilege)

KADM5\_UNK\_PRINC (principal does not exist)

KADM5\_PASS\_Q\_\* (password policy violation errors)

KADM5\_PADD\_REUSE (password is in principal's password history)

KADM5\_PASS\_TOOSOON (current password minimum life not expired)

`get_principal` [`-terse`] *principal*

Gets the attributes of *principal*. Requires the `inquire` privilege, or that the principal that is running the program to be the same as the one being listed. With the `-terse` option, outputs fields as quoted tab-separated strings. Aliased by `getprinc`.

Examples:

```
kadmin: getprinc tlyu/admin
Principal: tlyu/admin@ACME.COM
Expiration date: [never]
Last password change: Mon Aug 12 14:16:47 EDT 1996
Password expiration date: [none]
Maximum ticket life: 0 days 10:00:00
Maximum renewable life: 7 days 00:00:00
Last modified: Mon Aug 12 14:16:47 EDT 1996
(example_user/admin@ACME.COM)
Last successful authentication: [never]
Last failed authentication: [never]
Failed password attempts: 0
Number of keys: 2 Key: vno 1, DES cbc mode with CRC-32,
no salt Key: vno 1, DES cbc mode with CRC-32,
Version 4 Attributes:
Policy: [none]
```

## kadmin(1M)

```
kadmin: getprinc -terse systest
systest@ACME.COM 3 86400 604800 1 785926535 753241234
785900000
tlyu/admin@ACME.COM 786100034 0 0
kadmin:
```

### Errors:

KADM5\_AUTH\_GET (requires the get [inquire] privilege)

KADM5\_UNK\_PRINC (principal does not exist)

### list\_principals [*expression*]

Retrieves all or some principal names. *expression* is a shell-style glob expression that can contain the wild-card characters `?`, `*`, and `[]`'s. All principal names matching the expression are printed. If no expression is provided, all principal names are printed. If the expression does not contain an `@` character, an `@` character followed by the local realm is appended to the expression. Requires the `list` privilege. Aliased by `listprincs`, `get_principals`, and `getprincs`.

### Examples:

```
kadmin: listprincs test*
test3@ACME.COM
test2@ACME.COM
test1@ACME.COM
testuser@ACME.COM
kadmin:
```

### add\_policy [*options*] *policy*

Adds the named policy to the policy database. Requires the `add` privilege. Aliased by `addpol`. The following options are available:

#### -maxlife *maxlife*

sets the maximum lifetime of a password. See the `Time Formats` section for the valid time duration formats that you can specify for *maxlife*.

#### -minlife *minlife*

sets the minimum lifetime of a password. See the `Time Formats` section for the valid time duration formats that you can specify for *minlife*.

#### -minlength *length*

sets the minimum length of a password.

#### -minclasses *number*

sets the minimum number of character classes allowed in a password. The valid values are:

- |   |                                             |
|---|---------------------------------------------|
| 1 | only letters (himom)                        |
| 2 | both letters and numbers (hi2mom)           |
| 3 | letters, numbers, and punctuation (hi2mom!) |

#### -history *number*

sets the number of past keys kept for a principal.

**Errors:**

KADM5\_AUTH\_ADD (requires the add privilege)

KADM5\_DUP (policy already exists)

**delete\_policy *policy***

Deletes the named policy. Prompts for confirmation before deletion. The command will fail if the policy is in use by any principals. Requires the delete privilege.

Aliased by delpol.

**Example:**

```
kadmin: del_policy guests
Are you sure you want to delete the
policy "guests"? (yes/no): yes
Policy "guests" deleted.
kadmin:
```

**Errors:**

KADM5\_AUTH\_DELETE (requires the delete privilege)

KADM5\_UNK\_POLICY (policy does not exist)

KADM5\_POLICY\_REF (reference count on policy is not zero)

**modify\_policy [*options*] *policy***

Modifies the named policy. Options are as above for add\_policy. Requires the modify privilege. Aliased by modpol.

**Errors:**

KADM5\_AUTH\_MODIFY (requires the modify privilege)

KADM5\_UNK\_POLICY (policy does not exist)

**get\_policy [-terse] *policy***

Displays the values of the named policy. Requires the inquire privilege. With the -terse flag, outputs the fields as quoted strings separated by tabs. Aliased by getpol.

**Examples:**

```
kadmin: get_policy admin
Policy: admin
Maximum password life: 180 days 00:00:00
Minimum password life: 00:00:00
Minimum password length: 6
Minimum number of password character classes: 2
Number of old keys kept: 5
Reference count: 17
kadmin: get_policy -terse
admin admin 15552000 0 6 2 5 17
kadmin:
```

**Errors:**

KADM5\_AUTH\_GET (requires the get privilege)

KADM5\_UNK\_POLICY (policy does not exist)

**list\_policies** [*expression*]

Retrieves all or some policy names. *expression* is a shell-style glob expression that can contain the wild-card characters `?`, `*`, and `[]`'s. All policy names matching the expression are printed. If no expression is provided, all existing policy names are printed. Requires the `list` privilege. Aliased by `listpols`, `get_policies`, and `getpols`.

Examples:

```
kadmin: listpols
test-pol dict-only once-a-min test-pol-nopw
kadmin: listpols t*
test-pol test-pol-nopw kadmin:
```

**ktadd** [-k *keytab*] [-q] [*principal* | -glob *princ-exp*] [...]

Adds a principal or all principals matching *princ-exp* to a keytab, randomizing each principal's key in the process. Requires the `inquire` and `changepw` privileges. An entry for each of the principal's unique encryption types is added, ignoring multiple keys with the same encryption type but different salt types. If the `-k` argument is not specified, the default keytab file, `/etc/krb5/krb5.keytab`, is used. If the `-q` option is specified, less status information is displayed. Aliased by `xst`. The `-glob` option requires the `list` privilege. Also, note that if you use `-glob` to create a keytab, you need to remove `/etc/krb5/kadm5.keytab` and create it again if you want to use `-p */admin` with `kadmin`.

*princ-exp* follows the same rules described for the `list_principals` command.

Example:

```
kadmin: ktadd -k /tmp/new-keytab nfs/chicago
Entry for principal nfs/chicago with kvno 2,
encryption type DES-CBC-CRC added to keytab
WRFILE:/tmp/new-keytab.
kadmin:
```

**ktremove** [-k *keytab*] [-q] *principal* [*kvno* | `all` | `old`]

Removes entries for the specified principal from a keytab. Requires no privileges, since this does not require database access. If `all` is specified, all entries for that principal are removed; if `old` is specified, all entries for that principal except those with the highest kvno are removed. Otherwise, the value specified is parsed as an integer, and all entries whose kvno match that integer are removed. If the `-k` argument is not specified, the default keytab file, `/etc/krb5/krb5.keytab`, is used. If the `-q` option is specified, less status information is displayed. Aliased by `ktrem`.

Example:

```
kadmin: kremove -k /tmp/new-keytab nfs/chicago
Entry for principal nfs/chicago with kvno 2
removed from keytab
```

```
WRFFILE: /tmp/new-keytab.
kadmin:
```

```
quit
```

Quits kadmin. Aliased by `exit` and `q`.

## Time Formats

Various commands in `kadmin` can take a variety of time formats, specifying time durations or absolute times. The `kadmin` option variables `maxrenewlife`, `maxlife`, and `minlife` are time durations, whereas `expdate` and `pwexpdate` are absolute times.

Examples:

```
kadmin: modprinc -expire "12/31 7pm" jdb
kadmin: modprinc -maxrenewlife "2 fortnight" jdb
kadmin: modprinc -pwexpire "this sunday" jdb
kadmin: modprinc -expire never jdb
kadmin: modprinc -maxlife "7:00:00pm tomorrow" jdb
```

Note that times which do not have the "ago" specifier default to being absolute times, unless they appear in a field where a duration is expected. In that case, the time specifier will be interpreted as relative. Specifying "ago" in a duration can result in unexpected behavior.

The following time formats and units can be combined to specify a time. The time and date format examples are based on the date and time of July 2, 1999, 1:35:30 p.m.

Time Format	Examples
<code>hh[:mm][:ss][am/pm/a.m./p.m.]</code>	1p.m., 1:35, 1:35:30pm

Variable	Description
<code>hh</code>	hour (12-hour clock, leading zero permitted but not required)
<code>mm</code>	minutes
<code>ss</code>	seconds

Date Format	Examples
<code>mm/dd[/yy]</code>	07/02, 07/02/99
<code>yyyy-mm-dd</code>	1999-07-02
<code>dd-month-yyyy</code>	02-July-1999
<code>month [yyyy]</code>	Jul 02, July 02,1999
<code>dd month[ yyyy]</code>	02 JULY, 02 july 1999

kadmin(1M)

Variable Description	
<i>dd</i>	day
<i>mm</i>	month
<i>yy</i>	year within century (00-38 is 2000 to 2038; 70-99 is 1970 to 1999)
<i>yyyy</i>	year including century
<i>month</i>	locale's full or abbreviated month name

  

Time Units	Examples
[+ - #] year	"-2 year"
[+ - #] month	"2 months"
[+ - #] fortnight	
[+ - #] week	
[+ - #] day	
[+ - #] hour	
[+ - #] minute	
[+ - #] min	
[+ - #] second	
[+ - #] sec	
tomorrow	
yesterday	
today	
now	
this	"this year"
last	"last saturday"
next	"next month"
sunday	
monday	
tuesday	
wednesday	
thursday	

friday	
saturday	
never	

You can also use the following time modifiers: first, second, third, fourth, fifth, sixth, seventh, eighth, ninth, tenth, eleventh, twelfth, and ago.

**FILES**

`/var/krb5/principal.db`  
Kerberos principal database.

`/var/krb5/principal.kadm5`  
Kerberos administrative database. Contains policy information.

`/var/krb5/principal.kadm5.lock`  
Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, `kadmin` will exit with an error if this file does *not* exist).

`/var/krb5/kadm5.dict`  
Dictionary of strings explicitly disallowed as passwords.

`/etc/krb5/kadm5.acl`  
List of principals and their `kadmin` administrative privileges.

`/etc/krb5/kadm5.keytab`  
Keytab for `kadmin/admin` principal.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkdcu

**SEE ALSO**

`kpasswd(1)`, `gkadmin(1M)`, `kadmind(1M)`, `kdb5_util(1M)`, `kadm5.acl(4)`, `kdc.conf(4)`, `krb5.conf(4)`, `attributes(5)`, `SEAM(5)`

**HISTORY**

The `kadmin` program was originally written by Tom Yu at MIT, as an interface to the OpenVision Kerberos administration program.

**DIAGNOSTICS**

The `kadmin` command is currently incompatible with the MIT `kadmind` daemon interface, so you cannot use this command to administer an MIT-based Kerberos database. However, SEAM-based Kerberos clients can still use a MIT-based KDC.

## kadmind(1M)

<b>NAME</b>	kadmind – Kerberos administration daemon
<b>SYNOPSIS</b>	<code>/usr/lib/kadmind [-d] [-m] [-p <i>port-number</i>] [-r <i>realm</i>]</code>
<b>DESCRIPTION</b>	<p>kadmind runs on the master key distribution center (KDC), which stores the principal and policy databases. kadmind accepts remote requests to administer the information in these databases. Remote requests are sent, for example, by <code>kpasswd(1)</code>, <code>gkamdin(1M)</code>, and <code>kadmin(1M)</code> commands, all of which are clients of kadmind. When you install a KDC, kadmind is set up in the <code>init</code> scripts to start automatically when the KDC is rebooted.</p> <p>kadmind requires a number of configuration files to be set up for it to work:</p> <p><code>/etc/krb5/kdc.conf</code></p> <p>The KDC configuration file contains configuration information for the KDC and the Kerberos administration system. kadmind understands a number of configuration variables (called relations) in this file, some of which are mandatory and some of which are optional. In particular, kadmind uses the <code>acl_file</code>, <code>dict_file</code>, <code>admin_keytab</code>, and <code>kadmind_port</code> relations in the <code>[realms]</code> section. Refer to the <code>kdc.conf(4)</code> man page for information regarding the format of the KDC configuration file.</p> <p><code>/etc/krb5/kadm5.keytab</code></p> <p>kadmind requires <code>akeytab</code> (key table) containing correct entries for the <code>kadmin/admin</code> and <code>kadmin/changepw</code> principals for every realm that kadmind answers requests. The keytab can be created with the <code>kadmin.local(1M)</code>, <code>kdb5_util(1M)</code> command. The location of the keytab is determined by the <code>admin_keytab</code> relation in the <code>kdc.conf(4)</code> file.</p> <p><code>/etc/krb5/kadm5.acl</code></p> <p>kadmind uses an ACL (access control list) to determine which principals are allowed to perform Kerberos administration actions. The path of the ACL file is determined by the <code>acl_file</code> relation in the <code>kdc.conf</code> file. See <code>kdc.conf(4)</code>. For information regarding the format of the ACL file, refer to <code>kadm5.acl(4)</code>.</p> <p>After kadmind begins running, it puts itself in the background and disassociates itself from its controlling terminal.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><code>-d</code> Specifies that kadmind does not put itself in the background and does not disassociate itself from the terminal. In normal operation, you should use the default behavior, which is to allow the daemon to put itself in the background.</p> <p><code>-m</code> Specifies that the master database password should be retrieved from the keyboard rather than from the stash file. When using <code>-m</code>, the kadmind daemon receives the password prior to putting itself in the background. If used in combination with the <code>-d</code> option, you must explicitly place the daemon in the background.</p>

- p** *port-number* Specifies the port on which the `kadmin` daemon listens for connections. The default is controlled by the `kadmin_port` relation in the `kdc.conf(4)` file.
- r** *realm* Specifies the default realm that `kadmin` serves. If *realm* is not specified, the default *realm* of the host is used. `kadmin` answers requests for any realm that exists in the local KDC database and for which the appropriate principals are in its `keytab`.

**FILES**

- `/var/krb5/principal.db`  
Kerberos principal database.
- `/var/krb5/principal.kadm5`  
Kerberos administrative database containing policy information.
- `/var/krb5/principal.kadm5.lock`  
Kerberos administrative database lock file. This file works backwards from most other lock files (that is, `kadmin` exits with an error if this file does not exist).
- `/var/krb5/kadm5.dict`  
Dictionary of strings explicitly disallowed as passwords.
- `/etc/krb5/kadm5.acl`  
List of principals and their `kadmin` administrative privileges.
- `/etc/krb5/kadm5.keytab`  
Keytab for `kadmin/admin` principal.
- `/etc/krb5/kdc.conf`  
KDC configuration information.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkdca

**SEE ALSO**

`kpasswd(1)`, `gkadmin(1M)`, `kadmin(1M)`, `kadmin.local(1M)`, `kdb5_util(1M)`, `kadm5.acl(4)`, `kdc.conf(4)`, `attributes(5)`, `SEAM(5)`

## kdb5\_util(1M)

<b>NAME</b>	kdb5_util – Kerberos Database maintenance utility
<b>SYNOPSIS</b>	<code>/usr/sbin/kdb5_util [-d <i>dbname</i>] [-f <i>stashfile_name</i>] [-k <i>mkeytype</i>] [-m ]</code> <code>[-M <i>mkeyname</i>] [-P <i>password</i>] [-r <i>realm</i>] <i>cmd</i></code>
<b>DESCRIPTION</b>	kdb5_util enables you to create, dump, load, and destroy the Kerberos V5 database. You can also use kdb5_util to create a stash file containing the Kerberos database master key.
<b>OPTIONS</b>	The following options are supported:  -d <i>dbname</i> Specify the database name. .db is appended to whatever name is specified. You can specify an absolute path. If you do not specify the -d option, the default database name is /var/krb5/principal, which becomes /var/krb5/principal.db.  -f <i>stashfile_name</i> Specify the stash file name. You can specify an absolute path.  -k <i>mkeytype</i> Specify the master key type. Valid values are des-cbc-crc, des-cbc-md5, and des-cbc-raw.  -m Enter the master key manually.  -M <i>mkeyname</i> Specify the master key name.  -P <i>password</i> Use the specified <i>password</i> instead of the stash file.  -r <i>realm</i> Use <i>realm</i> as the default database realm.
<b>OPERANDS</b>	The following operands are supported:  <i>cmd</i> Specifies whether to create, destroy, dump, or load the database, or to create a stash file.  You can specify the following commands:  create -s Creates the database specified by the -d option. You will be prompted for the database master password. If you specify -s, a stash file is created as specified by the -f option. If you did not specify -f, the default stash file name is /var/krb5/.k5.realm. If you use the -f, -k, or -M options when you create a database, then you must use the same options when modifying or destroying the database.  destroy Destroys the database specified by the -d option.

**stash**

Creates a stash file. If `-f` was not specified, the default stash file name is `/var/krb5/.k5.realm`. You will be prompted for the master database password. This command is useful when you want to generate the stash file from the password.

**dump [-verbose] [filename] [principals]**

Dumps the Kerberos database to a flat file that can be used for loading or propagating to a slave KDC. See `kprop(1M)`. Specify file name for a location to dump the Kerberos database. If `filename` is not specified, the principal data is printed to standard error. Specify `-verbose` to print out the principal names to standard error in addition to being dumping into the file. Use `principals` to specify the list of principals that should be dumped.

**load [-verbose] [ -update ] filename**

Loads the database specified by `dbname` (see `-d` option, above) with data from the file specified by `filename`, which must be a file created by the `dump` command. Use `-update` to specify that the existing database should be updated; otherwise, a new database is created. Specify `-verbose` to print out the principal names to standard error, in addition to being loaded.

**EXAMPLES** **EXAMPLE 1** Creating File that Contains Information about Two Principals

The following example creates a file named `slavedata` that contains the information about two principals, `jdb@ACME.COM` and `pak@ACME.COM`.

```
/usr/krb5/bin/kdb5_util dump -verbose slavedata
jdb@ACME.COM pak@ACME.COM
```

**FILES**

`/var/krb5/principal.db`  
Kerberos principal database.

`/var/krb5/principal.kadm5`  
Kerberos administrative database. Contains policy information.

`/var/krb5/principal.kadm5.lock`  
Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, `kadmin` exits with an error if this file does not exist).

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkdcu

**SEE ALSO**

`kpasswd(1)`, `gkadmin(1M)`, `kadmin(1M)`, `kadmind(1M)`, `kadmin.local(1M)`, `kadm5.acl(4)`, `kdc.conf(4)`, `attributes(5)`, `SEAM(5)`

## kdmconfig(1M)

<b>NAME</b>	kdmconfig – configure or unconfigure keyboard, display, and mouse options for OpenWindows and internationalization
<b>SYNOPSIS</b>	<b>kdmconfig</b> <b>kdmconfig</b> [-fv] [-s <i>hostname</i> ] -c   -t   -u   -d <i>filename</i>
<b>DESCRIPTION</b>	<p>The <b>kdmconfig</b> program configures or unconfigures the <code>/etc/openwin/server/etc/OWconfig</code> file with the keyboard, display, and mouse information relevant to a client's machine on IA based systems for Solaris software. <b>kdmconfig</b> can also be used to set up the <i>display</i>, <i>pointer</i>, and <i>keyboard</i> entries in the <code>bootparams(4)</code> database on a server machine or the <i>monitor</i>, <i>keyboard</i>, <i>display</i>, and <i>pointer</i> keywords in a <code>sysidcfg(4)</code> file. <b>kdmconfig</b> can only be run by the super-user. Upon completion of device selection, <b>kdmconfig</b> prompts the user to test the configuration, which is done by running the window system.</p> <p>The <b>kdmconfig</b> program is normally run during installation and upon reboot, but it can also be run from the command line after the system has been installed. When configuring a client during an initial installation or a reconfigure reboot, the <code>sysidconfig(1M)</code> program will invoke <b>kdmconfig</b> with the <code>-c</code> option, and when the user executes the <code>sys-unconfig(1M)</code> program, <b>kdmconfig</b> will be executed with the <code>-u</code> option. Similarly, when you run <b>kdmconfig</b> from the command line, use the <code>-u</code> option to unconfigure the existing OpenWindows configuration. You can then rerun <b>kdmconfig</b> with the <code>-cf</code> options to create a new OpenWindows configuration. To edit the existing configuration, run <b>kdmconfig</b> from the command line without options. After each reboot, <b>kdmconfig</b> will be invoked by the system with the <code>-t</code> (test mode) option to ensure autoconfiguration capability and identify possible conflicts between the current configuration and the one recorded in the <code>OWconfig</code> file.</p>
<b>OPTIONS</b>	<p>The valid options are:</p> <p><code>-c</code> Run the program in the configuration mode. This mode is used to create or update the <code>OWconfig</code> file. When invoked in this way, <b>kdmconfig</b> first looks for the relevant configuration information in the <code>bootparams(4)</code> databases. It also takes into account the information returned from device probes, unless the <code>-s</code> option is also used. The <code>bootparams(4)</code> databases available to the client are all of the <code>/etc/bootparams</code> files on servers on the same subnet as the client, provided the server machine is running the <code>bootparamd(1M)</code> daemon. <b>kdmconfig</b> is invoked with the <code>-c</code> option when called by <code>sysidconfig(1M)</code></p> <p><code>-d filename</code> Set up a <code>sysidcfg(4)</code> file. This option displays the same screens as the <code>-c</code> option, but the information you specify is saved as <code>sysidcfg(4)</code> keywords (<i>monitor</i>, <i>keyboard</i>, <i>display</i>, and <i>pointer</i>). This enables you to use a <code>sysidcfg(4)</code> file to preconfigure a system's device information and bypass <b>kdmconfig</b> during an installation.</p>

	<i>filename</i> is the <code>sysidcfg(4)</code> file that is created, and it is created in the directory where <code>kdmconfig</code> is being run unless a path is specified. If <i>filename</i> already exists in the specified directory, the keywords are appended to the existing file.
<code>-f</code>	Force screens mode. When this option is invoked, no network probing will be performed. This is helpful when debugging the client's configuration environment. Note that the <code>-s</code> option implies the use of <code>-f</code> , bypassing network probing when setting up a server.
<code>-s hostname</code>	Set up the <code>bootparams(4)</code> database on this machine for the specified client. This option presents the same screens as it does when run on a client, but instead writes the resulting information to the <code>/etc/bootparams</code> file. Also, <code>-s</code> implies the use of the <code>-f</code> option. That is, the program will always present the screens to the user when invoked this way. This option will reconfigure the <code>nsswitch.conf(4)</code> file to look for a <code>bootparams(4)</code> database on a local server. This option is only available to the super-user.
<code>-t</code>	Run the program in test mode. In this mode, <code>kdmconfig</code> will use device probe information to determine whether the <code>OWconfig</code> file contains complete and up-to-date information about the keyboard, display, and mouse. If the information is accurate, <code>kdmconfig</code> will exit silently. Otherwise, <code>kdmconfig</code> will prompt for the super-user password and proceed to a normal editing session (as though it had been run without options).
<code>-u</code>	Unconfigure the system, returning it to an "out-of-the-box" state. In this state, the factory default keyboard, mouse, and display are selected as a result of removing the device configuration entries from the <code>/etc/openwin/server/etc/OWconfig</code> file. This may result in an unusable configuration for the display server.
<code>-v</code>	Enable verbose mode. Normally, <code>kdmconfig</code> will not produce any output. This option is helpful for debugging, as it records the different actions taken by <code>kdmconfig</code> on <code>stderr</code> .
<b>No Options</b>	Run without options, <code>kdmconfig</code> is used to edit the current configuration. <code>kdmconfig</code> uses the information from the <code>OWconfig</code> file in addition to information obtained from the <code>bootparams(4)</code> file and from device probes. In other respects, it is similar to using the <code>-c</code> option of <code>kdmconfig</code> .
<b>FILES</b>	<p><code>/etc/openwin/server/etc/OWconfig</code> OpenWindows configuration file</p> <p><code>/etc/bootparams</code> contains list of clients that diskless clients use for booting</p> <p><code>/etc/nsswitch.conf</code> name service configuration file</p>

kdmconfig(1M)

**IA Only** /dev/openprom installed devices and properties

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	IA
Availability	SUNWos86r

**SEE ALSO** `bootparamd(1M)`, `sys-unconfig(1M)`, `sysidconfig(1M)`, `bootparams(4)`, `nsswitch.conf(4)`, `sysidcfg(4)`, `attributes(5)`

<b>NAME</b>	kernel – UNIX system executable file containing basic operating system services
<b>SYNOPSIS</b>	<b>kernel-name</b> [-afsrvx]
<b>DESCRIPTION</b>	<p>The operating system image, or kernel, is the collection of software comprising the image files (<code>unix</code> and <code>genunix</code>) and the modules loaded at any instant in time. The system will not function without a kernel to control it.</p> <p>The kernel is loaded by the <code>boot(1M)</code> command in a machine-specific way. The kernel may be loaded from disk or CD-ROM (<code>diskfull boot</code>) or over the network (<code>diskless boot</code>). In either case, the directories under <code>/platform</code> and <code>/kernel</code> must be readable and must contain executable code which is able to perform the required kernel service. If the <code>-a</code> flag is given, the user is able to supply different pathnames for the default locations of the kernel and modules. See <code>boot(1M)</code> for more information on loading a specific kernel.</p> <p>If the kernel name is not explicitly specified, then on systems capable of supporting the 64-bit kernel, the boot program will attempt to load the 64-bit kernel in preference to the 32-bit kernel by default. See <code>boot(1m)</code>.</p> <p>The <code>moddir</code> variable contains a colon-separated list of directories that the kernel searches for modules. <code>moddir</code> can be set in the <code>/etc/system</code> file. The minimal default is <code>/platform/platform-name/kernel:/kernel:/usr/kernel</code>, but this default they be overridden by a specific platform. It is common for many systems to override the default path with</p> <pre style="margin-left: 2em;">/platform/platform-name/kernel:/platform/hardware-class-name\ /kernel:/kernel:/usr/kernel</pre> <p>where <i>platform-name</i> can be found using the <code>-i</code> option of <code>uname(1)</code>, and <i>hardware-class-name</i> can be found using the <code>-m</code> option of <code>uname(1)</code>.</p> <p>The kernel configuration can be controlled using the <code>/etc/system</code> file (see <code>system(4)</code>).</p> <p><code>genunix</code> is the platform-independent component of the base kernel.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a       Asks the user for configuration information, such as where to find the system file, where to mount <code>root</code>, and even override the name of the kernel itself. Default responses will be contained in square brackets ([ ]), and the user may simply enter RETURN to use the default response (note that RETURN is labeled ENTER on some keyboards). To help repair a damaged <code>/etc/system</code> file, enter <code>/dev/null</code> at the prompt that asks for the pathname of the system configuration file. See <code>system(4)</code>.</li> <li>-f       Causes Autoclient systems to flush and reinitialize the client system's local cache. This flag is ignored for all non-Autoclient systems.</li> <li>-r       Reconfiguration boot. The system will probe all attached hardware devices and assign nodes in the file system to represent only those devices actually</li> </ul>

## kernel(1M)

found. It will also configure the logical namespace in `/dev` as well as the physical namespace in `/devices`. See `add_drv(1M)` and `rem_drv(1M)` for additional information about maintaining device drivers.

- s Boots only to init level 's'. See `init(1M)`.
- v Boots with verbose messages enabled. If this flag is not given, the messages are still printed, but the output is directed to the system logfile. See `syslogd(1M)`.
- x Does not boot in clustered mode. This option only has an effect when a version of Sun Cluster software that supports this option has been installed.

**EXAMPLES** See `boot(1M)` for examples and instructions on how to boot.

### FILES

`/kernel`

Contains kernel components common to all platforms within a particular instruction set that are needed for booting the system. of the core image file.

`/platform/platform-name/kernel`

The platform-specific kernel components.

`/platform/hardware-class-name/kernel`

The kernel components specific to this hardware class.

`/usr/kernel`

Contains kernel components common to all platforms within a particular instruction set.

The directories in this section can potentially contain the following subdirectories:

- `drv` Loadable device drivers
- `exec` The modules that execute programs stored in various file formats.
- `fs` File system modules
- `misc` Miscellaneous system-related modules
- `sched` Operating system schedulers
- `strmod` System V STREAMS loadable modules
- `sys` Loadable system calls

### SPARC

Additionally, the subdirectories mentioned in this section may contain `sparcv9` subdirectories that contain 64-bit versions of the same module classes.

`cpu` Processor specific modules

`tod` Time-Of-Day hardware interface modules

### IA

`mach` IA hardware support

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcar, SUNWcarx

**SEE ALSO** `uname(1)`, `isainfo(1)`, `add_drv(1M)`, `boot(1M)`, `init(1M)`, `kadb(1M)`, `rem_drv(1M)`, `savecore(1M)`, `syslogd(1M)`, `system(4)`, `attributes(5)`

**SPARC Only** `monitor(1M)`

**DIAGNOSTICS** The kernel gives various warnings and error messages. If the kernel detects an unrecoverable fault, it will panic or halt.

**BUGS** Bugs in the kernel often result in kernel panics.

Reconfiguration boot does not currently remove filesystem entries for devices that have been physically removed from the system.

keyserv(1M)

**NAME** keyserv – server for storing private encryption keys

**SYNOPSIS** **keyserv** [-c] [-d] [-D] [-n] [-s *sizespec*]

**DESCRIPTION** *keyserv* is a daemon that is used for storing the private encryption keys of each user logged into the system. These encryption keys are used for accessing secure network services such as secure NFS and NIS+.

Normally, root’s key is read from the file */etc/.rootkey* when the daemon is started. This is useful during power-fail reboots when no one is around to type a password.

**OPTIONS**

- c Do not use disk caches. This option overrides any -s option.
- d Disable the use of default keys for nobody.
- D Run in debugging mode and log all requests to *keyserv*.
- n Root’s secret key is not read from */etc/.rootkey*. Instead, *keyserv* prompts the user for the password to decrypt root’s key stored in the *publickey* database and then stores the decrypted key in */etc/.rootkey* for future use. This option is useful if the */etc/.rootkey* file ever gets out of date or corrupted.
- s *sizespec* Specify the size of the extended Diffie-Hellman common key disk caches. The *sizespec* can be one of the following forms:
  - mechtype=size* *size* is an integer specifying the maximum number of entries in the cache, or an integer immediately followed by the letter *M*, denoting the maximum size in MB.
  - size* This form of *sizespec* applies to all caches.
 See *nisauthconf(1M)* for mechanism types. Note that the *des* mechanism, *AUTH\_DES*, does not use a disk cache.

**FILES** */etc/.rootkey*

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** *keylogin(1)*, *keylogout(1)*, *nisauthconf(1M)*, *publickey(4)*, *attributes(5)*

**NOTES** *keyserv* will not start up if the system does not have a secure *rpc* domain configured. Set up the domain name by using the */usr/bin/domainname* command. Usually the */etc/init.d/inetinit* script reads the domain from

keyserv(1M)

/etc/defaultdomain. Invoking the domainname command without arguments tells you if you have a domain set up.

killall(1M)

**NAME** | killall – kill all active processes

**SYNOPSIS** | `/usr/sbin/killall [signal]`

**DESCRIPTION** | killall is used by shutdown(1M) to kill all active processes not directly related to the shutdown procedure.

| killall terminates all processes with open files so that the mounted file systems will be unbusied and can be unmounted.

| killall sends *signal* (see kill(1)) to the active processes. If no *signal* is specified, a default of 15 is used.

| The killall command can be run only by the super-user.

**ATTRIBUTES** | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** | kill(1), ps(1), fuser(1M), shutdown(1M), signal(3C), attributes(5)

<b>NAME</b>	kprop – Kerberos database propagation program
<b>SYNOPSIS</b>	<code>/usr/lib/kprop [-d] [-f <i>file</i>] [-p <i>port-number</i>] [-r <i>realm</i>] [-s <i>keytab</i>] [<i>host</i>]</code>
<b>DESCRIPTION</b>	<p>kprop is a command-line utility used for propagating a Kerberos database from a master KDC to a slave KDC. This command must be run on the master KDC. See the <i>Solaris System Administration Guide, Vol. 6</i> on how to set up periodic propagation between the master KDC and slave KDCs.</p> <p>To propagate a Kerberos database, the following conditions must be met:</p> <ul style="list-style-type: none"> <li>■ The slave KDCs must have an <code>/etc/krb5/kpropd.ac1</code> file that contains the principals for the master KDC and all the slave KDCs.</li> <li>■ A keytab containing a host principal entry must exist on each slave KDC.</li> <li>■ The database to be propagated must be dumped to a file using <code>kdb5_util(1M)</code>.</li> </ul>
<b>OPTIONS</b>	<p><code>-d</code> Enable debug mode. Default is debug mode disabled.</p> <p><code>-f <i>file</i></code> File to be sent to the slave KDC. Default is the <code>/var/krb5/slave_datatrans</code> file.</p> <p><code>-p <i>port-number</i></code> Propagate <i>port-number</i>. Default is port 754.</p> <p><code>-r <i>realm</i></code> Realm where propagation will occur. Default <i>realm</i> is the local realm.</p> <p><code>-s <i>keytab</i></code> Location of the keytab. Default location is <code>/etc/krb5/krb5.keytab</code>.</p>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>host</i> Name of the slave KDC.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Propagating the Kerberos Database</p> <p>The following example propagates the Kerberos database from the <code>/tmp/slave_data</code> file to the slave KDC <code>london</code>. The machine <code>london</code> must have a host principal keytab entry and the <code>kpropd.ac1</code> file must contain an entry for the all the KDCs.</p> <pre># kprop -f /tmp/slave_data london</pre>
<b>FILES</b>	<p><code>/etc/krb5/kpropd.ac1</code> List of principals of all the KDCs; resides on each slave KDC.</p> <p><code>/etc/krb5/krb5.keytab</code> Keytab for Kerberos clients.</p> <p><code>/var/krb5/slave_datatrans</code> Kerberos database propagated to the KDC slaves.</p>

kprop(1M)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkdcu

**SEE ALSO** `kpasswd(1)`, `gkadmin(1M)`, `kadmind(1M)`, `kadmin.local(1M)`, `kdb5_util(1M)`, `kadm5.acl(4)`, `kdc.conf(4)`, `attributes(5)`, `SEAM(5)`

*Solaris System Administration Guide, Security Services*

<b>NAME</b>	krb5kdc – KDC daemon
<b>SYNOPSIS</b>	<code>/usr/lib/krb5kdc [-d <i>dbpath</i>] [-r <i>realm</i>] [-R <i>replaycachename</i>] [-m] [-k <i>masterenctype</i>] [-M <i>masterkeyname</i>] [-p <i>port</i>] [-n]</code>
<b>DESCRIPTION</b>	krb5kdc is the daemon that runs on the master and slave KDCs to process the Kerberos tickets. For Kerberos to function properly, krb5kdc must be running on at least one KDC that the Kerberos clients can access. Prior to running krb5kdc, you must initialize the Kerberos database using kdb5_util(1M). See the <i>Solaris System Administration Guide, Security Services</i> or instructions on setting up KDCs and initialize the Kerberos database.
<b>OPTIONS</b>	The following options are supported: <ul style="list-style-type: none"> <li>-d <i>dbpath</i> Specify the path to the database; default value is /var/krb5.</li> <li>-r <i>realm</i> Specify the realm name; default is the local realm name.</li> <li>-R <i>replaycachename</i> Specify the replay cache name; default value is krb5kdc_rcache.</li> <li>-m Specify that the master key for the database is to be entered manually.</li> <li>-k <i>masterenctype</i> Specify the encryption type for encrypting the database. The default value is des-cbc-crc.</li> <li>-M <i>masterkeyname</i> Specify the principal to retrieve the master key for the database.</li> <li>-p <i>port</i> Specify the port that will be used by the KDC to listen for incoming requests.</li> <li>-n Specify that krb5kdc should not detach from the terminal.</li> </ul>
<b>FILES</b>	<ul style="list-style-type: none"> <li>/var/krb5/principal.db Kerberos principal database.</li> <li>/var/krb5/principal.kadm5 Kerberos administrative database. This file contains policy information.</li> <li>/var/krb5/principal.kadm5.lock Kerberos administrative database lock file. This file works backwards from most other lock files (that is, kadmin will exit with an error if this file does <i>not</i> exist).</li> <li>/etc/krb5/kdc.conf KDC configuration file. This file is read at startup.</li> <li>/etc/krb5/kpropd.acl File that defines the access control list for propagating the Kerberos database using kprop.</li> </ul>

krb5kdc(1M)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkdcu

*Solaris System Administration Guide, Security Services*

<b>NAME</b>	kstat – display kernel statistics														
<b>SYNOPSIS</b>	<pre><b>kstat</b> [-lpq] [-T u   d] [-c <i>class</i>] [-m <i>module</i>] [-i <i>instance</i>] [-n <i>name</i>]         [-s <i>statistic</i>] [interval [count]]  <b>kstat</b> [-lpq] [-T u   d] [-c <i>class</i>] [<i>module:instance:name:statistic...</i>]         [interval [count]]</pre>														
<b>DESCRIPTION</b>	<p>The <code>kstat</code> utility examines the available kernel statistics, or kstats, on the system and reports those statistics which match the criteria specified on the command line. Each matching statistic is printed with its module, instance, and name fields, as well as its actual value.</p> <p>Kernel statistics may be published by various kernel subsystems, such as drivers or loadable modules; each kstat has a module field that denotes its publisher. Since each module may have countable entities (such as multiple disks associated with the <code>sd(7D)</code> driver) for which it wishes to report statistics, the <code>kstat</code> also has an instance field to index the statistics for each entity; <code>kstat</code> instances are numbered starting from zero. Finally, the kstat is given a name unique within its module.</p> <p>Each kstat may be a special kstat type, an array of name-value pairs, or raw data. In the name-value case, each reported value is given a label, which we refer to as the statistic. Known raw and special kstats are given statistic labels for each of their values by <code>kstat</code>; thus, all published values can be referenced as <code>module:instance:name:statistic</code>.</p> <p>When invoked without any module operands or options, <code>kstat</code> will match all defined statistics on the system. Example invocations are provided below. All times are displayed as fractional seconds since system boot.</p>														
<b>OPTIONS</b>	<p>The tests specified by the following options are logically ANDed, and all matching kstats will be selected. A regular expression containing shell meta-characters must be protected from the shell by enclosing it with the appropriate quotes.</p> <p>The argument for the <code>-c</code>, <code>-i</code>, <code>-m</code>, <code>-n</code>, and <code>-s</code> options may be specified as a shell glob pattern, or a Perl regular expression enclosed in <code>'/'</code> characters.</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>-c <i>class</i></code></td> <td>Displays only kstats that match the specified class.</td> </tr> <tr> <td><code>-i <i>instance</i></code></td> <td>Displays only kstats that match the specified instance.</td> </tr> <tr> <td><code>-l</code></td> <td>Lists matching kstat names without displaying values.</td> </tr> <tr> <td><code>-m <i>module</i></code></td> <td>Displays only kstats that match the specified module.</td> </tr> <tr> <td><code>-n <i>name</i></code></td> <td>Displays only kstats that match the specified name.</td> </tr> <tr> <td><code>-p</code></td> <td>Displays output in parseable format. All example output in this document is given in this format. If this option is not specified, <code>kstat</code> produces output in a human-readable, table format.</td> </tr> <tr> <td><code>-q</code></td> <td>Displays no output, but return appropriate exit status for matches against given criteria.</td> </tr> </table>	<code>-c <i>class</i></code>	Displays only kstats that match the specified class.	<code>-i <i>instance</i></code>	Displays only kstats that match the specified instance.	<code>-l</code>	Lists matching kstat names without displaying values.	<code>-m <i>module</i></code>	Displays only kstats that match the specified module.	<code>-n <i>name</i></code>	Displays only kstats that match the specified name.	<code>-p</code>	Displays output in parseable format. All example output in this document is given in this format. If this option is not specified, <code>kstat</code> produces output in a human-readable, table format.	<code>-q</code>	Displays no output, but return appropriate exit status for matches against given criteria.
<code>-c <i>class</i></code>	Displays only kstats that match the specified class.														
<code>-i <i>instance</i></code>	Displays only kstats that match the specified instance.														
<code>-l</code>	Lists matching kstat names without displaying values.														
<code>-m <i>module</i></code>	Displays only kstats that match the specified module.														
<code>-n <i>name</i></code>	Displays only kstats that match the specified name.														
<code>-p</code>	Displays output in parseable format. All example output in this document is given in this format. If this option is not specified, <code>kstat</code> produces output in a human-readable, table format.														
<code>-q</code>	Displays no output, but return appropriate exit status for matches against given criteria.														

## kstat(1M)

`-s statistic` Displays only kstats that match the specified statistic.

`-T d | u` Displays a time stamp before each statistics block, either in `ctime(3C)` format ('d') or as an alphanumeric representation of the value returned by `time(2)` ('u').

**OPERANDS** The following operands are supported:

*module:instance:name:statistic* Alternate method of specifying module, instance, name, and statistic as described above. Each of the module, instance, name, or statistic specifiers may be a shell glob pattern or a Perl regular expression enclosed by '/' characters. It is possible to use both specifier types within a single operand. Leaving a specifier empty is equivalent to using the '\*' glob pattern for that specifier.

*interval* The number of seconds between reports.

*count* The number of reports to be printed.

**EXAMPLES** In the following examples, all the command lines in a block produce the same output, as shown immediately below. The exact statistics and values will of course vary from machine to machine.

### EXAMPLE 1

```
example$ kstat -p -m unix -i 0 -n system_misc -s 'avenrun*'
example$ kstat -p -s 'avenrun*'
example$ kstat -p 'unix:0:system_misc:avenrun*'
example$ kstat -p ' :::avenrun*'
example$ kstat -p ' :::/^avenrun_/d+min$/'
```

```
unix:0:system_misc:avenrun_15min 3
unix:0:system_misc:avenrun_1min 4
unix:0:system_misc:avenrun_5min 2
```

### EXAMPLE 2

```
example$ kstat -p -m cpu_stat -s 'intr*'
example$ kstat -p cpu_stat:::/^intr/
```

```
cpu_stat:0:cpu_stat0:intr 29682330
cpu_stat:0:cpu_stat0:intrblk 87
cpu_stat:0:cpu_stat0:intrthread 15054222
cpu_stat:1:cpu_stat1:intr 426073
cpu_stat:1:cpu_stat1:intrblk 51
cpu_stat:1:cpu_stat1:intrthread 289668
cpu_stat:2:cpu_stat2:intr 134160
cpu_stat:2:cpu_stat2:intrblk 0
cpu_stat:2:cpu_stat2:intrthread 131
cpu_stat:3:cpu_stat3:intr 196566
```

**EXAMPLE 2** (Continued)

```
cpu_stat:3:cpu_stat3:intrblk 30
cpu_stat:3:cpu_stat3:intrthread 59626
```

**EXAMPLE 3**

```
example$ kstat -p :::state '::::avenrun*'
example$ kstat -p :::state :::/^avenrun/
```

```
cpu_info:0:cpu_info0:state on-line
cpu_info:1:cpu_info1:state on-line
cpu_info:2:cpu_info2:state on-line
cpu_info:3:cpu_info3:state on-line
unix:0:system_misc:avenrun_15min 4
unix:0:system_misc:avenrun_1min 10
unix:0:system_misc:avenrun_5min 3
```

**EXAMPLE 4**

```
example$ kstat -p 'unix:0:system_misc:avenrun*' 1 3
unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21
```

```
unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21
```

```
unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21
```

**EXAMPLE 5**

```
example$ kstat -p -T d 'unix:0:system_misc:avenrun*' 5 2
Thu Jul 22 19:39:50 1999
unix:0:system_misc:avenrun_15min 12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11
```

```
Thu Jul 22 19:39:55 1999
unix:0:system_misc:avenrun_15min 12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11
```

**EXAMPLE 6**

```
example$ kstat -p -T u 'unix:0:system_misc:avenrun*'
932668656
unix:0:system_misc:avenrun_15min 14
unix:0:system_misc:avenrun_1min 5
unix:0:system_misc:avenrun_5min 18
```

kstat(1M)

**EXAMPLE 6**    *(Continued)*

**EXIT STATUS**

The following exit values are returned:

- 0            One or more statistics were matched.
- 1            No statistics were matched.
- 2            Invalid command line options were specified.
- 3            A fatal error occurred.

**FILES**

/dev/kstat    kernel statistics driver

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO**

`sh(1)`, `time(2)`, `ctime(3C)`, `gmatch(3GEN)`, `kstat(3KSTAT)`, `attributes(5)`, `kstat(7D)`, `sd(7D)`, `kstat(9S)`

**NOTES**

If the pattern argument contains glob or Perl RE meta-characters which are also shell meta-characters, it will be necessary to enclose the pattern with appropriate shell quotes.

**NAME** kttkt\_warnd – Kerberos warning daemon

**SYNOPSIS** /usr/lib/krb5/kttkt\_warnd

**DESCRIPTION** kttkt\_warnd is a daemon on Kerberos clients that can warn users when their Kerberos tickets are about to expire. It is invoked by inetd when a ticket-granting ticket (TGT) is obtained for the first time, such as after using the kinit command. kttkt\_warnd can be configured through the /etc/krb5/warn.conf file on the client.

**FILES** /etc/krb5/warn.conf                      Kerberos warning configuration file

**SEE ALSO** inetd(1M), warn.conf(4), SEAM(5)

## labelit(1M)

<b>NAME</b>	labelit – list or provide labels for file systems
<b>SYNOPSIS</b>	<b>labelit</b> [-F <i>FSType</i> ] [-V] [-o <i>FSType-specific-options</i> ] <i>special</i> [ <i>operands</i> ]
<b>DESCRIPTION</b>	The <code>labelit</code> utility is used to write or display labels on unmounted disk file systems.
<b>OPTIONS</b>	The following options are supported:  -F <i>FSType</i> Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <code>/etc/vfstab</code> by matching the <i>special</i> with an entry in the table. If no matching entry is found, the default file system type specified in <code>/etc/default/fs</code> will be used.  -V                    Echo complete command line. This option may be used to verify and validate the command line. Additional information obtained using a <code>/etc/vfstab</code> lookup is included in the output. The command is not executed.  -o                    Specify <i>FSType</i> -specific options. See the manual page for the <code>labelit</code> module specific to the file system type.
<b>OPERANDS</b>	The following operands are supported. If no operands are specified, <code>labelit</code> will display the value of the labels.  <i>special</i> The disk partition (for example, <code>/dev/rdisk/c0t3d0s6</code> ). The device may not be on a remote machine.  <i>operands</i> <i>FSType</i> -specific operands. Consult the manual page of the <i>FSType</i> -specific <code>labelit</code> command for detailed descriptions.
<b>USAGE</b>	See <code>largefile(5)</code> for the description of the behavior of <code>labelit</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).
<b>EXIT STATUS</b>	The following exit values are returned:  0                    Write or display of labels was successful.  non-zero            An error occurred.
<b>FILES</b>	<code>/etc/vfstab</code> List of default parameters for each file system.  <code>/etc/default/fs</code> Default local file system type. Default values can be set for the following flags in <code>/etc/default/fs</code> . For example:  LOCAL= <i>ufs</i> LOCAL                The default partition for a command if no <i>FSType</i> is specified.
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

labelit(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** labelit\_hfs(1M), labelit\_udfs(1M), labelit\_ufs(1M), volcopy(1M), vfstab(4), attributes(5), largefile(5)

**NOTES** This utility may not be supported for all *FSTypes*.

labelit\_hfs(1M)

**NAME** labelit\_hfs – provide and print labels for hfs file systems

**SYNOPSIS** /usr/sbin/labelit -F hfs [generic\_options] [-o specific\_options] special

**DESCRIPTION** labelit can be used to provide labels for unmounted CD-ROM images (CD-ROMs may not be labeled, as they are read-only media).

generic\_options are options supported by the generic labelit command.

If no specific\_options are specified, labelit prints the current value of all label fields.

The special name should be the physical disk section (for example, /dev/dsk/c0d0s6).

**OPTIONS**

- o Use one or more of the following name=value pairs separated by commas (with no intervening spaces) to specify values for specific label fields. According to the ISO 9660 specification, only certain sets of characters may be used to fill in these labels. Thus, "d-characters" below refers to the characters 'A' through 'Z', the digits '0' through '9', and the '\_' (underscore) character. "a-characters" below refers to 'A' through 'Z', '0' through '9', space, and the following characters: !"%&'()\*+,-./:;<=>?\_.

absfile=	Abstract file identifier, d-characters, 37 characters maximum.
applid=	Application identifier, d-characters, 128 characters maximum.
bibfile=	Bibliographic file identifier, d-characters, 37 characters maximum.
copyfile=	Copyright file identifier, d-characters, 128 maximum.
prepid=	Data preparer identifier, d-characters, 128 maximum.
pubid=	Publisher identifier, d-characters, 128 maximum.
sysid=	System identifier, a-characters, 32 maximum.
volid=	Volume identifier, d-characters, 32 maximum.
volsetid=	Volume set identifier, d-characters, 128 maximum.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** labelit(1M), volcopy(1M), attributes(5)

<b>NAME</b>	labelit_udfs – provide and print labels for udf file systems
<b>SYNOPSIS</b>	<b>labelit</b> -F udfs [ <i>generic_options</i> ] [-o <i>specific_options</i> ] <i>special</i> [ <i>fsname volume</i> ]
<b>DESCRIPTION</b>	The <b>labelit</b> command writes labels on an unmounted disk that contains a universal disk file (udf) system. These labels can be used to identify volumes.
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><i>generic_options</i> Specify <i>generic_options</i> supported by the generic <b>labelit</b> command. See <b>labelit(1M)</b> for descriptions of supported options.</p> <p>-o <i>specific_options</i> Specify udfs-file-system-specific options in a comma-separated list with no intervening spaces. The following <i>specific_options</i> are available:</p> <p><i>lvinfo1=string</i> Specify information to be inserted in the LVInfo1 field of the Implementation Use Volume Descriptor. Information in LVInfo1 is generally used to identify the person creating the file system. The maximum length of the string specified is 35 bytes.</p> <p><i>lvinfo2=string</i> Specify information to be inserted into the LVInfo2 field of the Implementation Use Volume Descriptor. Information in LVInfo2 is generally used to identify the organization responsible for creating the file system. The maximum length of the string specified is 35 bytes.</p> <p><i>lvinfo3=string</i> Specify information to be inserted into the LVInfo3 field of the Implementation Use Volume Descriptor. Information in LVInfo3 is generally used to identify the contact information for the medium. The maximum length of the string specified is 35 bytes.</p>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>special</i> Specify <i>special</i> as the physical disk slice, for example, /dev/rdisk/c0t0d0s6. The device can not be on a remote machine.</p> <p><i>fsname</i> Specify <i>fsname</i> as the mount point, (for example, root, u1, and so forth), of the file system.</p> <p><i>volume</i> Specify <i>volume</i> as the physical volume name.</p> <p>If none of the options (<i>fsname</i>, <i>volume</i>, <i>specific_options</i>) is specified, <b>labelit</b> prints the current values of <i>fsname</i>, <i>volume</i>, LVInfo1, LVInfo2 and LVInfo3.</p>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0 Successful completion.</p>

labelit\_udfs(1M)

non-zero            An error occurred.

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

<b>NAME</b>	labelit_ufs – provide and print labels for ufs file systems				
<b>SYNOPSIS</b>	<b>labelit</b> -F ufs [ <i>generic_options</i> ] <i>special</i> [ <i>fsname volume</i> ]				
<b>DESCRIPTION</b>	labelit is used to write labels on unmounted disk file systems. Such labels may be used to uniquely identify volumes and are used by volume-oriented programs such as volcopy(1M).				
<b>OPTIONS</b>	The following option is supported:  <i>generic_options</i> options supported by the generic labelit command. See labelit(1M).				
<b>OPERANDS</b>	The following operands are supported:  <i>special</i> name should be the physical disk section (for example, /dev/dsk/c0d0s6). The device may not be on a remote machine.  <i>fsname</i> represents the mount point (for example, root, u1, and so on) of the file system.  <i>volume</i> may be used to represent the physical volume name.  If <i>fsname</i> and <i>volume</i> are not specified, labelit prints the current values of these labels. Both <i>fsname</i> and <i>volume</i> are limited to six or fewer characters.				
<b>EXIT STATUS</b>	The following exit values are returned:  0                      Write or display of labels was successful.  non-zero              An error occurred.				
<b>ATTRIBUTES</b>	See attributes(5) for descriptions of the following attributes:

## ldapaddent(1M)

<b>NAME</b>	ldapaddent – create LDAP entries from corresponding /etc files
<b>SYNOPSIS</b>	<b>ldapaddent</b> [-cpv] [-a <i>authenticationMethod</i> ] [-b <i>baseDN</i> ] -D <i>bindDN</i> -w <i>bind_password</i> [-f <i>filename</i> ] <i>database</i> <b>ldapaddent</b> -d [-v] [-a <i>authenticationMethod</i> ] [-b <i>baseDN</i> ] [-D <i>bindDN</i> ] [-w <i>bind_password</i> ] <i>database</i>
<b>DESCRIPTION</b>	<p>ldapaddent creates entries in LDAP containers from their corresponding /etc files. This operation is customized for each of the standard containers that are used in the administration of Solaris systems. The <i>database</i> argument specifies the type of the data being processed. Legal values for this type are one of <i>aliases</i>, <i>auto_*</i>, <i>bootparams</i>, <i>ethers</i>, <i>group</i>, <i>hosts</i> (including IPv6 addresses), <i>netgroup</i>, <i>netmasks</i>, <i>networks</i>, <i>passwd</i>, <i>shadow</i>, <i>protocols</i>, <i>publickey</i>, <i>rpc</i>, and <i>services</i>.</p> <p>By default, ldapaddent reads from the standard input and adds this data to the LDAP container associated with the database specified on the command line. An input file from which data can be read is specified using the -f option.</p> <p>The entries will be stored in the directory based on the client's configuration, thus the client must be configured to use LDAP naming services. The location where entries are to be written can be overridden by using the -b option.</p> <p>If an entry being added exists in the directory, the command displays an error and exits unless the -c option is used.</p> <p>Although, there is a shadow database type, there is no corresponding shadow container. Both the shadow and the passwd data is stored in the people container itself. Similarly, data from networks and netmasks databases are stored in the networks container.</p> <p>For better performance, the recommended order in which the databases should be loaded is as follows:</p> <ul style="list-style-type: none"><li>■ passwd database followed by shadow database</li><li>■ networks database followed by netmasks database</li><li>■ bootparams database followed by ethers database</li></ul>
<b>OPTIONS</b>	<p>The ldapaddent command supports the following options:</p> <p>-a <i>authenticationMethod</i> Specify authentication method. The default value is what has been configured in the profile. The supported authentication methods are:</p> <ul style="list-style-type: none"><li>simple</li><li>sasl/CRAM-MD5</li><li>sasl/DIGEST-MD5</li><li>tls:simple</li><li>tls:sasl/CRAM-MD5</li><li>tls:sasl/DIGEST-MD5</li></ul>

## ldapaddent(1M)

Selecting `simple` causes passwords to be sent over the network in clear text. Its use is strongly discouraged. Additionally, if the client is configured with a profile which uses no authentication, that is, either the `credentialLevel` attribute is set to `anonymous` or `authenticationMethod` is set to `none`, the user must use this option to provide an authentication method.

`-b baseDN`

Create entries in the *baseDN* directory. *baseDN* is not relative to the client's default search base, but rather, it is the actual location where the entries will be created. If this parameter is not specified, the first search descriptor defined for the service or the default container will be used.

`-c`

Continue adding entries to the directory even after an error. Entries will not be added if the directory server is not responding or if there is an authentication problem.

`-D bindDN`

Create an entry which has write permission to the *baseDN*. When used with `-d` option, this entry only needs read permission.

`-d`

Dump the LDAP container to the standard output in the appropriate format for the given database.

`-f filename`

Indicates input file to read in an */etc/* file format.

`-p`

Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid, as the actual password appears in a shadow file.

`-w bind_password`

Password to be used for authenticating the *bindDN*. If this parameter is missing, the command will prompt for a password. NULL passwords are not supported in LDAP.

`-v`

Verbose.

**OPERANDS** The following operands are supported:

*database*

The name of the database or service name. Supported values are: `aliases`, `auto_*`, `bootparams`, `ethers`, `group`, `hosts` (including IPv6 addresses), `netgroup`, `netmasks`, `networks`, `passwd`, `shadow`, `protocols`, `publickey`, `rpc`, and `services`.

**EXAMPLES** **EXAMPLE 1** Adding Password Entries to the Directory Server

The following example show how to add password entries to the directory server:

## ldapaddent(1M)

### EXAMPLE 1 Adding Password Entries to the Directory Server *(Continued)*

```
example# ldapaddent -D "cn=directory manager" -w secret \
-f /etc/passwd passwd
```

### EXAMPLE 2 Adding Group Entries

The following example shows how to add group entries to the directory server using sasl/CRAM-MD5 as the authentication method:

```
example# ldapaddent -D "cn=directory manager" -w secret \
-a "sasl/CRAM-MD5" -f /etc/group group
```

### EXAMPLE 3 Adding auto\_master Entries

The following example shows how to add auto\_master entries to the directory server:

```
example# ldapaddent -D "cn=directory manager" -w secret \
-f /etc/auto_master auto_master
```

### EXAMPLE 4 Dumping password Entries from the Directory to File

The following examples shows how to dump password entries from the directory to a file foo:

```
example# ldapaddent -d passwd > foo
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES** /var/ldap/ldap\_client\_file  
/var/ldap/ldap\_client\_cred

Files containing the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use ldapclient(1M) to update these files.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

idsconfig(1M), ldapclient(1M), suninstall(1M), attributes(5)

## ldap\_cachemgr(1M)

<b>NAME</b>	ldap_cachemgr – LDAP daemon to manage client configuration for LDAP based Network Information Service lookups
<b>SYNOPSIS</b>	<code>/usr/lib/ldap/ldap_cachemgr [-l <i>log-file</i>] [-g]</code>
<b>DESCRIPTION</b>	<p>The ldap_cachemgr daemon is a process that provides an up-to-date configuration cache for LDAP naming services. It is started during multi-user boot.</p> <p>The ldap_cachemgr utility provides caching for all parameters as specified and used by the LDAP naming service clients. The ldap_cachemgr utility uses the cache files which are originally created by executing the ldapclient(1M) utility, as cold start files. Updates to the cache files take place dynamically if profiles are used to configure the client. See the init option to ldapclient(1M).</p> <p>The ldap_cachemgr utility helps improve the performance of the clients that are using LDAP as the Naming service repository. In order for the LDAP naming services to function properly, the ldap_cachemgr daemon must be running. ldap_cachemgr also improves system security by making the configuration files readable by superuser only.</p> <p>The cache maintained by this daemon is shared by all the processes that access LDAP Naming information. All processes access this cache through a door call. On startup, ldap_cachemgr initializes the cache from the cache files. See ldapclient(1M). Thus, the cache survives machine reboots.</p> <p>The ldap_cachemgr daemon also acts as its own administration tool. If an instance of ldap_cachemgr is already running, commands are passed transparently to the running version.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p>-g                                   Print current configuration and statistics to standard output. This is the only option executable without superuser privileges.</p> <p>-l <i>log-file</i>                       Cause ldap_cachemgr to use a log file other than the default <code>/var/ldap/cachemgr.log</code>.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Stopping and Restarting the ldap_cachemgr Daemon</p> <p>The following example shows how to stop and to restart the ldap_cachemgr daemon.</p> <pre>example# /etc/init.d/ldap.client stop example# /etc/init.d/ldap.client start</pre> <p><b>EXAMPLE 2</b> Forcing ldap_cachemgr to Reread the <code>/var/ldap/ldap_client_file</code> and <code>/var/ldap/ldap_client_cred</code> Files</p> <p>The following example shows how to force ldap_cachemgr to reread the <code>/var/ldap/ldap_client_file</code> and <code>/var/ldap/ldap_client_cred</code> files</p>

**EXAMPLE 2** Forcing ldap\_cachemgr to Reread the /var/ldap/ldap\_client\_file and /var/ldap/ldap\_client\_cred Files (Continued)

```
example# pkill -HUP ldap_cachemgr
```

**FILES** /var/ldap/cachmgr.log Default log file.  
 /var/ldap/ldap\_client\_file  
 /var/ldap/ldap\_client\_cred Files containing the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use ldapclient(1M) to update these files.

**WARNINGS** The ldap\_cachemgr utility is included in the Solaris 9 release on an uncommitted basis only. It is subject to change or removal in a future minor release.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

**SEE ALSO** ldap(1), ldapadd(1), ldapdelete(1), ldaplist(1), ldapmodify(1), ldapmodrdn(1), ldapsearch(1), pkill(1), idsconfig(1M), ldapaddent(1M), ldapclient(1M), suninstall(1M), signal(3HEAD), resolv.conf(4), attributes(5)

## ldapclient(1M)

<b>NAME</b>	<code>ldapclient</code> – initialize LDAP client machine or output an LDAP client profile in LDIF format
<b>SYNOPSIS</b>	<pre><code>/usr/sbin/ldapclient [-v   -q] init [-a proxyName=profile] [-adomainName=domain] [-a proxyDN=proxyDN] [-a proxyPassword=password] [-a certificatePath=path] LDAP_server_addr [:port_number]  /usr/sbin/ldapclient [-v   -q] manual [-a attrName=attrVal]  /usr/sbin/ldapclient [-v   -q] mod [-a attrName=attrVal]  /usr/sbin/ldapclient [-v   -q] list  /usr/sbin/ldapclient [-v   -q] uninit  /usr/sbin/ldapclient [-v   -q] genprofile -a profileName=profileName [-a attrName=attrVal]</code></pre>
<b>DESCRIPTION</b>	<p>The <code>ldapclient</code> utility can be used to:</p> <ul style="list-style-type: none"><li>■ initialize LDAP client machines</li><li>■ restore the network service environment on LDAP clients</li><li>■ list the contents of the LDAP client cache in human readable format.</li></ul> <p>The <code>init</code> form of the <code>ldapclient</code> utility is used to initialize an LDAP client machine, using a profile stored on an LDAP server specified by <code>LDAP_server_addr</code>. The LDAP client will use the attributes in the specified profile to determine the configuration of the LDAP client. Using a configuration profile allows for easy installation of LDAP client and propagation of configuration changes to LDAP clients. The <code>ldap_cachemgr(1M)</code> utility will update the LDAP client configuration when its cache expires by reading the profile. For more information on the configuration profile refer to IETF document <i>A Configuration Schema for LDAP Based Directory User Agents</i>.</p> <p>The <code>manual</code> form of the <code>ldapclient</code> utility is used to initialize an LDAP client machine manually. The LDAP client will use the attributes specified on the command line. Any unspecified attributes will be assigned their default values. The <code>defaultSearchBase</code> and <code>defaultServerList</code> attributes must be specified, and the <code>domainName</code> attribute must be specified if the client's <code>domainName</code> is not set.</p> <p>The <code>mod</code> form of the <code>ldapclient</code> utility is used to modify the configuration of an LDAP client machine that was setup manually. This option modifies only those LDAP client configuration attributes specified on the command line. The <code>mod</code> option should only be used on LDAP clients that were initialized using the <code>manual</code> option.</p> <p>Regardless of which method is used for initialization, if a client is to be configured to use a proxy <code>credentialLevel</code>, proxy credentials must be provided using <code>-a proxyDN=proxyD</code> and <code>-a proxyPassword=proxyPassword</code> options. However, if <code>-a proxyPassword=proxyPassword</code> is not specified, <code>ldapclient</code> will prompt for it. Note that NULL passwords are not allowed in LDAP.</p>

If any file is modified during installation, it will be backed up to `/var/ldap/restore`. The files that are typically modified during initialization are:

- `/etc/nsswitch.conf`
- `/etc/defaultdomain` (if it exists)
- `/var/yp/binding/`domainname`` (for a NIS(YP) client)
- `/var/nis/NIS_COLD_START` (for a NIS+ client)
- `/var/ldap/ldap_client_file` (for an existing LDAP client)
- `/var/ldap/ldap_client_cred` (for an existing LDAP client)

`ldapclient` does not set up a client to resolve hostnames using DNS. It simply copies `/etc/nsswitch.ldap` to `/etc/nsswitch.conf`. If you prefer to use DNS for host resolution, please refer to the DNS documentation for information on setting up DNS. See `resolv.conf(4)`.

The `list` form of the `ldapclient` utility is used to list the LDAP client configuration. The output will be human readable. LDAP configuration files are not guaranteed to be human readable.

The `uninit` form of the `ldapclient` utility is used to uninitialized the network service environment, restoring it to the state it was in prior to the last execution of `ldapclient` using `init` or `manual`. The restoration will succeed only if the machine was initialized with the `init` or `manual` form of `ldapclient`, as it uses the backup files created by these options.

The `genprofile` option is used to write an LDIF formatted configuration profile based on the attributes specified on the command line to standard output. This profile can then be loaded into an LDAP server to be used as the client profile, which can be downloaded by means of the `ldapclient init` command. Loading the LDIF formatted profile to the directory server can be done through `ldapadd(1)`, or through any server specific import tool. Note that the attributes `proxyDN`, `proxyPassword`, `certificatePath`, and `domainName` are not part of the configuration profile and thus are not permitted.

You must have superuser privileges to run the `ldapclient` command, except with the `genprofile` option.

To access the information stored in the directory, clients can either authenticate to the directory, or use an unauthenticated connection. The LDAP client is configured to have a credential level of either `anonymous` or `proxy`. In the first case, the client does not authenticate to the directory. In the second case, client authenticates to the directory using a proxy identity.

If a client is configured to use an identity, you can configure which authentication method the client will use. The LDAP client supports the following authentication methods:

none

## ldapclient(1M)

```
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

Note that some directory servers may not support all of these authentication methods. For `simple`, be aware that the bind password will be sent in the clear to the LDAP server. For those authentication methods using TLS (transport layer security), the entire session is encrypted. You will need to install the appropriate certificate databases to use TLS.

### Commands

The following commands are supported:

<code>init</code>	Initialize client from a profile on a server.
<code>manual</code>	Manually initialize client with the specified attribute values.
<code>mod</code>	Modify attribute values in the configuration file after a manual initialization of the client.
<code>list</code>	Write the contents of the LDAP client cache to standard output in human readable form.
<code>uninit</code>	Uninitialize an LDAP client, assuming that <code>ldapclient</code> was used to initialize the client.
<code>genprofile</code>	Generate a configuration profile in LDIF format that can then be stored in the directory for clients to use, with the <code>init</code> form of this command.

### Attributes

The following attributes are supported:

#### `attributeMap`

Specify a mapping from an attribute defined by a service to an attribute in an alternative schema. This can be used to change the default schema used for a given service. The syntax of `attributeMap` is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is `NULL`. In the example,

```
attributeMap: passwd:uid=employeeNumber
```

the LDAP client would use the LDAP attribute `employeeNumber` rather than `uid` for the `passwd` service. This is a multivalued attribute.

#### `authenticationMethod`

Specify the default authentication method used by all services unless overridden by the `serviceAuthenticationMethod` attribute. Multiple values can be specified, using a comma-separated list. The default value is `none`. For those services that use `credentialLevel` and `credentialLevel` is `anonymous`, this attribute is

ignored. Services such as `pam_ldap` will use this attribute, even if `credentialLevel` is `anonymous`. The supported authentication methods are described above.

`bindTimeLimit`

The maximum time in seconds that a client should spend performing a bind operation. Set this to a positive integer. The default value is 30.

`certificatePath`

The certificate path for the location of the certificate database. The value is the path where security database files reside. This is used for TLS support, which is specified in the `authenticationMethod` and `serviceAuthenticationMethod` attributes. The default is `/var/ldap`.

`credentialLevel`

Specify the credential level the client should use to contact the directory. The credential levels supported are either `anonymous` or `proxy`. If a `proxy` credential level is specified, then the `authenticationMethod` attribute must be specified to determine the authentication mechanism. Further, if the credential level is `proxy` and at least one of the authentication methods require a bind DN, the `proxyDN` and `proxyPassword` attribute values must be set.

`defaultSearchBase`

Specify the default search base DN. There is no default. The `serviceSearchDescriptor` attribute can be used to override the `defaultSearchBase` for given services.

`defaultSearchScope=one | sub`

Specify the default search scope for the client's search operations. This default can be overridden for a given service by specifying a `serviceSearchDescriptor`. The default is one level search.

`domainName`

Specify the DNS domain name. This becomes the default domain for the machine. The default is the current domain name. This attribute is only used in client initialization.

`followReferrals=true | false`

Specify the referral setting. A setting of `true` implies that referrals will be automatically followed and `false` would result in referrals not being followed. The default is `true`.

`objectclassMap`

Specify a mapping from an `objectclass` defined by a service to an `objectclass` in an alternative schema. This can be used to change the default schema used for a given service. The syntax of `objectclassMap` is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is `NULL`. In the example,

```
objectclassMap=passwd:posixAccount=unixAccount
```

## ldapclient(1M)

the LDAP client would use the LDAP `objectclass` of `unixAccount` rather than the `posixAccount` for the `passwd` service. This is a multivalued attribute.

### `preferredServerList`

Specify the space separated list of preferred server IP addresses to be contacted before servers specified by the `defaultServerList` attribute. The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636. The default value for this attribute is no preferred servers.

### `profileName`

Specify the profile name. For `ldapclient init`, this attribute is the name of an existing profile which may be downloaded periodically depending on the value of the `profileTTL` attribute. For `ldapclient genprofile`, this is the name of the profile to be generated. The default value is `default`.

### `profileTTL`

Specify the TTL value in seconds for the client information. This is only relevant if the machine was initialized with a client profile. If you do not want `ldap_cachemgr(1M)` to attempt to refresh the LDAP client configuration from the LDAP server, set `profileTTL` to 0 (zero) . Valid values are either zero 0 (for no expiration) or a positive integer in seconds. The default value is 12 hours.

### `proxyDN`

Specify the Bind Distinguished Name for the proxy identity. This option is required if the credential level is `proxy`, and at least one of the authentication methods requires a bind DN. There is no default value.

### `proxyPassword`

Specify client proxy password. This option is required if the credential level is `proxy`, and at least one of the authentication methods requires a bind DN. There is no default.

### `searchTimeLimit`

Specify maximum number of seconds allowed for an LDAP search operation. The default is 30 seconds. The server may have its own search time limit.

### `serviceAuthenticationMethod`

Specify authentication methods to be used by a service. Multiple values can be specified by a comma-separated list. The default value is no service authentication methods, in which case, each service would default to the `authenticationMethod` value. The supported authentications are described above.

Three services support this feature: `passwd-cmd`, `keyserv`, and `pam_ldap`. The `passwd-cmd` service is used to define the authentication method to be used by `passwd(1)` to change the user's password and other attributes. The `keyserv` service is used to identify the authentication method to be used by the `chkey(1)` and `newkey(1M)` utilities. The `pam_ldap` service defines the authentication

## ldapclient(1M)

method to be used for authenticating users when `pam_ldap(5)` is configured. If this attribute is not set for any of these services, the `authenticationMethod` attribute is used to define the authentication method. This is a multivalued attribute.

### `serviceCredentialLevel`

Specify credential level to be used by a service. Multiple values can be specified in a space-separated list. The default value for all services is `NULL`. The supported credential levels are: `anonymous` or `proxy`. At present, no service uses this attribute. This is a multivalued attribute.

### `serviceSearchDescriptor`

Override the default base DN for LDAP searches for a given service. The format of the descriptors also allow overriding the default search scope and search filter for each service. The syntax of `serviceSearchDescriptor` is defined in the profile IETF draft. The default value for all services is `NULL`. This is a multivalued attribute. In the example,

```
serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one
```

the LDAP client would do a one level search in `ou=people,dc=a1,dc=acme,dc=com` rather than `ou=people, defaultSearchBase` for the `passwd` service.

**OPTIONS** The following options are supported:

- a Specify `attrName` and its value.
- q Quiet mode. No output is generated.
- v Verbose output.

**OPERANDS** The following operand is supported:

*defaultServerList* A space separated list of server IP addresses. The port number is optional. If not specified, the default LDAP server port number 389 is used except when TLS is specified in the authentication method, in which case the default LDAP server port number is 636.

**EXAMPLES** **EXAMPLE 1** Setting Up a Client By Using the Default Profile Stored on a Specified LDAP Server

The following example shows how to set up a client using the default profile stored on the specified LDAP server. This command will only be successful if either the credential level in the profile is set to `anonymous` or the authentication method is set to `none`.

```
example# ldapclient init 129.100.100.1
```

## ldapclient(1M)

### EXAMPLE 2 Setting Up a Client Using Only One Server

The following example shows how to set up a client using only one server. The authentication method is set to none, and the search base is `dc=mycompany,dc=com`.

```
example# ldapclient manual -a authenticationMethod=none \
-a defaultSearchBase=dc=mycompany,dc=com \
-a defaultServerList=129.100.100.1
```

### EXAMPLE 3 Setting Up a Client Using Only One Server That Does Not Follow Referrals

The following example shows how to set up a client using only one server. The credential level is set to proxy. The authentication method is `sasl/CRAM_MD5`, with the option not to follow referrals. The domain name is `xyz.mycompany.com`, and the LDAP server is running on port number 386 at IP address `129.100.100.1`.

```
example# ldapclient manual \
-a credentialLevel=proxy \
-a authenticationMethod=sasl/CRAM_MD5 \
-a proxyPassword=secret \
-a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com \
-a defaultSearchBase=dc=xyz,dc=mycompany,dc=com \
-a domainName=xyz.mycompany.com \
-a followReferrals=false \
-a defaultServerList=129.100.100.1:386
```

### EXAMPLE 4 Using `genprofile` to Set Only the `defaultSearchBase` and the Server Addresses

The following example shows how to use the `genprofile` command to set the `defaultSearchBase` and the server addresses.

```
example# ldapclient genprofile -a profileName=myprofile \
-a defaultSearchBase=dc=eng,dc=sun,dc=com \
-a "defaultServerList=129.100.100.1 129.100.234.15:386" \
> myprofile.ldif
```

### EXAMPLE 5 Creating a Profile That Overrides Every Default Value

The following example shows a profile that overrides every default value.

```
example# ldapclient genprofile -a profileName=eng \
-a credentialLevel=proxy -a authenticationMethod=sasl/DIGEST-MD5 \
-a bindTimeLimit=20 \
-a defaultSearchBase=dc=eng,dc=acme,dc=com \
-a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one" \
-a serviceAuthenticationMethod=pam_ldap:tls:simple \
-a defaultSearchScope=sub \
-a attributeMap=passwd:uid=employeeNumber \
-a objectclassMap=passwd:posixAccount=unixAccount \
-a followReferrals=false -a profileTTL=6000 \
-a preferredServerList=129.100.100.30 -a searchTimeLimit=30 \

link(1M)

**NAME** link, unlink – link and unlink files and directories

**SYNOPSIS** `/usr/sbin/link existing-file new-file`  
`/usr/xpg4/bin/link existing-file new-file`  
`/usr/sbin/unlink file`

**DESCRIPTION** The link and unlink commands link and unlink files and directories. Only super-users can use these commands.

Use link to create a new file that points to an existing file. The *existing-file* and *new-file* operands specify the existing file and newly-created files. See OPERANDS.

link and unlink directly invoke the link(2) and unlink(2) system calls, performing exactly what they are told to do and abandoning all error checking. This differs from the ln(1) command. See ln(1).

While linked files and directories can be removed using unlink, it is safer to use rm(1) and rmdir(1) instead. See rm(1) and rmdir(1).

**/usr/xpg4/bin/link** If the existing file being hard linked is itself a symbolic link, then the newly created file (*new-file*) will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself (*existing-file*).

**OPERANDS** *existing-file* Specifies the name of the existing file to be linked.  
*file* Specifies the name of the file to be unlinked.  
*new-file* Specifies the name of newly created (linked) file.

**ENVIRONMENT VARIABLES** See environ(5) for descriptions of the following environment variables that affect the execution of link: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

listen(1M)

<b>NAME</b>	listen – network listener daemon
<b>SYNOPSIS</b>	<code>/usr/lib/saf/listen [-m <i>devstem</i>] <i>net_spec</i></code>
<b>DESCRIPTION</b>	<p>The <code>listen</code> process “listens” to a network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any connection-oriented network (more precisely, with any connection-oriented transport provider) that conforms to the Transport Layer Interface (TLI) Specification.</p> <p>The listener internally generates a pathname for the minor device for each connection; it is this pathname that is used in the <code>utmpx</code> entry for a service, if one is created. By default, this pathname is the concatenation of the prefix <code>/dev/netspec</code> with the decimal representation of the minor device number. In either case, the representation of the minor device number will be at least two digits (for example, 05 or 27), or longer when it is necessary to accommodate minor device numbers larger than 99.</p>
<b>SERVER INVOCATION</b>	<p>When a connection indication is received, the listener creates a new transport endpoint and accepts the connection on that endpoint. Before giving the file descriptor for this new connection to the server, any designated STREAMS modules are pushed and the configuration script is executed, (if one exists). This file descriptor is appropriate for use with either TLI (see <code>t_sync(3NSL)</code> ) or the sockets interface library.</p> <p>By default, a new instance of the server is invoked for each connection. When the server is invoked, file descriptor 0 refers to the transport endpoint, and is open for reading and writing. File descriptors 1 and 2 are copies of file descriptor 0; no other file descriptors are open. The service is invoked with the user and group IDs of the user name under which the service was registered with the listener, and with the current directory set to the HOME directory of that user.</p> <p>Alternatively, a service may be registered so that the listener will pass connections to a standing server process through a FIFO or a named STREAM, instead of invoking the server anew for each connection. In this case, the connection is passed in the form of a file descriptor that refers to the new transport endpoint. Before the file descriptor is sent to the server, the listener interprets any configuration script registered for that service using <code>doconfig(3NSL)</code>, although <code>doconfig</code> is invoked with both the <code>NORUN</code> and <code>NOASSIGN</code> flags. The server receives the file descriptor for the connection in a <code>strrecvfd</code> structure using an <code>I_RECVFD ioctl(2)</code>.</p> <p>For more details about the listener and its administration, see <code>nlsadmin(1M)</code>.</p>
<b>OPTIONS</b>	<code>-mdevstem</code> The listener will use <i>devstem</i> as the prefix for the pathname.
<b>FILES</b>	<code>/etc/saf/pmtag/*</code>
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** nlsadmin(1M), pmadm(1M), sac(1M), sacadm(1M), ioctl(2), doconfig(3NSL), nlsgetcall(3NSL), nlsprovider(3NSL), t\_sync(3NSL), attributes(5), streamio(7I)

*System Administration Guide: Basic Administration*

**NOTES** When passing a connection to a standing server, the user and group IDs contained in the `strrecvfd` structure will be those for the listener (that is, they will both be 0); the user name under which the service was registered with the listener is not reflected in these IDs.

When operating multiple instances of the listener on a single transport provider, there is a potential race condition in the binding of addresses during initialization of the listeners, if any of their services have dynamically assigned addresses. This condition would appear as an inability of the listener to bind a static-address service to its otherwise valid address, and would result from a dynamic-address service having been bound to that address by a different instance of the listener.

## llc2\_loop(1M)

<b>NAME</b>	llc2_loop – loopback diagnostics to test the driver, adapter and network.
<b>SYNOPSIS</b>	<pre>/usr/lib/llc2/llc2_loop2 [-v] ppa /usr/lib/llc2/llc2_loop3 ppa sap frames /usr/lib/llc2/llc2_loop3 ppa type frames /usr/lib/llc2/llc2_loop4 [-v] ppa</pre>
<b>Loop 2</b>	<p>The loop2 test sends a NULL XID frame to the broadcast (all 1's) destination MAC address. The source SAP (Service Access Point) value used is 0x04 (SNA's SAP). Therefore, if SNA is running on the system, the loop2 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed, since the loop2 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The most likely error is:</p> <pre>Unexpected DLPI primitive x, expected y. where x = 5 and y = 6. From /usr/include/sys/dlpi.h, the expected return value from one of the DLPI primitives is 6 (DL_OK_ACK), but instead a 5 (DL_ERROR_ACK) was received. This can occur for two reasons:</pre> <ul style="list-style-type: none"><li>■ The loop2 command was issued to a non-existent PPA (Physical Point of Attachment).</li><li>■ The SAP (0x04) is already in use (for example, the SNA subsystem is up).</li></ul>
<b>Loop 3</b>	<p>The loop3 test sends 1,495 byte Unnumbered Information (UI) frames to the NULL (all 0's) destination MAC address. This should be used along with data capture either on the local node or another node on the same LAN to verify the transmission of data. The ppa argument specifies the adapter on which to run the test. The ppa is the relative physical position of the adapter and may be ascertained by viewing the adapter configuration (see llc2_config(1)). For Token Ring or Ethernet, specify an even sap value from 2 through 254, or, for Ethernet only, any type value from 1519 (0x05ef) through 65535 (0xffff). It is advised to pick a value that is easily recognized when the data capture output is viewed. frames is the decimal number of 1,495 bytes packets to transmit. The test will only display a message if a failure occurs.</p>
<b>Loop 4</b>	<p>The loop4 test sends a TEST frame (no information field) to the broadcast (all 1's) destination MAC address. The source SAP value used is 0x04 (SNA's SAP). Therefore, if SNA is running on the system, the loop4 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed since the loop4 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The loop4 test displays information similar to the following example if other nodes are listening and respond (verbose mode):</p> <pre>-Attaching -Binding</pre>

## llc2\_loop(1M)

```
-Sending TEST
-Responders
 1-0000c0c12449
 2-08000e142990
 3-08000e142a51
 4-0000c0450044
 5-0000c0199e46
-Unbinding
-Detaching
5 nodes responding
```

The errors displayed are the same as for `loop2`.

locator(1M)

**NAME** locator – location indicator control

**SYNOPSIS** `/usr/sbin/locator [-f | -n]`

**DESCRIPTION** The locator command sets or queries the state of the system locator if such a device exists.

Without options, the locator command reports the current state of the system.

The privileges required to use this command are hardware dependent. Typically, only the super user can get or set a locator.

**OPTIONS** The following options are supported:

-f Turns the locator off.

-n Turns the locator on.

**OPERANDS** The following operands are supported:

**EXAMPLES**

**EXAMPLE 1** Using the `locator` Command on a Platform Which Has a System Locator LED

When issued on a platform which has a system locator LED, the following command turns the locator on:

```
locator -n
locator
The 'system' locator is on
```

**EXAMPLE 2** Using the `locator` Command on a Platform Which Does Not Have a System Locator LED

When issued on a platform which does not have a system locator LED, the following command attempts to turn the locator on. The command returns an error message.

```
locator -n
'system' locator not found
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

1 Invalid command line input.

2 The requested operation failed.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

## lockd(1M)

<b>NAME</b>	lockd – network lock daemon				
<b>SYNOPSIS</b>	<code>/usr/lib/nfs/lockd [-g <i>graceperiod</i>] [-t <i>timeout</i>] [<i>nthreads</i>]</code>				
<b>DESCRIPTION</b>	<p>The <code>lockd</code> utility is part of the NFS lock manager, which supports record locking operations on NFS files. See <code>fcntl(2)</code> and <code>lockf(3C)</code>. The lock manager provides two functions:</p> <ul style="list-style-type: none"><li>■ it forwards <code>fcntl(2)</code> locking requests for NFS mounted file systems to the lock manager on the NFS server</li><li>■ it generates local file locking operations in response to requests forwarded from lock managers running on NFS client machines.</li></ul> <p>State information kept by the lock manager about these locking requests can be lost if the <code>lockd</code> is killed or the operating system is rebooted. Some of this information can be recovered as follows. When the server lock manager restarts, it waits for a grace period for all client-site lock managers to submit reclaim requests. Client-site lock managers, on the other hand, are notified by the status monitor daemon, <code>statd(1M)</code>, of the restart and promptly resubmit previously granted lock requests. If the lock daemon fails to secure a previously granted lock at the server site, then it sends SIGLOST to a process.</p>				
<b>OPTIONS</b>	<p><code>-g <i>graceperiod</i></code> Specify the number of seconds that clients have to reclaim locks after the server reboots. The default is 45 seconds.</p> <p><code>-t <i>timeout</i></code> Specify the number of seconds to wait before retransmitting a lock request to the remote server. The default value is 15 seconds.</p> <p><code><i>nthreads</i></code> Specify the maximum number of concurrent threads that the server can handle. This concurrency is achieved by up to <code><i>nthreads</i></code> threads created as needed in the kernel. <code><i>nthreads</i></code> should be based on the load expected on this server. If <code><i>nthreads</i></code> is not specified, the maximum number of concurrent threads will default to 20.</p>				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWnfscu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnfscu

<b>SEE ALSO</b>	<code>statd(1M)</code> , <code>fcntl(2)</code> , <code>lockf(3C)</code> , <code>attributes(5)</code>				

<b>NAME</b>	lockfs – change or report file system locks
<b>SYNOPSIS</b>	<code>/usr/sbin/lockfs [-adefhnuw] [-c <i>string</i>] [<i>file-system</i>...]</code>
<b>DESCRIPTION</b>	<p>lockfs is used to change and report the status of file system locks. lockfs reports the lock status and unlocks the file systems that were improperly left locked.</p> <p>Using lockfs to lock a file system is discouraged because this requires extensive knowledge of SunOS internals to be used effectively and correctly.</p> <p>When invoked with no arguments, lockfs lists the UFS file systems that are locked. If <i>file-system</i> is not specified, and -a is specified, lockfs is run on all mounted, UFS type file systems.</p> <p>The following options (described below) are mutually exclusive: wndheuf. If you do specify more than one of these options on a lockfs command line, the utility does not protest and invokes only the last option specified. In particular, you cannot specify a flush (-f) and a lock (for example, -w) on the same command line. However, all locking operations implicitly perform a flush, so the -f is superfluous when specifying a lock.</p>
<b>OPTIONS</b>	<p>The following options are supported. You must be super-user to use any of the following options, with the exception of -a.</p> <ul style="list-style-type: none"> <li>-a                   Apply command to all mounted, UFS type file systems. <i>file-system</i> is ignored when -a is specified.</li> <li>-c <i>string</i>        Accept a string that is passed as the comment field. The -c only takes affect when the lock is being set using the -d, -h, -n, -u, or -w options.</li> <li>-d                   delete-lock (dlock) the specified <i>file-system</i>. dlock suspends access that could remove directory entries.</li> <li>-e                   error-lock (elock) the specified <i>file-system</i>. elock blocks all local access to the locked file system and returns EWOULDBLOCK on all remote access. File systems are elocked by UFS on detection of internal inconsistency. They may only be unlocked after successful repair by fsck, which is usually done automatically (see mount_ufs(1M)). elocked file systems can be unmounted.</li> <li>-f                   Flush all transactions out of the log and write the transactions to the master file system. This option is valid only if logging has been enabled on the file system.</li> <li>-h                   Hard-lock (hlock) the specified <i>file-system</i>. hlock returns an error on every access to the locked file system, and cannot be unlocked. hlocked file systems can be unmounted.</li> <li>-n                   Name-lock (nlock) the specified <i>file-system</i>. nlock suspends accesses that could change or remove existing directories entries.</li> </ul>

## lockfs(1M)

- u Unlock (unlock) the specified *file-system*. unlock awakens suspended accesses.
- w Write-lock (wlock) the specified *file-system*. wlock suspends writes that would modify the file system. Access times are not kept while a file system is write-locked.

**OPERANDS** The following operands are supported.

*file-system* A list of path names separated by white spaces.

**USAGE** See `largefile(5)` for the description of the behavior of `lockfs` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** `lockfs` with the `-a` option.

In the following examples, *filesystem* is the pathname of the mounted-on directory (mount point). Locktype is one of "write," "name," "delete," "hard," or "unlock". When enclosed in parenthesis, the lock is being set. Comment is a string set by the process that last issued a lock command.

The following example shows the `lockfs` output when only the `-a` option is specified.

```
example# /usr/sbin/lockfs -a
```

Filesystem	Locktype	Comment
/	unlock	
/var	unlock	

```
example#
```

**EXAMPLE 2** `lockfs` with the `-w` option.

The following example shows the `lockfs` output when the `-w` option is used to write lock the `/var` file system and the comment string is set using the `-c` option. The `-a` option is then specified on a separate command line.

```
example# /usr/sbin/lockfs -w -c "lockfs: write lock example" /var
example# /usr/sbin/lockfs -a
```

Filesystem	Locktype	Comment
/	unlock	
/var	write	lockfs: write lock example

```
example#
```

**EXAMPLE 3** lockfs with the -u option.

The following example shows the lockfs output when the -u option is used to unlock the /var file system and the comment string is set using the -c option.

```
example# /usr/sbin/lockfs -uc "lockfs: unlock example" /var
example# /usr/sbin/lockfs /var
```

Filesystem	Locktype	Comment
/var	unlock	lockfs: unlock example

```
example#
```

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** kill(1), mount\_ufs(1M), fs\_ufs(4), attributes(5), largefile(5)

*System Administration Guide: Basic Administration*

**DIAGNOSTICS** *file system*: Not owner

You must be root to use this command.

*file system* :Deadlock condition detected/avoided

A file is enabled for accounting or swapping, on *file system*.

*file system*: Device busy

Another process is setting the lock on *file system*.

## lockstat(1M)

<b>NAME</b>	lockstat – report kernel lock and profiling statistics
<b>SYNOPSIS</b>	<b>lockstat</b> [-ACEHI] [-e <i>event_list</i> ] [-i <i>rate</i> ] [-b   -t   -h   -s <i>depth</i> ] [-n <i>nrecords</i> ] [-l <i>lock</i> [, <i>size</i> ]] [-d <i>duration</i> ] [-f <i>function</i> [, <i>size</i> ]] [-T] [-ckgwWRpP] [-D <i>count</i> ] [-o <i>filename</i> ] <i>command</i> [ <i>args</i> ]
<b>DESCRIPTION</b>	<p>The <code>lockstat</code> utility gathers and displays kernel locking and profiling statistics. <code>lockstat</code> allows you to specify which events to watch (for example, “spin on adaptive mutex,” “block on read access to rwlock due to waiting writers,” and so forth) how much data to gather for each event, and how to display the data. By default, <code>lockstat</code> monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.</p> <p><code>lockstat</code> gathers data until the specified command completes. For example, to gather statistics for a fixed-time interval, use <code>sleep(1)</code> as the command, as follows:</p> <pre>example# lockstat sleep 5</pre> <p>When the <code>-I</code> option is specified, <code>lockstat</code> establishes a per-processor high-level periodic interrupt source to gather profiling data. The interrupt handler simply generates a <code>lockstat</code> event whose “caller” is the interrupted PC (program counter). The profiling event is just like any other <code>lockstat</code> event, so all of the normal <code>lockstat</code> options are applicable.</p> <p><code>lockstat</code> relies on the <code>lockstat(7D)</code> driver, an exclusive-access device that modifies the running kernel’s text to intercept events of interest. This imposes a small but measurable overhead on all system activity, so access to the <code>lockstat(7D)</code> driver is restricted to super-user by default. The system administrator may relax this restriction by changing the permissions on <code>/dev/lockstat</code>.</p>
<b>Event selection options:</b>	<p><code>-C</code> Watch contention events.</p> <p><code>-E</code> Watch error events.</p> <p><code>-H</code> Watch hold events.</p> <p><code>-I</code> Watch profiling interrupt events.</p> <p><code>-A</code> Watch all lock events. <code>-A</code> is equivalent to <code>-CEH</code>.</p> <p><code>-e event_list</code> Only watch the specified events. <i>event list</i> is a comma-separated list of events or ranges of events such as <code>1,4-7,35</code>. Run <code>lockstat</code> with no arguments to get a brief description of all events.</p> <p><code>-i rate</code> Interrupt rate (per second) for <code>-I</code>. The default is 97 Hz, so that profiling doesn’t run in lockstep with the clock interrupt (which runs at 100 Hz).</p> <p>If no event selection options are specified, the default is <code>-CE</code>.</p>
<b>Data gathering options (mutually exclusive):</b>	<p><code>-b</code> Basic statistics: lock, caller, number of events.</p>

<b>Data filtering options:</b>	-t	Timing: Basic plus timing for all events [default].
	-h	Histogram: Timing plus time-distribution histograms.
	-s <i>depth</i>	Stack trace: Histogram plus stack traces up to <i>depth</i> frames deep.
	-n <i>nrecords</i>	Maximum number of data records.
	-l <i>lock[,size]</i>	Only watch <i>lock</i> , which can be specified as a symbolic name or hex address. <i>size</i> defaults to the ELF symbol size or 1 if the symbol size is not available.
	-f <i>func[,size]</i>	Only watch events generated by <i>func</i> , which can be specified as a symbolic name or hex address. <i>size</i> defaults to the ELF symbol size if available, or 1 if not.
	-d <i>duration</i>	Only watch events longer than <i>duration</i> .
<b>Data reporting options:</b>	-T	Trace (rather than sample) events [off by default].
	-c	Coalesce lock data for lock arrays (for example, <code>pse_mutex[]</code> ).
	-k	Coalesce PCs within functions.
	-g	Show total events generated by function. For example, if <code>foo()</code> calls <code>bar()</code> in a loop, the work done by <code>bar()</code> counts as work generated by <code>foo()</code> (along with any work done by <code>foo()</code> itself). The <code>-g</code> option works by counting the total number of stack frames in which each function appears. This implies two things: (1) the data reported by <code>-g</code> can be misleading if the stack traces are not deep enough, and (2) functions that are called recursively might show greater than 100% activity. In light of issue (1), the default data gathering mode when using <code>-g</code> is <code>-s 50</code> .
	-w	Wherever: distinguish events only by lock, not by caller.
	-W	Whichever: distinguish events only by caller, not by lock.
	-R	Display rates (events per second) rather than counts.
	-p	Parsable output format.
	-P	Sort data by ( <i>count * time</i> ) product.
	-D <i>count</i>	Only display the top <i>count</i> events of each type.
-o <i>filename</i>	Direct output to <i>filename</i> .	
<b>DISPLAY FORMATS</b>	The following headers appear over various columns of data.	
	Count or ops/s	Number of times this event occurred, or the rate (times per second) if <code>-R</code> was specified.
	indv	Percentage of all events represented by this individual event.
	genr	Percentage of all events generated by this function.

lockstat(1M)

cuml	Cumulative percentage; a running total of the individuals.
rcnt	Average reference count. This will always be 1 for exclusive locks (mutexes, spin locks, rwlocks held as writer) but may be greater than 1 for shared locks (rwlocks held as reader).
spin or nsec	Average number of times caller spun trying to get the lock, or average duration of the events in nanoseconds, as appropriate for the event. For the profiling event, "duration" means interrupt latency.
Lock	Address of the lock; displayed symbolically if possible.
CPU+PIL	CPU plus processor interrupt level (PIL). For example, if CPU 4 is interrupted while at PIL 6, this will be reported as cpu [4] +6.
Caller	Address of the caller; displayed symbolically if possible.

**EXAMPLES**

**EXAMPLE 1** Measuring kernel lock contention

example# **lockstat sleep 5**

Adaptive mutex spin: 2210 events in 5.055 seconds (437 events/sec)

Count	indv	cuml	rcnt	spin	Lock	Caller

### EXAMPLE 4 Basic kernel profiling

For basic profiling, we don't care whether the profiling interrupt sampled `foo()+0x4c` or `foo()+0x78`; we care only that it sampled somewhere in `foo()`, so we use `-k`. The CPU and PIL aren't relevant to basic profiling because we are measuring the system as a whole, not a particular CPU or interrupt level, so we use `-W`.

```
example# lockstat -kIW -D 20 ./polltest
Profiling interrupt: 82 events in 0.424 seconds (194
events/sec)
```

Count	indv	cuml	rcnt	nsec	Hottest	CPU+PIL	Caller

### EXAMPLE 5 Generated-load profiling

In the example above, 5% of the samples were in `poll()`. This tells us how much time was spent inside `poll()` itself, but tells us nothing about how much work was

**EXAMPLE 5** Generated-load profiling (Continued)

generated by `poll()`; that is, how much time we spent in functions called by `poll()`. To determine that, we use the `-g` option. The example below shows that although `polltest` spends only 5% of its time in `poll()` itself, `poll()`-induced work accounts for 34% of the load.

Note that the functions that generate the profiling interrupt (`lockstat_intr()`, `cyclic_fire()`, and so forth) appear in every stack trace, and therefore are considered to have generated 100% of the load. This illustrates an important point: the generated load percentages do *not* add up to 100% because they are not independent. If 72% of all stack traces contain both `foo()` and `bar()`, then both `foo()` and `bar()` are 72% load generators.

```
example# lockstat -kgIW -D 20 ./polltest
Profiling interrupt: 80 events in 0.412 seconds (194 events/sec)
```

Count	genr	cuml	rcnt	nsec	Hottest	CPU+PIL	Caller

3	4%	----	1.00	277	cpu[1]		polllock

. . .

**EXAMPLE 6** Gathering lock contention and profiling data for a specific module

In this example we use the `-f` option not to specify a single function, but rather to specify the entire text space of the `sbus` module. We gather both lock contention and profiling statistics so that contention can be correlated with overall load on the module.

```
example# modinfo | grep sbus
24 102a8b6f b8b4 59 1 sbus (SBus (sysio) nexus driver)
```

lockstat(1M)

**FILES** /dev/lockstat lockstat driver

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu (32-bit)
	SUNWcsxu (64-bit)

**SEE ALSO** `attributes(5)`, `lockstat(7D)`, `mutex(9F)`, `rwlock(9F)`

**NOTES** The profiling support provided by `lockstat -I` replaces the old (and undocumented) `/usr/bin/kgmon` and `/dev/profile`.

Tail-call elimination may affect call sites. For example, if `foo() + 0x50` calls `bar()` and the last thing `bar()` does is call `mutex_exit()`, the compiler may arrange for `bar()` to branch to `mutex_exit()` with a return address of `foo() + 0x58`. Thus, the `mutex_exit()` in `bar()` will appear as though it occurred at `foo() + 0x58`.

The PC in the stack frame in which an interrupt occurs may be bogus because, between function calls, the compiler is free to use the return address register for local storage.

When using the `-I` and `-s` options together, the interrupted PC will usually not appear anywhere in the stack since the interrupt handler is entered asynchronously, not by a function call from that PC.

The `lockstat` technology is provided on an as-is basis. The format and content of `lockstat` output reflect the current Solaris kernel implementation and are therefore subject to change in future releases.

## lofiadm(1M)

<b>NAME</b>	lofiadm – administer files available as block devices through lofi
<b>SYNOPSIS</b>	<pre>/usr/sbin/lofiadm -a file [device] /usr/sbin/lofiadm -d file   device /usr/sbin/lofiadm [ file   device]</pre>
<b>DESCRIPTION</b>	<p>lofiadm administers lofi(7D), the loopback file driver. lofi(7D) allows a file to be associated with a block device. That file can then be accessed through the block device. This is useful when the file contains an image of some filesystem (such as a floppy or CD-ROM image), because the block device can then be used with the normal system utilities for mounting, checking or repairing filesystems. See fsck(1M) and mount(1M).</p> <p>Use lofiadm to add a file as a loopback device, remove such an association, or print information about the current associations.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><i>-a file [device]</i>      Add <i>file</i> as a block device.</p> <p>                          If <i>device</i> is not specified, an available device is picked.</p> <p>                          If <i>device</i> is specified, lofiadm attempts to assign it to <i>file</i>. <i>device</i> must be available or lofiadm will fail. The ability to specify a device is provided for use in scripts that wish to re-establish a particular set of associations.</p> <p><i>-d file   device</i>      Remove an association by <i>file</i> or <i>device</i> name, if the associated block device is not busy, and deallocates the block device.</p>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>file</i>                    Print the block device associated with <i>file</i>.</p> <p><i>device</i>                Print the file name associated with the block device <i>device</i>.</p> <p>                          Without arguments, print a list of the current associations. Filenames must be valid absolute pathnames.</p> <p>                          When a file is added, it is opened for reading or writing by root. Any restrictions apply (such as restricted root access over NFS). The file is held open until the association is removed. It is not actually accessed until the block device is used, so it will never be written to if the block device is only opened read-only.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Mounting an Existing CD-ROM Image</p> <p>You should ensure that Solaris understands the image before creating the CD. lofi allows you to mount the image and see if it works.</p>

**EXAMPLE 1** Mounting an Existing CD-ROM Image (Continued)

This example mounts an existing CD-ROM image (`sparc.iso`), of the Red Hat 6.0 CD which was downloaded from the Internet. It was created with the `mkisofs` utility from the Internet.

Use `lofiadm` to attach a block device to it:

```
lofiadm -a /home/mike_s/RH6.0/sparc.iso
/dev/lofi/1
```

`lofiadm` picks the device and prints the device name to the standard output. You can run `lofiadm` again by issuing the following command:

```
lofiadm
Block Device File
/dev/lofi/1 /home/mike_s/RH6.0/sparc.iso
```

Or, you can give it one name and ask for the other, by issuing the following command:

```
lofiadm /dev/lofi/1
/home/mike_s/RH6.0/sparc.iso
```

Use the `mount` command to mount the image:

```
mount -F hsfs -o ro /dev/lofi/1 /mnt
```

Check to ensure that Solaris understands the image:

```
df -k /mnt
Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 512418 512418 0 100% /mnt
ls /mnt
./ RedHat/ doc/ ls-lR rr_moved/
../ TRANS.TBL dosutils/ ls-lR.gz sbin@
.buildlog bin@ etc@ misc/ tmp/
COPYING boot/ images/ mnt/ usr@
README boot.cat* kernels/ modules/
RPM-PGP-KEY dev@ lib@ proc/
```

Solaris can mount the CD-ROM image, and understand the filenames. The image was created properly, and you can now create the CD-ROM with confidence.

As a final step, unmount and detach the images:

```
umount /mnt
lofiadm -d /dev/lofi/1
lofiadm
Block Device File
```

**EXAMPLE 2** Mounting a Floppy Image

This is similar to Example 1.

**EXAMPLE 2** Mounting a Floppy Image *(Continued)*

Using `lofi` to help you mount files that contain floppy images is helpful if a floppy disk contains a file that you need, but the machine which you're on doesn't have a floppy drive. It is also helpful if you don't want to take the time to use the `dd` command to copy the image to a floppy.

This is an example of getting to MDB floppy for Solaris x86:

```
lofiadm -a /export/s28/MDB_s28x_wos/latest/boot.3
/dev/lofi/1
mount -F pcfs /dev/lofi/1 /mnt
ls /mnt
./ COMMENT.BAT* RC.D/ SOLARIS.MAP*
../ IDENT* REPLACE.BAT* X/
APPEND.BAT* MAKEDIR.BAT* SOLARIS/
umount /mnt
lofiadm -d /export/s28/MDB_s28x_wos/latest/boot.3
```

**EXAMPLE 3** Making a UFS Filesystem on a File

Making a UFS filesystem on a file can be useful, particularly if a test suite requires a scratch filesystem. It can be painful (or annoying) to have to re-partition a disk just for the test suite, but you don't have to. You can `newfs` a file with `lofi`

Create the file:

```
mkfile 35m /export/home/test
```

Attach it to a block device. You also get the character device that `newfs` requires, so `newfs` that:

```
lofiadm -a /export/home/test
/dev/lofi/1
newfs /dev/rlofi/1
newfs: construct a new file system /dev/rlofi/1: (y/n)? y
/dev/rlofi/1: 71638 sectors in 119 cylinders of 1 tracks, 602 sectors
 35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
 32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,
```

Note that `ufs` might not be able to use the entire file. Mount and use the filesystem:

```
mount /dev/lofi/1 /mnt
df -k /mnt
Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 33455 9 30101 1% /mnt
ls /mnt
./ ../ lost+found/
umount /mnt
lofiadm -d /dev/lofi/1
```

**EXAMPLE 4** Creating a PC (FAT) File System on a Unix File

The following series of commands creates a FAT file system on a Unix file. The file is associated with a block device created by `lofiadm`.

```
mkfile 10M /export/test/testfs
lofiadm -a /export/test testfs
/dev/lofi/1
Note use of rlofi, not lofi, in following command.
mkfs -F pcfs -o nofdisk,size=20480 /dev/rlofi/1
Construct a new FAT file system on /dev/rlofi/1: (y/n)? y
mount -F pcfs /dev/lofi/1 /mnt
cd /mnt
df -k .
Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 10142 0 10142 0% /mnt
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `lofiadm`: `LC_CTYPE`, `LC_MESSAGES` and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

```
0 Successful completion.
>0 An error occurred.
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO**

`fsck(1M)`, `mount(1M)`, `mount_ufs(1M)`, `attributes(5)`, `lofi(7D)`, `lofs(7FS)`

**NOTES**

Just as you would not directly access a disk device that has mounted file systems, you should not access a file associated with a block device except through the `lofi` file driver. It might also be appropriate to ensure that the file has appropriate permissions to prevent such access.

Associations are not persistent across reboots. A script can be used to re-establish them if required.

The abilities of `lofiadm`, and who can use them, are controlled by the permissions of `/dev/lofictl`. Read-access allows query operations, such as listing all the associations. Write-access is required to do any state-changing operations, like adding an association. As shipped, `/dev/lofictl` is owned by `root`, in group `sys`, and mode `0644`, so all users can do query operations but only `root` can change anything. The administrator can give users write-access, allowing them to add or delete associations, but that is very likely a security hole and should probably only be given to a trusted group.

## lofiadm(1M)

When mounting a filesystem image, take care to use appropriate mount options. In particular, the `nosuid` mount option might be appropriate for UFS images whose origin is unknown. Also, some options might not be useful or appropriate, like `logging` or `forcedirectio` for UFS. For compatibility purposes, a raw device is also exported along with the block device. For example, `newfs(1M)` requires one.

The output of `lofiadm` (without arguments) might change in future releases.

<b>NAME</b>	logins – list user and system login information
<b>SYNOPSIS</b>	<code>/usr/bin/logins</code> [-admopstux] [-g <i>group...</i> ] [-l <i>login...</i> ]
<b>DESCRIPTION</b>	This command displays information on user and system logins known to the system. Contents of the output is controlled by the command options and can include the following: user or system login, user id number, passwd account field value (user name or other information), primary group name, primary group id, multiple group names, multiple group ids, home directory, login shell, and four password aging parameters. The default information is the following: login id, user id, primary group name, primary group id and the account field value. Output is sorted by user id, system logins, followed by user logins.
<b>OPTIONS</b>	<p>The following options are supported:</p> <p>Options may be used together. If so, any login that matches any criteria will be displayed.</p> <ul style="list-style-type: none"> <li>-a           Add two password expiration fields to the display. The fields show how many days a password can remain unused before it automatically becomes inactive, and the date that the password will expire.</li> <li>-d           Selects logins with duplicate uids.</li> <li>-m           Displays multiple group membership information.</li> <li>-o           Formats output into one line of colon-separated fields.</li> <li>-p           Selects logins with no passwords.</li> <li>-s           Selects all system logins.</li> <li>-t           Sorts output by login instead of by uid.</li> <li>-u           Selects all user logins.</li> <li>-x           Prints an extended set of information about each selected user. The extended information includes home directory, login shell and password aging information, each displayed on a separate line. The password information consists of password status (PS for password, NP for no password or LK for locked). If the login is passworded, status is followed by the date the password was last changed, the number of days required between changes, and the number of days allowed before a change is required. The password aging information shows the time interval that the user will receive a password expiration warning message (when logging on) before the password expires.</li> <li>-g <i>group</i>   Selects all users belonging to <i>group</i>, sorted by login. Multiple groups can be specified as a comma-separated list. When the -l and -g options are combined, a user will only be listed once, even if the user belongs to more than one of the selected groups.</li> </ul>

## logins(1M)

`-l login` Selects the requested login. Multiple logins can be specified as a comma-separated list. Depending on the nameservice lookup types set in `/etc/nsswitch.conf`, the information can come from the `/etc/passwd` and `/etc/shadow` files and other nameservices. When the `-l` and `-g` options are combined, a user will only be listed once, even if the user belongs to more than one of the selected groups.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `attributes(5)`

<b>NAME</b>	lpadmin – configure the LP print service
<b>SYNOPSIS</b>	<pre>lpadmin -p <i>printer options</i> lpadmin -x <i>dest</i> lpadmin -d [<i>dest</i>] lpadmin -S <i>print-wheel</i> -A <i>alert-type</i> [-W <i>minutes</i>] [-Q <i>requests</i>] lpadmin -M -f <i>form-name</i> [-a [-o <i>filebreak</i>] [-t <i>tray-number</i>]]</pre>
<b>DESCRIPTION</b>	<p>lpadmin configures the LP print service by defining printers and devices. It is used to add and change printers, to remove printers from service, to set or change the system default destination, to define alerts for printer faults, and to mount print wheels.</p>
<b>Adding or Changing a Printer</b>	<p>The first form of the lpadmin command (<code>lpadmin -p <i>printer options</i></code>) is used to configure a new printer or to change the configuration of an existing printer. When creating a new printer, one of three options (<code>-v</code>, <code>-U</code>, or <code>-s</code>) must be supplied. In addition, only one of the following may be supplied: <code>-e</code>, <code>-i</code>, or <code>-m</code>; if none of these three options is supplied, the model standard is used. The <code>-h</code> and <code>-l</code> options are mutually exclusive. Printer and class names may be no longer than 14 characters and must consist entirely of the characters A-Z, a-z, 0-9, dash (-) and underscore (_). If <code>-s</code> is specified, the following options are invalid: <code>-A</code>, <code>-e</code>, <code>-F</code>, <code>-h</code>, <code>-i</code>, <code>-l</code>, <code>-M</code>, <code>-m</code>, <code>-o</code>, <code>-U</code>, <code>-v</code>, and <code>-W</code>.</p> <p>The following <i>printer options</i> may appear in any order.</p> <p><code>-A <i>alert-type</i> [-W <i>minutes</i>]</code></p> <p>The <code>-A</code> option is used to define an alert that informs the administrator when a printer fault is detected, and periodically thereafter, until the printer fault is cleared by the administrator. The <i>alert-types</i> are:</p> <p><code>mail</code> Send the alert message using mail (see mail(1)) to the administrator.</p> <p><code>write</code> Write the message to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is chosen arbitrarily.</p> <p><code>quiet</code> Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the fault has been cleared and printing resumes, messages will again be sent when another fault occurs with the printer.</p> <p><code>showfault</code> Attempt to execute a fault handler on each system that has a print job in the queue. The fault handler is <code>/etc/lp/alerts/printer</code>. It is invoked with three parameters: <i>printer_name</i>, <i>date</i>, <i>file_name</i>. The <i>file_name</i> is the name of a file containing the fault message.</p>

`none`

Do not send messages; any existing alert definition for the printer will be removed. No alert will be sent when the printer faults until a different alert-type (except `quiet`) is used.

*shell-command*

Run the *shell-command* each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the `mail` and `write` values for this option are equivalent to the values `mail user-name` and `write user-name` respectively, where *user-name* is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the `su` command to change to another user ID. If the `su` command has been used to change the user ID, then the *user-name* for the new ID is used.

`list`

Display the type of the alert for the printer fault. No change is made to the alert.

The message sent appears as follows:

```
The printer printer has stopped printing for the reason given below.
Fix the problem and bring the printer back on line.
Printing has stopped, but will be restarted in a few minutes;
issue an enable commant if you want to restart sooner.
```

Unless someone issues the change request:

```
lp -i request-id -P ...to change the page list to print, the current request will be
reprinted from the beginning. The reason(s) it stopped (multiple reasons indicate
reprinted attempts):reason
```

The LP print service can detect printer faults only through an adequate fast filter and only when the standard interface program or a suitable customized interface program is used. Furthermore, the level of recovery after a fault depends on the capabilities of the filter.

If the *printer* is `all`, the alerting defined in this command applies to all existing printers.

If the `-W` option is not used to arrange fault alerting for *printer*, the default procedure is to mail one message to the administrator of *printer* per fault. This is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than zero, an alert will be sent at intervals specified by *minutes*.

`-c class`

Insert *printer* into the specified *class*. *class* will be created if it does not already exist.

**-D *comment***

Save this *comment* for display whenever a user asks for a full description of *printer* (see `lpstat(1)`). The LP print service does not interpret this comment.

**-e *printer***

Copy the interface program of an existing *printer* to be the interface program for *printer*. (Options `-i` and `-m` may not be specified with this option.)

**-F *fault-recovery***

This option specifies the recovery to be used for any print request that is stopped because of a printer fault, according to the value of *fault-recovery*:

`continue`      Continue printing on the top of the page where printing stopped. This requires a filter to wait for the fault to clear before automatically continuing.

`beginning`     Start printing the request again from the beginning.

`wait`            Disable printing on *printer* and wait for the administrator or a user to enable printing again.

During the wait, the administrator or the user who submitted the stopped print request can issue a change request that specifies where printing should resume. (See the `-i` option of the `lp` command.) If no change request is made before printing is enabled, printing resumes at the top of the page where stopped, if the filter allows; otherwise, the request is printed from the beginning.

**-f *allow:form-list*****-f *deny:form-list***

Allow or deny the forms in *form-list* to be printed on *printer*. By default no forms are allowed on a new printer.

For each printer, the LP print service keeps two lists of forms: an “allow-list” of forms that may be used with the printer, and a “deny-list” of forms that may not be used with the printer. With the `-f allow` option, the forms listed are added to the allow-list and removed from the deny-list. With the `-f deny` option, the forms listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the forms in the list may be used on the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the forms in the deny-list may not be used with the printer. All forms can be excluded from a printer by specifying `-f deny:all`. All forms can be used on a printer (provided the printer can handle all the characteristics of each form) by specifying `-f allow:all`.

The LP print service uses this information as a set of guidelines for determining where a form can be mounted. Administrators, however, are not restricted from mounting a form on any printer. If mounting a form on a particular printer is in

## lpadmin(1M)

disagreement with the information in the allow-list or deny-list, the administrator is warned but the mount is accepted. Nonetheless, if a user attempts to issue a print or change request for a form and printer combination that is in disagreement with the information, the request is accepted only if the form is currently mounted on the printer. If the form is later unmounted before the request can print, the request is canceled and the user is notified by mail.

If the administrator tries to specify a form as acceptable for use on a printer that doesn't have the capabilities needed by the form, the command is rejected.

Note the other use of `-f`, with the `-M` option, below.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-f` option can be used.

`-h`

Indicate that the device associated with the printer is hardwired. If neither of the mutually exclusive options, `-h` and `-l`, is specified, `-h` is assumed.

`-I content-type-list`

Allow *printer* to handle print requests with the content types listed in a *content-type-list*. If the list includes names of more than one type, the names must be separated by commas or blank spaces. (If they are separated by blank spaces, the entire list must be enclosed in double quotes.)

The type `simple` is recognized as the default content type for files in the UNIX system. A `simple` type of file is a data stream containing only printable ASCII characters and the following control characters:

Control Character	Octal Value	Meaning
BACKSPACE	10	move back one character, except at beginning of line
TAB	11	move to next tab stop
LINEFEED (newline)	12	move to beginning of next line
FORMFEED	14	move to beginning of next page
RETURN	15	move to beginning of current line

To prevent the print service from considering `simple` a valid type for the printer, specify either an explicit value (such as the printer type) in the *content-type-list*, or an empty list. If you do want `simple` included along with other types, you must include `simple` in the *content-type-list*.

In addition to content types defined by the print administrator, the type `PostScript` is recognized and supported by the Solaris print subsystem. This includes filters to support `PostScript` as the printer content type.

The type `any` is recognized as a special content type for files. When declared as the input type for a printer, it signals the print sub-system not to do any filtering on the file before sending it to the printer.

Except for `simple` and `any`, each *content-type* name is freely determined by the administrator. If the printer type is specified by the `-T` option, then the printer type is implicitly considered to be also a valid content type.

`-i interface`

Establish a new interface program for *printer*. *interface* is the pathname of the new program. (The `-e` and `-m` options may not be specified with this option.)

`-l`

Indicate that the device associated with *printer* is a login terminal. The LP scheduler (`lpsched`) disables all login terminals automatically each time it is started. (The `-h` option may not be specified with this option.)

`-M -f form-name [-a [ -o filebreak]] [-t tray-number]`

Mount the form *form-name* on *printer*. Print requests that need the pre-printed form *form-name* will be printed on *printer*. If more than one printer has the form mounted and the user has specified `any` (with the `-d` option of the `lp` command) as the printer destination, then the print request will be printed on the one printer that also meets the other needs of the request.

The page length and width, and character and line pitches needed by the form are compared with those allowed for the printer, by checking the capabilities in the `terminfo` database for the type of printer. If the form requires attributes that are not available with the printer, the administrator is warned but the mount is accepted. If the form lists a print wheel as mandatory, but the print wheel mounted on the printer is different, the administrator is also warned but the mount is accepted.

If the `-a` option is given, an alignment pattern is printed, preceded by the same initialization of the physical printer that precedes a normal print request, with one exception: no banner page is printed. Printing is assumed to start at the top of the first page of the form. After the pattern is printed, the administrator can adjust the mounted form in the printer and press return for another alignment pattern (no initialization this time), and can continue printing as many alignment patterns as desired. The administrator can quit the printing of alignment patterns by typing `q`.

If the `-o filebreak` option is given, a formfeed is inserted between each copy of the alignment pattern. By default, the alignment pattern is assumed to correctly fill a form, so no formfeed is added.

If the `-t tray-number` option is specified, printer tray *tray-number* will be used.

## lpadmin(1M)

A form is “unmounted” either by mounting a new form in its place or by using the `-f none` option. By default, a new printer has no form mounted.

Note the other use of `-f` without the `-M` option above.

### `-M -S print-wheel`

Mount the *print-wheel* on *printer*. Print requests that need the *print-wheel* will be printed on *printer*. If more than one printer has *print-wheel* mounted and the user has specified any (with the `-d` option of the `lp` command) as the printer destination, then the print request will be printed on the one printer that also meets the other needs of the request.

If the *print-wheel* is not listed as acceptable for the printer, the administrator is warned but the mount is accepted. If the printer does not take print wheels, the command is rejected.

A print wheel is “unmounted” either by mounting a new print wheel in its place or by using the option `-S none`. By default, a new printer has no print wheel mounted.

Note the other uses of the `-S` option without the `-M` option described below.

### `-m model`

Select *model* interface program, provided with the LP print service, for the printer. (Options `-e` and `-i` may not be specified with this option.)

### `-o option`

The `-o` option defines default printer configuration values given to an interface program. The default may be explicitly overwritten for individual requests by the user (see `lp(1)`), or taken from a preprinted form description (see `lpforms(1M)` and `lp(1)`).

There are several options which are pre-defined by the system. In addition, any number of key-value pairs may be defined. Each of the predefined and undefined options are described.

#### The Predefined Options

The following options are predefined: adjusting printer capabilities, adjusting printer port characteristics, configuring network printers, and controlling the use of banner.

#### Adjusting Printer Capabilities

```
length=scaled-decimal-number
width=scaled-decimal-number
cpi=scaled-decimal-number
lpi=scaled-decimal-number
```

The term *scaled-decimal-number* refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter attached to the number.

Three types of *scaled-decimal-numbers* can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing *c*); numbers that show sizes in inches (marked with a trailing *i*); and numbers that show sizes in units appropriate to use (without a trailing letter), that is, lines, characters, lines per inch, or characters per inch.

The option values must agree with the capabilities of the type of physical printer, as defined in the terminfo database for the printer type. If they do not, the command is rejected.

The defaults are defined in the terminfo entry for the specified printer type. The defaults may be reset by:

```
lpadmin -p printername -o length=
lpadmin -p printername -o width=
lpadmin -p printername -o cpi=
lpadmin -p printername -o lpi=
```

#### Adjusting Printer Port Characteristics

```
stty="' stty-option-list' "
```

The *stty-option-list* is not checked for allowed values, but is passed directly to the stty program by the standard interface program. Any error messages produced by stty when a request is processed (by the standard interface program) are mailed to the user submitting the request.

The default for stty is:

```
stty="'9600 cs8 -cstopb -parenb ixon
-ixany opost -olcuc onlcr
-ocrnl -onocr
-onlret -ofill nl0 cr0 tab0 bs0 vt0 ff0'"
```

The default may be reset by:

```
lpadmin -p printername -o stty=
```

#### Configuring Network Printers

```
dest=string
protocol=string
bsdctrl=string
timeout=non-negative-integer-seconds
```

These four options are provided to support network printing. Each option is passed directly to the interface program; any checking for allowed values is done there.

The value of *dest* is the name of the destination for the network printer; the semantics for value *dest* are dependent on the printer and the configuration. There is no default.

The value of option *protocol* sets the over-the-wire protocol to the printer. The default for option *protocol* is *bsd*. The value of option *bsdctrl* sets the print

## lpadmin(1M)

order of control and data files (BSD protocol only); the default for this option is control file first. The value of option timeout sets the seed value for backoff time when the printer is busy. The default value for the timeout option is 10 seconds. The defaults may be reset by:

```
lpadmin -p printername -o protocol=
lpadmin -p printername -o bsdctrl=
lpadmin -p printername -o timeout=
```

### Controlling the Use of the Banner Page

nobanner

Allow a user to submit a print request specifying that no banner page be printed.

banner

Force a banner page to be printed with every print request, even when a user asks for no banner page. This is the default. Specify `-o nobanner` to allow users to specify `-o nobanner` with the `lp` command. Undefined Options

### *key=value*

Each *key=value* is passed directly to the interface program. Any checking for allowed values is done in the interface program.

Any default values for a given *key=value* option are defined in the interface program. If a default is provided, it may be reset by typing the key without any value:

```
lpadmin -p printername -o key=
```

### `-P paper-name`

Specify a paper type list that the printer supports.

### `-r class`

Remove *printer* from the specified *class*. If *printer* is the last member of *class*, then *class* will be removed.

### `-S list`

Allow either the print wheels or aliases for character sets named in *list* to be used on the printer.

If the printer is a type that takes print wheels, then *list* is a comma or space separated list of print wheel names. (Enclose the list with quotes if it contains blank spaces.) These will be the only print wheels considered mountable on the printer. (You can always force a different print wheel to be mounted.) Until the option is used to specify a list, no print wheels will be considered mountable on the printer, and print requests that ask for a particular print wheel with this printer will be rejected.

If the printer is a type that has selectable character sets, then *list* is a comma or blank separated list of character set name "mappings" or aliases. (Enclose the list with quotes if it contains blank spaces.) Each "mapping" is of the form *known-name=alias*. The *known-name* is a character set number preceded by *cs* (such

as `cs3` for character set three) or a character set name from the `terminfo` database entry `csnm`. See `terminfo(4)`. If this option is not used to specify a list, only the names already known from the `terminfo` database or numbers with a prefix of `cs` will be acceptable for the printer. If *list* is the word `none`, any existing print wheel lists or character set aliases will be removed.

Note the other uses of the `-S` with the `-M` option described above.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-S` option can be used.

`-s system-name[ !printer-name]`

Make a remote printer (one that must be accessed through another system) accessible to users on your system. *system-name* is the name of the remote system on which the remote printer is located it. *printer-name* is the name used on the remote system for that printer. For example, if you want to access *printer1* on *system1* and you want it called *printer2* on your system:

```
-p printer2 -s system1 !printer1
```

`-T printer-type-list`

Identify the printer as being of one or more *printer-types*. Each *printer-type* is used to extract data from the `terminfo` database; this information is used to initialize the printer before printing each user's request. Some filters may also use a *printer-type* to convert content for the printer. If this option is not used, the default *printer-type* will be unknown; no information will be extracted from `terminfo` so each user request will be printed without first initializing the printer. Also, this option must be used if the following are to work: `-o cpi`, `-o lpi`, `-o width`, and `-o length` options of the `lpadmin` and `lp` commands, and the `-S` and `-f` options of the `lpadmin` command.

If the *printer-type-list* contains more than one type, then the *content-type-list* of the `-I` option must either be specified as `simple`, as empty (`-I ""`), or not specified at all.

`-t number-of-trays`

Specify the number of trays when creating the printer.

`-u allow:login-ID-list`

`-u deny:login-ID-list`

Allow or deny the users in *login-ID-list* access to the printer. By default all users are allowed on a new printer. The *login-ID-list* argument may include any or all of the following constructs:

<i>login-ID</i>	a user on any system
<i>system-name</i> ! <i>login-ID</i>	a user on system <i>system-name</i>
<i>system-name</i> !all	all users on system <i>system-name</i>

## lpadmin(1M)

<code>all!login-ID</code>	a user on all systems
<code>all</code>	all users on all systems

For each printer, the LP print service keeps two lists of users: an “allow-list” of people allowed to use the printer, and a “deny-list” of people denied access to the printer. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the users in the list may use the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the users in the deny-list may not use the printer. All users can be denied access to the printer by specifying `-u deny:all`. All users may use the printer by specifying `-u allow:all`.

### `-U dial-info`

The `-U` option allows your print service to access a remote printer. (It does not enable your print service to access a remote printer service.) Specifically, `-U` assigns the “dialing” information *dial-info* to the printer. *dial-info* is used with the `dial` routine to call the printer. Any network connection supported by the Basic Networking Utilities will work. *dial-info* can be either a phone number for a modem connection, or a system name for other kinds of connections. Or, if `-U direct` is given, no dialing will take place, because the name `direct` is reserved for a printer that is directly connected. If a system name is given, it is used to search for connection details from the file `/etc/uucp/Systems` or related files. The Basic Networking Utilities are required to support this option. By default, `-U direct` is assumed.

### `-v device`

Associate a *device* with *printer*. *device* is the path name of a file that is writable by `lp`. Note that the same *device* can be associated with more than one printer.

### Removing a Printer Destination

The `-x dest` option removes the destination *dest* (a printer or a class), from the LP print service. If *dest* is a printer and is the only member of a class, then the class will be deleted, too. If *dest* is `all`, all printers and classes are removed. No other *options* are allowed with `-x`.

### Setting/Changing the System Default Destination

The `-d [dest]` option makes *dest* (an existing printer or class) the new system default destination. If *dest* is not supplied, then there is no system default destination. No other *options* are allowed with `-d`.

### Setting an Alert for a Print Wheel

`-S print-wheel -A alert-type [-W minutes] [-Q requests]`

The `-S print-wheel` option is used with the `-A alert-type` option to define an alert to mount the print wheel when there are jobs queued for it. If this command is not used to arrange alerting for a print wheel, no alert will be sent for the print wheel. Note the other use of `-A`, with the `-p` option, above.

The *alert-types* are:

<code>mail</code>	Send the alert message using the <code>mail</code> command to the administrator.
<code>write</code>	Write the message, using the <code>write</code> command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.
<code>quiet</code>	Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the <i>print-wheel</i> has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the <code>-Q</code> option.
<code>none</code>	Do not send messages until the <code>-A</code> option is given again with a different <i>alert-type</i> (other than <code>quiet</code> ).
<code>shell-command</code>	Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blanks embedded in the command, enclose the command in quotes. Note that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values <code>mail user-name</code> and <code>write user-name</code> respectively, where <i>user-name</i> is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the <code>su</code> command to change to another user ID. If the <code>su</code> command has been used to change the user ID, then the <i>user-name</i> for the new ID is used.
<code>list</code>	Display the type of the alert for the print wheel on standard output. No change is made to the alert.

The message sent appears as follows:

```
The print wheel print-wheel needs to be mounted
on the printer(s):
printer (integer1requests) integer2 print requests
await this print wheel.
```

The printers listed are those that the administrator had earlier specified were candidates for this print wheel. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the printer list is the total number of requests awaiting the print wheel. It will be less than the sum of the other numbers if some requests can be handled by more than one printer.

If the *print-wheel* is `all`, the alerting defined in this command applies to all print wheels already defined to have an alert.

If the `-W` option is not given, the default procedure is that only one message will be sent per need to mount the print wheel. Not specifying the `-W` option is equivalent to

## lpadmin(1M)

specifying `-W` once or `-W 0`. If *minutes* is a number greater than zero, an alert will be sent at intervals specified by *minutes*.

If the `-Q` option is also given, the alert will be sent when a certain number (specified by the argument *requests*) of print requests that need the print wheel are waiting. If the `-Q` option is not given, or *requests* is 1 or any (which are both the default), a message is sent as soon as anyone submits a print request for the print wheel when it is not mounted.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

*System Administration Guide: Basic Administration*

<b>NAME</b>	lpfilter – administer filters used with the LP print service
<b>SYNOPSIS</b>	<code>/usr/sbin/lpfilter -f filter-name { -   -i   -l   -x   -F pathname }</code>
<b>DESCRIPTION</b>	The <code>lpfilter</code> command is used to add, change, delete, or list a filter used with the LP print service. These filters convert the content of a file to have a content type acceptable to a printer.
<b>OPTIONS</b>	<p>Arguments consist of the <code>-f filter-name</code> option and exactly one of the arguments appearing within braces ( { } ) in the SYNOPSIS.</p> <p><code>-</code> Adds or changes a filter as specified from standard input. The format of the input is specified below. If <code>-f all</code> is specified with the <code>-</code> option, the specified change is made to all existing filters. This is not useful.</p> <p><code>-f filter-name</code> Specifies the <i>filter-name</i> of the filter to be added, changed, reset, deleted, or listed. The filter name <code>all</code> is a special filter name defined below. The <code>-f</code> option is required.</p> <p><code>-F pathname</code> Adds or changes a filter as specified by the contents of the file <i>pathname</i>. The format of the file's contents is specified below. If <code>-f all</code> is specified with the <code>-F</code> option, the specified change is made to all existing filters. This is not useful.</p> <p><code>-i</code> Resets a filter to its default settings. Using <code>-f all</code> with the <code>-i</code> option restores all filters for which predefined settings are available to their original settings.</p> <p><code>-l</code> Lists a filter description. Using <code>-f all</code> with the <code>-l</code> option produces a list of all filters.</p> <p><code>-x</code> Deletes a filter. Using <code>-f all</code> with the <code>-x</code> option results in all filters being deleted.</p>
<b>Adding or Changing a Filter</b>	<p>The filter named in the <code>-f</code> option is added to the filter table. If the filter already exists, its description is changed to reflect the new information in the input.</p> <p>When <code>-</code> is specified, standard input supplies the filter description. When <code>-F</code> is specified, the file <i>pathname</i> supplies the filter description. One of these two options must be specified to add or change a filter.</p> <p>When an existing filter is changed with the <code>-F</code> or <code>-</code> option, lines in the filter description that are not specified in the new information are not changed. When a new filter is added with this command, unspecified lines receive default values. See below.</p> <p>Filters are used to convert the content of a request from its initial type into a type acceptable to a printer. For a given print request, the LP print service knows the following:</p> <ul style="list-style-type: none"> <li>■ The content type of the request (specified by <code>lp -T</code> or determined implicitly).</li> <li>■ The name of the printer (specified by <code>lp -d</code>).</li> </ul>

## lpfilter(1M)

- The printer type (specified by `lpadmin -T`).  
The printer type is intended to be a printer model, but some people specify it with a content type even though `lpadmin -I` is intended for this purpose.
- The content types acceptable to the printer (specified by `lpadmin -I`).  
The values specified by the `lpadmin -T` are treated as if they were specified by the `-I` option as well.
- The modes of printing asked for by the originator of the request (specified by various options to `lp`).

The system uses the above information to construct a list of one or more filters that converts the document's content type into a content type acceptable to the printer and consumes all `lp` arguments that invoke filters (`-Y` and `-P`).

The contents of the file (specified by the `-F` option) and the input stream from standard input (specified by `-`) must consist of a series of lines, such that each line conforms to the syntax specified by one of the seven lines below. All lists are comma or space separated. Each item contains a description.

Input types: *content-type-list*  
Output types: *content-type-list*  
Printer types: *printer-type-list*  
Printers: *printer-list*  
Filter type: *filter-type*  
Command: *shell-command*  
Options: *template-list*

Input types	This gives the content types that can be accepted by the filter. The default is any. The document content type must be a member of this list for the initial filter in the sequence.
Output types	This gives the content types that the filter can produce from any of the input (content) types. The default is any. The intersection of the output types of this list and the content types acceptable to the printer (from <code>lpadmin -I</code> and <code>lpadmin -T</code> ) must be non-null for the last filter in the sequence. For adjacent filters in the sequence, the intersection of output types of one and the input types of the next must be non-null.
Printer types	This gives the printer types for which this printer can be used. The LP print service will restrict the use of the filter to these printer types (from <code>lpadmin -T</code> ). The default is any.
Printers	This gives the names of the printers for which the filter can be used. The LP print service will restrict the use of the filter to just the printers named. The default is any.
Filter type	This marks the filter as a <code>slow</code> filter or a <code>fast</code> filter. Slow filters are generally those that take a long time to convert their input (that is, minutes or hours). They are run before the job is scheduled

	<p>for a printer, to keep the printers from being tied up while the filter is running. If a listed printer is on a remote system, the filter type for it must have the value <code>slow</code>. That is, if a client defines a filter, it must be a slow filter. Fast filters are generally those that convert their input quickly (that is, faster than the printer can process the data), or those that must be connected to the printer when run. Fast filters will be given to the interface program to run while connected to the physical printer.</p>
Command	<p>This specifies which program to run to invoke the filter. The full program pathname as well as fixed options must be included in the <i>shell-command</i>; additional options are constructed, based on the characteristics of each print request and on the <code>Options</code> field. A command must be given for each filter. The command must accept a data stream as standard input and produce the converted data stream on its standard output. This allows filter pipelines to be constructed to convert data not handled by a single filter.</p>
Options	<p>This is a comma-separated list of templates used by the LP print service to construct options to the filter from the characteristics of each print request listed in the table later. The <code>-y</code> and <code>-P</code> arguments to the <code>lp</code> command cause a filter sequence to be built even if there is no need for a conversion of content types.</p> <p>In general, each template is of the following form:</p> <p><i>keyword pattern = replacement</i></p> <p>The <i>keyword</i> names the characteristic that the template attempts to map into a filter-specific option; each valid <i>keyword</i> is listed in the table below.</p> <p>A <i>pattern</i> is one of the following: a literal pattern of one of the forms listed in the table, a single asterisk (*), or a regular expression. If <i>pattern</i> matches the value of the characteristic, the template fits and is used to generate a filter-specific option. The <i>replacement</i> is what will be used as the option.</p> <p>Regular expressions are the same as those found on the <code>regex(5)</code> manual page. This includes the <code>\(...\)</code> and <code>\n</code> constructions, which can be used to extract portions of the <i>pattern</i> for copying into the <i>replacement</i>, and the <code>&amp;</code>, which can be used to copy the entire <i>pattern</i> into the <i>replacement</i>.</p> <p>The <i>replacement</i> can also contain a <code>*</code>; it too, is replaced with the entire <i>pattern</i>, just like the <code>&amp;</code> of <code>regex(5)</code>.</p>
The keywords are:	

## lpfilter(1M)

lp Option	Characteristic	<i>keyword</i>	Possible <i>patterns</i>
-T	Content type (input)	INPUT	content-type
Not applicable	Content type (output)	OUTPUT	content-type
not applicable	Printer type	TERM	printer-type
-d	Printer name	PRINTER	<i>printer-name</i>
-f, -o cpi=	Character pitch	CPI	integer
-f, -o lpi=	Line pitch	LPI	integer
-f, -o length=	Page length	LENGTH	integer
-f, -o width=	Page width	WIDTH	integer
-P	Pages to print	PAGES	page-list
-S	Character set Print wheel	CHARSET CHARSET	character-set-name print-wheel-name
-f	Form name	FORM	form-name
-y	Modes	MODES	mode
-n	Number of copies	COPIES	<i>integer</i>
<b>Resetting a Filter to Defaults</b>	If the filter named is one originally delivered with the LP print service, the -i option restores the original filter description.		
<b>Deleting a Filter</b>	The -x option is used to delete the filter specified in filter-name from the LP filter table.		
<b>Listing a Filter Description</b>	The -l option is used to list the description of the filter named in filter-name. If the command is successful, the following message is sent to standard output:  Input types: <i>content-type-list</i> Output types: <i>content-type-list</i> Printer types: <i>printer-type-list</i> Printers: <i>printer-list</i> Filter type: <i>filter-type</i> Command: <i>shell-command</i> Options: <i>template-list</i>		

<b>Large File Behavior</b>	If the command fails, an error message is sent to standard error. See <code>largefile(5)</code> for the description of the behavior of <code>lpfilter</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Printing with the landscape option</p> <p>For example, the template</p> <pre>MODES landscape = -l</pre> <p>shows that if a print request is submitted with the <code>-y landscape</code> option, the filter will be given the option <code>-l</code>.</p> <p><b>EXAMPLE 2</b> Selecting the printer type</p> <p>As another example, the template</p> <pre>TERM * = -T *</pre> <p>shows that the filter will be given the option <code>-T printer-type</code> for whichever <i>printer-type</i> is associated with a print request using the filter.</p> <p><b>EXAMPLE 3</b> Using the keywords table</p> <p>Consider the template</p> <pre>MODES prwidth\=\(.*\) = -w\1</pre> <p>Suppose a user gives the command</p> <pre>lp -y prwidth=10</pre> <p>From the table above, the LP print service determines that the <code>-y</code> option is handled by a <code>MODES</code> template. The <code>MODES</code> template here works because the pattern <code>prwidth=</code> matches the <code>prwidth=10</code> given by the user. The replacement <code>-w1</code> causes the LP print service to generate the filter option <code>-w10</code>. If necessary, the LP print service will construct a filter pipeline by concatenating several filters to handle the user's file and all the print options. See <code>sh(1)</code> for a description of a pipeline. If the print service constructs a filter pipeline, the <code>INPUT</code> and <code>OUTPUT</code> values used for each filter in the pipeline are the types of input and output for that filter, not for the entire pipeline.</p>
<b>EXIT STATUS</b>	The following exit values are returned: 0 Successful completion. <i>non-zero</i> An error occurred.
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

**NOTES** If the `lp` command specifies more than one document, the filtering chain is determined by the first document. Other documents may have a different format, but they will print correctly only if the filter chain is able to handle their format.

<b>NAME</b>	lpforms – administer forms used with the LP print service
<b>SYNOPSIS</b>	<p><b>lpforms</b> -f <i>form-name</i> <i>option</i></p> <p><b>lpforms</b> -f <i>form-name</i> -A <i>alert-type</i> [-P <i>paper-name</i> [-d]] [-Q <i>requests</i>] [-W <i>minutes</i>]</p>
<b>DESCRIPTION</b>	<p>The <code>lpforms</code> command administers the use of preprinted forms, such as company letterhead paper, with the LP print service. A form is specified by its <i>form-name</i>. Users may specify a form when submitting a print request (see <code>lp(1)</code>). The argument <code>all</code> can be used instead of <i>form-name</i> with either of the command lines shown above. The first command line allows the administrator to add, change, and delete forms, to list the attributes of an existing form, and to allow and deny users access to particular forms. The second command line is used to establish the method by which the administrator is alerted that the form <i>form-name</i> must be mounted on a printer.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p>-f <i>form-name</i>      Specify a form.</p> <p>The first form of <code>lpforms</code> requires that one of the following <i>options</i> (<code>-</code>, <code>-l</code>, <code>-F</code>, <code>-x</code>) must be used:</p> <p>-F <i>pathname</i>      To add or change form <i>form-name</i>, as specified by the information in <i>pathname</i>.</p> <p>-                    To add or change form <i>form-name</i>, as specified by the information from standard input.</p> <p>-l                    To list the attributes of form <i>form-name</i>.</p> <p>-x                    To delete form <i>form-name</i> (this option must be used separately; it may not be used with any other option).</p> <p>The second form of the <code>lpforms</code> command requires the <code>-A <i>alert-type</i></code> option. The other options are optional.</p> <p>-A <i>alert-type</i>      Defines an alert to mount the form when there are queued jobs which need it.</p> <p>-P <i>paper-name</i> [-d]      Specify the paper name when creating the form. If <code>-d</code> is specified, this paper is the default.</p> <p>-Q <i>requests</i>              An alert will be sent when a certain number of print requests that need the form are waiting.</p> <p>-W <i>minutes</i>              An alert will be sent at intervals specified by minutes.</p>
<b>Adding or Changing a Form</b>	<p>The <code>-F <i>pathname</i></code> option is used to add a new form, <i>form-name</i>, to the LP print service, or to change the attributes of an existing form. The form description is taken from <i>pathname</i> if the <code>-F</code> option is given, or from the standard input if the <code>-</code> option is used. One of these two options must be used to define or change a form.</p>

## lpforms(1M)

*pathname* is the path name of a file that contains all or any subset of the following information about the form.

```
Page length: scaled-decimal-number1
Page width: scaled-decimal-number2
Number of pages: integer
Line pitch: scaled-decimal-number3
Character pitch: scaled-decimal-number4
Character set choice: character-set/print-wheel [mandatory]
Ribbon color: ribbon-color
Comment:
comment
Alignment pattern: [content-type]
content
```

The term “scaled-decimal-number” refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter attached to the number. Three types of scaled decimal numbers can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing *c*); numbers that show sizes in inches (marked with a trailing *i*); and numbers that show sizes in units appropriate to use (without a trailing letter); lines, characters, lines per inch, or characters per inch.

Except for the last two lines, the above lines may appear in any order. The *Comment* : and *comment* items must appear in consecutive order but may appear before the other items, and the *Alignment pattern*: and the *content* items must appear in consecutive order at the end of the file. Also, the *comment* item may not contain a line that begins with any of the key phrases above, unless the key phrase is preceded with a *>* sign. Any leading *>* sign found in the *comment* will be removed when the comment is displayed. There is no case distinction among the key phrases.

When this command is issued, the form specified by *form-name* is added to the list of forms. If the form already exists, its description is changed to reflect the new information. Once added, a form is available for use in a print request, except where access to the form has been restricted, as described under the *-u* option. A form may also be allowed to be used on certain printers only.

A description of each form attribute is below:

### Page length and Page Width

Before printing the content of a print request needing this form, the generic interface program provided with the LP print service will initialize the physical printer to handle pages *scaled-decimal-number1* long, and *scaled-decimal-number2* wide using the printer type as a key into the `terminfo(4)` database. The page length and page width will also be passed, if possible, to each filter used in a request needing this form.

### Number of pages

Each time the alignment pattern is printed, the LP print service will attempt to truncate the *content* to a single form by, if possible, passing to each filter the page subset of *1-integer*.

**Line pitch and Character pitch**

Before printing the content of a print request needing this form, the interface program provided with the LP print service will initialize the physical printer to handle these pitches, using the printer type as a key into the `terminfo(4)` database. Also, the pitches will be passed, if possible, to each filter used in a request needing this form. *scaled-decimal-number3* is in lines-per-centimeter if a `c` is appended, and lines-per-inch otherwise; similarly, *scaled-decimal-number4* is in characters-per-centimeter if a `c` is appended, and characters-per-inch otherwise. The character pitch can also be given as `elite` (12 characters-per-inch), `pica` (10 characters-per-inch), or `compressed` (as many characters-per-inch as possible).

**Character set choice**

When the LP print service alerts an administrator to mount this form, it will also mention that the print wheel *print-wheel* should be used on those printers that take print wheels. If printing with this form is to be done on a printer that has selectable or loadable character sets instead of print wheels, the interface programs provided with the LP print service will automatically select or load the correct character set. If `mandatory` is appended, a user is not allowed to select a different character set for use with the form; otherwise, the character set or print wheel named is a suggestion and a default only.

**Ribbon color**

When the LP print service alerts an administrator to mount this form, it will also mention that the color of the ribbon should be *ribbon-color*.

**Comment**

The LP print service will display the *comment* unaltered when a user asks about this form (see `lpstat(1)`).

**Alignment pattern**

When mounting this form, an administrator can ask for the *content* to be printed repeatedly, as an aid in correctly positioning the preprinted form. The optional *content-type* defines the type of printer for which *content* had been generated. If *content-type* is not given, `simple` is assumed. Note that the *content* is stored as given, and will be readable only by the user `lp`.

When an existing form is changed with this command, items missing in the new information are left as they were. When a new form is added with this command, missing items will get the following defaults:

```
Page Length: 66
Page Width: 80
Number of Pages: 1
Line Pitch: 6
Character Pitch: 10
Character Set Choice: any
Ribbon Color: any
```

**Deleting a Form**

LP print service" The `-x` option is used to delete the form *form-name* from the LP print service.

## lpforms(1M)

### Listing Form Attributes

The `-l` option is used to list the attributes of the existing form *form-name*. The attributes listed are those described under *Adding and Changing a Form*, above. Because of the potentially sensitive nature of the alignment pattern, only the administrator can examine the form with this command. Other people may use the `lpstat(1)` command to examine the non-sensitive part of the form description.

### Allowing and Denying Access to a Form

The `-u` option, followed by the argument `allow:login-ID-list` or `-u deny:login-ID-list` lets you determine which users will be allowed to specify a particular form with a print request. This option can be used with the `-F` or `-` option, each of which is described above under *Adding or Changing a Form*.

The *login-ID-list* argument may include any or all of the following constructs:

<i>login-ID</i>	A user on any system
<i>system_name!</i> <i>login-ID</i>	A user on system <i>system_name</i>
<i>system_name!</i> all	All users on system <i>system_name</i>
all! <i>login-ID</i>	A user on all systems
all	All users on all systems

The LP print service keeps two lists of users for each form: an “allow-list” of people allowed to use the form, and a “deny-list” of people that may not use the form. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users listed are added to the deny-list and removed from the allow-list. (Both forms of the `-u` option can be run together with the `-F` or the `-` option.)

If the allow-list is not empty, only the users in the list are allowed access to the form, regardless of the content of the deny-list. If the allow-list is empty but the deny-list is not, the users in the deny-list may not use the form, (but all others may use it). All users can be denied access to a form by specifying `-f deny:all`. All users can be allowed access to a form by specifying `-f allow:all`. (This is the default.)

### Setting an Alert to Mount a Form

The `-f form-name` option is used with the `-A alert-type` option to define an alert to mount the form when there are queued jobs which need it. If this option is not used to arrange alerting for a form, no alert will be sent for that form.

The method by which the alert is sent depends on the value of the *alert-type* argument specified with the `-A` option. The *alert-types* are:

mail	Send the alert message using the <code>mail</code> command to the administrator.
write	Write the message, using the <code>write</code> command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.
quiet	Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages

about a known problem. Once the form *form-name* has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the `-Q` option.

<code>showfault</code>	Attempt to execute a form alert handler on each system that has a print job for that form in the queue. The fault handler is <code>/etc/lp/alerts/form</code> . It is invoked with three parameters: <i>form_name</i> , <i>date</i> , <i>file_name</i> . <i>file_name</i> is the name of a file containing the form alert message.
<code>none</code>	Do not send messages until the <code>-A</code> option is given again with a different <i>alert-type</i> (other than <code>quiet</code> ).
<code>shell-command</code>	Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values <code>mail login-ID</code> and <code>write login-ID</code> respectively, where <i>login-ID</i> is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the <code>su</code> command to change to another login-ID. If the <code>su</code> command has been used to change the user ID, then the <i>user-name</i> for the new ID is used.
<code>list</code>	Display the type of the alert for the form on standard output. No change is made to the alert.

The message sent appears as follows:

```
The form form-name needs to be mounted
on the printer(s):printer (integer1 requests).
integer2 print requests await this form.
Use the ribbon-color ribbon.
Use the print-wheel print wheel, if appropriate.
```

The printers listed are those that the administrator has specified as candidates for this form. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the list of printers is the total number of requests awaiting the form. It will be less than the sum of the other numbers if some requests can be handled by more than one printer. The *ribbon-color* and *print-wheel* are those specified in the form description. The last line in the message is always sent, even if none of the printers listed use print wheels, because the administrator may choose to mount the form on a printer that does use a print wheel.

Where any color ribbon or any print wheel can be used, the statements above will read:

```
Use any ribbon.
Use any print-wheel.
```

## lpforms(1M)

If *form-name* is any, the *alert-type* defined in this command applies to any form for which an alert has not yet been defined. If *form-name* is `all`, the *alert-type* defined in this command applies to all forms.

If the `-W minutes` option is not given, the default procedure is that only one message will be sent per need to mount the form. Not specifying the `-W` option is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than 0, an alert will be sent at intervals specified by *minutes*.

If the `-Q requests` option is also given, the alert will be sent when a certain number (specified by the argument *requests*) of print requests that need the form are waiting. If the `-Q` option is not given, or the value of *requests* is 1 or any (which are both the default), a message is sent as soon as anyone submits a print request for the form when it is not mounted.

### Listing the Current Alert

The `-f` option, followed by the `-A` option and the argument *list* is used to list the *alert-type* that has been defined for the specified form *form-name*. No change is made to the alert. If *form-name* is recognized by the LP print service, one of the following lines is sent to the standard output, depending on the type of alert for the form.

- When *requests* requests are queued: alert with *shell-command* every *minutes* minutes
- When *requests* requests are queued: write to *user-name* every *minutes* minutes
- When *requests* requests are queued: mail to *user-name* every *minutes* minutes
- No alert

The phrase every *minutes* minutes is replaced with `once` if *minutes* (`-Wminutes`) is 0.

### Terminating an Active Alert

The `-A quiet` option is used to stop messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form has been mounted and then unmounted, messages will again be sent when the number of print requests reaches the threshold *requests*.

### Removing an Alert Definition

No messages will be sent after the `-A none` option is used until the `-A` option is given again with a different *alert-type*. This can be used to permanently stop further messages from being sent as any existing alert definition for the form will be removed.

### Large File Behavior

See `largefile(5)` for the description of the behavior of `lpforms` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

### EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

### FILES

`/etc/lp/alerts/form` Fault handler for `lpform`.

## lpget(1M)

<b>NAME</b>	lpget – get printing configuration
<b>SYNOPSIS</b>	<b>lpget</b> [-k <i>key</i> ] [ <i>destination...</i>   <i>list</i> ]
<b>DESCRIPTION</b>	<p>The <code>lpget</code> utility reads printing configuration information from the configuration databases in <code>\$HOME/.printers</code>, <code>/etc/printers.conf</code>, <code>printers.conf.byname</code>, <code>printers.org_dir</code>, and FNS printer contexts. This information, called a <i>configuration report</i>, is displayed to the standard output. See <code>printers(4)</code> and <code>printers.conf(4)</code> for information about the printer configuration databases.</p> <p><code>lpget</code> displays a configuration report for all keys for the specified destination or destinations by default. Use the <code>-k</code> option to display a configuration report for specific keys. Use the <code>list</code> operand to display a configuration report for all configured destinations.</p>
<b>OPTIONS</b>	<p>The following option is supported:</p> <p><code>-k <i>key</i></code>     Displays a configuration report for <i>key</i>. See <code>printers.conf(4)</code> for information about specifying <i>key</i>.</p>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>destination</i>     Displays a configuration report for <i>destination</i>. Destination can be either a printer or a class of printers, (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<code>../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information concerning POSIX.</p> <p><i>list</i>     Displays a configuration report for all configured destinations.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Displaying a Configuration Report for the <code>bsdaddr</code> Key</p> <p>The following example displays a configuration report for the <code>bsdaddr</code> key for printer <code>catalpa</code>.</p> <pre>example% lpget -k bsdaddr catalpa</pre> <p><b>EXAMPLE 2</b> A Configuration Report for all Keys for all Configured Destinations</p> <p>The following example displays a configuration report for all keys for all configured destinations.</p> <pre>example% lpget list</pre>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0                    Successful completion.</p>

non-zero           An error occurred.

**FILES**

`/etc/printers.conf`  
System printer configuration database.

`$HOME/.printers`  
User-configurable printer database.

`printers.conf.byname`  
NIS version of `/etc/printers.conf`.

`printers.org_dir`  
NIS+ version of `/etc/printers.conf`.

`fns.ctx_dir.domain`  
FNS version of `/etc/printers.conf`.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
Stability Level	Stable

**SEE ALSO**

`ldap(1)`, `lp(1)`, `lpc(1B)`, `lpq(1B)`, `lpr(1B)`, `lpstat(1)`, `lpadmin(1M)`, `lpset(1M)`, `printers(4)`, `printers.conf(4)`, `attributes(5)`, `standards(5)`

*System Administration Guide: Naming and Directory Services*

**NOTES**

Be mindful of the following if the LDAP database is used as the name service. If the `ldapclient(1M)` server is a replica LDAP server, LDAP printer database updates may not appear immediately, as the replica server may not have been updated by the master server and can be out of sync. For example, a printer that you deleted by using `lpset(1M)` may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. Refer to the *System Administration Guide: Naming and Directory Services* for more information on LDAP replication.

## lpmove(1M)

<b>NAME</b>	lpmove – move print requests								
<b>SYNOPSIS</b>	<b>lpmove</b> [ <i>request-ID</i> ] <i>destination</i> <b>lpmove</b> <i>destination1 destination2</i>								
<b>DESCRIPTION</b>	<p>The <b>lpmove</b> command moves print requests queued by <b>lp(1)</b> or <b>lpr(1B)</b> between destinations.</p> <p>The first form of <b>lpmove</b> moves specific print requests (<i>request-ID</i>) to a specific <i>destination</i>.</p> <p>The second form of the <b>lpmove</b> command moves all print requests from one destination (<i>destination1</i>) to another (<i>destination2</i>). This form of <b>lpmove</b> also rejects new print requests for <i>destination1</i>.</p> <p><b>lpmove</b> moves individual requests or entire queues only between local printers or between remote printers, not between a local and a remote printer. You can move only requests that were not previously transferred to the server.</p> <p>When moving requests, <b>lpmove</b> does not check the acceptance status of the destination to which the print requests are being moved (see <b>accept(1M)</b>). <b>lpmove</b> does not move requests that have options (for example, content type or requiring a special form) that cannot be handled by the new destination.</p>								
<b>OPERANDS</b>	<p>The following operands are supported:</p> <table><tr><td><i>request-ID</i></td><td>The specific print request to be moved. Specify <i>request-ID</i> as the identifier associated with a print request as reported by <b>lpstat</b>. See <b>lpstat(1)</b>.</td></tr><tr><td><i>destination</i></td><td>The name of the printer or class of printers (see <b>lpadmin(1M)</b>) to which <b>lpmove</b> moves a <i>specified</i> print request. Specify <i>destination</i> using atomic, POSIX-style (<i>server : destination</i>) syntax.</td></tr><tr><td><i>destination1</i></td><td>The name of the destination from which <b>lpmove</b> moves <i>all</i> print requests. Specify <i>destination</i> using atomic, POSIX-style (<i>server : destination</i>) syntax.</td></tr><tr><td><i>destination2</i></td><td>The name of the destination to which <b>lpmove</b> moves all print requests. Specify <i>destination</i> using atomic, POSIX-style (<i>server : destination</i>) syntax.</td></tr></table> <p>See <b>printers.conf(4)</b> for information regarding the naming conventions for atomic names and <b>standards(5)</b> for information regarding POSIX.</p>	<i>request-ID</i>	The specific print request to be moved. Specify <i>request-ID</i> as the identifier associated with a print request as reported by <b>lpstat</b> . See <b>lpstat(1)</b> .	<i>destination</i>	The name of the printer or class of printers (see <b>lpadmin(1M)</b> ) to which <b>lpmove</b> moves a <i>specified</i> print request. Specify <i>destination</i> using atomic, POSIX-style ( <i>server : destination</i> ) syntax.	<i>destination1</i>	The name of the destination from which <b>lpmove</b> moves <i>all</i> print requests. Specify <i>destination</i> using atomic, POSIX-style ( <i>server : destination</i> ) syntax.	<i>destination2</i>	The name of the destination to which <b>lpmove</b> moves all print requests. Specify <i>destination</i> using atomic, POSIX-style ( <i>server : destination</i> ) syntax.
<i>request-ID</i>	The specific print request to be moved. Specify <i>request-ID</i> as the identifier associated with a print request as reported by <b>lpstat</b> . See <b>lpstat(1)</b> .								
<i>destination</i>	The name of the printer or class of printers (see <b>lpadmin(1M)</b> ) to which <b>lpmove</b> moves a <i>specified</i> print request. Specify <i>destination</i> using atomic, POSIX-style ( <i>server : destination</i> ) syntax.								
<i>destination1</i>	The name of the destination from which <b>lpmove</b> moves <i>all</i> print requests. Specify <i>destination</i> using atomic, POSIX-style ( <i>server : destination</i> ) syntax.								
<i>destination2</i>	The name of the destination to which <b>lpmove</b> moves all print requests. Specify <i>destination</i> using atomic, POSIX-style ( <i>server : destination</i> ) syntax.								
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <table><tr><td>0</td><td>Successful completion.</td></tr><tr><td>non-zero</td><td>An error occurred.</td></tr></table>	0	Successful completion.	non-zero	An error occurred.				
0	Successful completion.								
non-zero	An error occurred.								
<b>FILES</b>	<table><tr><td>/var/spool/print/*</td><td>LP print queue.</td></tr></table>	/var/spool/print/*	LP print queue.						
/var/spool/print/*	LP print queue.

lpsched(1M)

<b>NAME</b>	lpsched – start the LP print service				
<b>SYNOPSIS</b>	<b>lpsched</b> [-f <i>num_filters</i> ] [-n <i>num_notifiers</i> ] [-p <i>fd_limit</i> ] [-r <i>reserved_fds</i> ]				
<b>DESCRIPTION</b>	<p>The lpsched command starts or restarts the LP print service.</p> <p>The lpshut command stops the LP print service. Printers that are restarted using lpsched reprint (in their entirety) print requests that were stopped by lpshut. See lpshut(1M).</p>				
<b>OPTIONS</b>	<p>The following options are supported:</p> <p>-f <i>num_filters</i>                      Specifies the number of concurrent slow filters that may be run on a print server. A default value of 1 is used if none is specified. Depending on server configuration, a value of 1 may cause printers to remain idle while there are jobs queued to them.</p> <p>-n <i>num_notifiers</i>                      Specifies the number of concurrent notification processes that can run on a print server. A default value of 1 is used when none is specified.</p> <p>-p <i>fd_limit</i>                              Specifies the file descriptor resource limit for the lpsched process. A default value of 4096 is used if none is specified. On extremely large and active print servers, it may be necessary to increase this value.</p> <p>-r <i>reserved_fds</i>                      Specifies the number of file descriptors that the scheduler reserves for internal communications under heavy load. A default value of 2 is used when none is specified. It should not be necessary to modify this value unless instructed to do so when troubleshooting problems under high load.</p>				
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0                                          Successful completion.</p> <p>non-zero                                  An error occurred.</p>				
<b>FILES</b>	/var/spool/lp/*                          LP print queue.

	<i>System Administration Guide: Basic Administration</i>				

<b>NAME</b>	lpset – set printing configuration in /etc/printers.conf or other supported databases
<b>SYNOPSIS</b>	<b>lpset</b> [-n system   nisplus   fns   ldap] [-x] [ [-D binddn] [-w passwd] [-h ldaphost]] [-a key=value] [-d key] destination
<b>DESCRIPTION</b>	<p>The lpset utility sets printing configuration information in the system configuration databases. Use lpset to create and update printing configuration in /etc/printers.conf, printers.org_dir (NIS+), or Federated Naming System (FNS). See nsswitch.conf(4), printers.conf(4), and fns(5).</p> <p>Only a superuser or a member of Group 14 may execute lpset.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><b>-n system nisplus fns ldap</b>  Create or update the configuration information for the <i>destination</i> entry in /etc/printers.conf, printers.org_dir (NIS+), LDAP or FNS printer contexts. <i>system</i> specifies that the information is created or updated in /etc/printers.conf. <i>nisplus</i> specifies that the information is created or updated in the printers.org_dir NIS+ table. <i>ldap</i> specifies that the information is written to an LDAP server. See NOTES. <i>fns</i> specifies that the information is written using federated naming context.</p> <p>If <b>-n</b> is not specified, <i>system</i> is the default.</p> <p><b>-x</b>  Remove all configuration for the <i>destination</i> entry from the database specified by the <b>-n</b> option.</p> <p><b>-a key=value</b>  Configure the specified <i>key=value</i> pair for the <i>destination</i>. See printers.conf(4) for information regarding the specification of <i>key=value</i> pairs.</p> <p><b>-d key</b>  Delete the configuration option specified by <i>key</i> for the <i>destination</i> entry. See printers.conf(4) for information regarding the specification of <i>key</i> and <i>key=value</i> pairs.</p> <p><b>-D binddn</b>  Use the distinguished name (DN) <i>binddn</i> to bind to the LDAP directory server.</p> <p><b>-w passwd</b>  Use <i>passwd</i> as the password for authentication to the LDAP directory server.</p> <p><b>-h ldaphost</b>  Specify an alternate host on which the LDAP server is running. This option is only used when <i>ldap</i> is specified as the naming service. If this option is not specified, the default is the current host system.</p>
<b>OPERANDS</b>	The following operand is supported:

## lpset(1M)

*destination* Specifies the entry in `/etc/printers.conf`, `printers.org_dir`, LDAP, or FNS, in which to create or modify information. *destination* names a printer of class of printers. See `lpadmin(1M)`. Each entry in `printers.conf` describes one destination. Specify *destination* using atomic or Federated Naming Service (FNS) (`../service/printer/..`) names. POSIX-style destination names are not acceptable. See `printers.conf(4)` for information regarding the naming conventions for atomic and FNS names and `standards(5)` for information regarding POSIX.

### EXAMPLES

#### EXAMPLE 1 Removing All Existing Printing Configuration Information

The following example removes all existing printing configuration information for destination `dogs` from `/etc/printers.conf`:

```
example% lpset -x dogs
```

#### EXAMPLE 2 Setting a key=value Pair

The following example sets the `user-equivalence=true` *key=value* pair for destination `tabloid` in FNS context:

```
example% lpset -n fns -a user-equivalence=true tabloid
```

#### EXAMPLE 3 Setting a key=value Pair in LDAP

```
example% lpset -n ldap -h ldap1.xyz.com -D "cn=Directory Manager" \
-w passwd -a key1=value1 printer1
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**FILES**

- `/etc/printers.conf`  
System configuration database.
- `printer.org_dir (NIS+)`  
NIS+ version of `/etc/printers.conf`.
- `fns.ctx_dir.domain`  
FNS version of `/etc/printers.conf`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Stability Level	Stable

**SEE ALSO** `ldap(1)`, `lp(1)`, `lpc(1B)`, `lpq(1B)`, `lpr(1B)`, `lpstat(1)`, `ldapclient(1M)`, `lpadmin(1M)`, `lpget(1M)`, `nsswitch.conf(4)`, `printers(4)`, `printers.conf(4)`, `attributes(5)`, `fns(5)`, `standards(5)`

*System Administration Guide: Naming and Directory Services*

**NOTES** If the `ldap` database is used, the printer administrator should be mindful of the following when updating printer information.

1. Because the domain information for the printer being updated is extracted from the `ldapclient(1M)` configuration, the LDAP server being updated must host the same domain that is used by the current `ldapclient(1M)` server.
2. If the LDAP server being updated is a replica LDAP server, the updates will be referred to the master LDAP server and completed there. The updates might be out of sync and not appear immediately, as the replica server may not have been updated by the master server. For example, a printer that you deleted by using `lpset` may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. See *System Administration Guide: Advanced Administration* for information on LDAP server replication.
3. Although users can use the LDAP command line utilities `ldapadd(1)` and `ldapmodify(1)` to update printer entries in the directory, the preferred method is to use `lpset`. Otherwise, if the `ldapadd` and `ldapmodify` utilities are used, the administrator must ensure that the `printer-name` attribute value is unique within the `ou=printers` container on the LDAP server. If the value is not unique, the result of modifications done using `lpset` or the Solaris Print Manager, `printmgr(1M)` may be unpredictable.

lpshut(1M)

**NAME** lpshut – stop the LP print service

**SYNOPSIS** **lpshut**

**DESCRIPTION** The lpshut command stops the LP print service.  
Printers that are printing when lpshut is invoked stop printing. Start or restart printers using lpsched(1M).

**EXIT STATUS** The following exit values are returned:  
0 Successful completion.  
non-zero An error occurred.

**FILES** /var/spool/lp/\* LP print queue.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsu

**SEE ALSO** lp(1), lpstat(1), lpadmin(1M), lpmove(1M), lpsched(1M), attributes(5)  
*System Administration Guide: Basic Administration*

<b>NAME</b>	lpsystem – register remote systems with the print service
<b>DESCRIPTION</b>	The <code>lpsystem</code> command is obsolete, and could be removed at any time. The print system no longer uses the information generated by <code>lpsystem</code> . See <code>lpadmin(1M)</code> , <code>lpusers(1M)</code> or <code>printers.conf(4)</code> for equivalent functionality.
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
Stability Level	Obsolete*

\* This command could be removed at any time.

**SEE ALSO** `lpadmin(1M)`, `lpusers(1M)`, `printers.conf(4)`, `attributes(5)`

## lpusers(1M)

<b>NAME</b>	lpusers – set printing queue priorities										
<b>SYNOPSIS</b>	<b>lpusers</b> -d <i>priority-level</i> <b>lpusers</b> -q <i>priority-level</i> -u <i>login-ID-list</i> <b>lpusers</b> -u <i>login-ID-list</i> <b>lpusers</b> -q <i>priority-level</i> <b>lpusers</b> -l										
<b>DESCRIPTION</b>	<p>The <b>lpusers</b> command sets limits to the queue priority level that can be assigned to jobs submitted by users of the LP print service.</p> <p>The first form of the command (with -d) sets the system-wide priority default to <i>priority-level</i>, where <i>priority-level</i> is a value of 0 to 39, with 0 being the highest priority. If a user does not specify a priority level with a print request (see <b>lp(1)</b>), the default priority level is used. Initially, the default priority level is 20.</p> <p>The second form of the command (with -q and -u) sets the default highest <i>priority-level</i> (0-39) that the users in <i>login-ID-list</i> can request when submitting a print request. The <i>login-ID-list</i> argument may include any or all of the following constructs:</p> <table><tr><td><i>login-ID</i></td><td>A user on any system</td></tr><tr><td><i>system_name</i>!<i>login-ID</i></td><td>A user on the system <i>system_name</i></td></tr><tr><td><i>system_name</i>!all</td><td>All users on system <i>system_name</i></td></tr><tr><td>all!<i>login-ID</i></td><td>A user on all systems</td></tr><tr><td>all</td><td>All users on all systems</td></tr></table> <p>Users that have been given a limit cannot submit a print request with a higher priority level than the one assigned, nor can they change a request that has already been submitted to have a higher priority. Any print requests submitted with priority levels higher than allowed will be given the highest priority allowed.</p> <p>The third form of the command (with -u) removes any explicit priority level for the specified users.</p> <p>The fourth form of the command (with -q) sets the default highest priority level for all users not explicitly covered by the use of the second form of this command.</p> <p>The last form of the command (with -l) lists the default priority level and the priority limits assigned to users.</p>	<i>login-ID</i>	A user on any system	<i>system_name</i> ! <i>login-ID</i>	A user on the system <i>system_name</i>	<i>system_name</i> !all	All users on system <i>system_name</i>	all! <i>login-ID</i>	A user on all systems	all	All users on all systems
<i>login-ID</i>	A user on any system										
<i>system_name</i> ! <i>login-ID</i>	A user on the system <i>system_name</i>										
<i>system_name</i> !all	All users on system <i>system_name</i>										
all! <i>login-ID</i>	A user on all systems										
all	All users on all systems										
<b>OPTIONS</b>	The following options are supported: -d <i>priority-level</i> Set the system-wide priority default to <i>priority-level</i> .										

- l  
List the default priority level and the priority limits assigned to users.
- q *priority-level*  
Set the default highest priority level for all users not explicitly covered.
- q *priority-level* -u *login-ID-list*  
Set the default highest *priority-level* that the users in *login-ID-list* can request when submitting a print request.
- u *login-ID-list*  
Remove any explicit priority level for the specified users.

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsu

**SEE ALSO** `lp(1)`, `attributes(5)`

lu(1M)

<b>NAME</b>	lu – FMLI-based interface to Live Upgrade functions																				
<b>SYNOPSIS</b>	<code>/usr/sbin/lu</code>																				
<b>DESCRIPTION</b>	<p>The <code>lu</code> program is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>lu</code> program is a Forms and Menu Language Interpreter-based user interface. (See <code>fml(1)</code> for a description of the Forms and Menu Language Interpreter.) <code>lu</code> enables you to create and upgrade boot environments (BEs) and perform other administrative tasks on BEs. The <code>lu</code> program performs a subset of the functions provided by the <code>lucreate(1M)</code> and <code>luupgrade(1M)</code> command-line utilities.</p> <p>The <code>lu</code> command accepts no arguments. After invoking <code>lu</code>, you receive a display with the following options:</p> <table><tr><td>Activate</td><td>Activate a boot environment. This option designates that the system boot from the specified BE upon next reboot. This option is equivalent to the command-line <code>luactivate(1M)</code> utility.</td></tr><tr><td>Cancel</td><td>Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and flash functions (all described below) at a later time. The cancel function enables you to cancel a scheduled job. This function is equivalent to the command-line <code>lucancel(1M)</code> utility.</td></tr><tr><td>Compare</td><td>Compare the contents of BEs. Enables you to obtain a detailed comparison of two BEs. Equivalent to the command-line <code>lucompare(1M)</code> utility.</td></tr><tr><td>Copy</td><td>Start/schedule a copy. Copies the contents of one BE to another. Equivalent of the command-line <code>lumake(1M)</code> utility. At any time, you can have only one Live Upgrade operation scheduled.</td></tr><tr><td>Create</td><td>Create a boot environment. Equivalent of the command-line <code>lucreate(1M)</code> utility.</td></tr><tr><td>Current</td><td>Display the name of the current boot environment. Equivalent of the command-line <code>lucurr(1M)</code> utility.</td></tr><tr><td>Delete</td><td>Delete a boot environment. Equivalent of the command-line <code>ludelete(1M)</code> utility.</td></tr><tr><td>List</td><td>List the file systems of a boot environment. Equivalent of the command-line <code>lufsl(1M)</code> utility.</td></tr><tr><td>Rename</td><td>Change the name of a boot environment. Equivalent of the command-line <code>lurename(1M)</code> utility.</td></tr><tr><td>Status</td><td>List the status of all boot environments. Equivalent of the command-line <code>lustatus(1M)</code> utility.</td></tr></table>	Activate	Activate a boot environment. This option designates that the system boot from the specified BE upon next reboot. This option is equivalent to the command-line <code>luactivate(1M)</code> utility.	Cancel	Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and flash functions (all described below) at a later time. The cancel function enables you to cancel a scheduled job. This function is equivalent to the command-line <code>lucancel(1M)</code> utility.	Compare	Compare the contents of BEs. Enables you to obtain a detailed comparison of two BEs. Equivalent to the command-line <code>lucompare(1M)</code> utility.	Copy	Start/schedule a copy. Copies the contents of one BE to another. Equivalent of the command-line <code>lumake(1M)</code> utility. At any time, you can have only one Live Upgrade operation scheduled.	Create	Create a boot environment. Equivalent of the command-line <code>lucreate(1M)</code> utility.	Current	Display the name of the current boot environment. Equivalent of the command-line <code>lucurr(1M)</code> utility.	Delete	Delete a boot environment. Equivalent of the command-line <code>ludelete(1M)</code> utility.	List	List the file systems of a boot environment. Equivalent of the command-line <code>lufsl(1M)</code> utility.	Rename	Change the name of a boot environment. Equivalent of the command-line <code>lurename(1M)</code> utility.	Status	List the status of all boot environments. Equivalent of the command-line <code>lustatus(1M)</code> utility.
Activate	Activate a boot environment. This option designates that the system boot from the specified BE upon next reboot. This option is equivalent to the command-line <code>luactivate(1M)</code> utility.																				
Cancel	Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and flash functions (all described below) at a later time. The cancel function enables you to cancel a scheduled job. This function is equivalent to the command-line <code>lucancel(1M)</code> utility.																				
Compare	Compare the contents of BEs. Enables you to obtain a detailed comparison of two BEs. Equivalent to the command-line <code>lucompare(1M)</code> utility.																				
Copy	Start/schedule a copy. Copies the contents of one BE to another. Equivalent of the command-line <code>lumake(1M)</code> utility. At any time, you can have only one Live Upgrade operation scheduled.																				
Create	Create a boot environment. Equivalent of the command-line <code>lucreate(1M)</code> utility.																				
Current	Display the name of the current boot environment. Equivalent of the command-line <code>lucurr(1M)</code> utility.																				
Delete	Delete a boot environment. Equivalent of the command-line <code>ludelete(1M)</code> utility.																				
List	List the file systems of a boot environment. Equivalent of the command-line <code>lufsl(1M)</code> utility.																				
Rename	Change the name of a boot environment. Equivalent of the command-line <code>lurename(1M)</code> utility.																				
Status	List the status of all boot environments. Equivalent of the command-line <code>lustatus(1M)</code> utility.																				

	Upgrade	Upgrade a boot environment or upgrade the OS on an inactive BE. This option enables you to upgrade to a new operating system or install new packages or patches on a specified BE. Equivalent of the command-line <code>luupgrade(1M)</code> utility.
	Flash	Flash a boot environment. This option enables you to install an operating system on a BE from a flash archive. You can perform the same function with <code>luupgrade(1M)</code> .
	Help	Displays help information. There are also context-specific help screens for many of the options.
	Exit	Exit <code>lu</code> .
<b>Navigation</b>		You navigate through <code>lu</code> 's various screens using arrow keys and function keys (usually F2 through F9 on the keyboard of a Sun desktop system). Available key functions are displayed at the base of the <code>lu</code> screen. You can use Ctrl-F, plus a number key, to duplicate a function key. For example, press Ctrl-F and the number key 2 to duplicate the F2 key.
		In a screen for a given option, you can press Esc to obtain context-specific help.
<b>Display Issues</b>		When viewing the FMLI interface remotely, such as over a <code>tip</code> line, you might need to set the <code>TERM</code> environment variable to <code>VT220</code> . When using the FMLI interface in a CDE environment use <code>dtterm</code> , rather than <code>xterm</code> , as the value of the <code>TERM</code> variable.
		The <code>lu</code> command supports only single-byte environments.
<b>Common Functions</b>		Most of the options listed above offer the following functions. These functions are accessible through function keys indicated at the base of the screen.
	Choice	Available to you whenever you have a field that can be filled in. Pressing the Choice function key gives you a popup screen displaying a list of alternatives. For example, for options involving copying or upgrading BEs, you receive a list of available BEs. You can then use arrow and function keys to make a selection from this popup. The choice function is useful because it prevents you from selecting an invalid alternative. In our example, it prevents you from choosing a BE that is not available for a copy or upgrade operation. Such non-availability might occur when a BE is in the midst of an upgrade.
	Cancel	Cancel an operation.
	Save	Proceed with an operation.
<b>Other Functions</b>		The "Create" option, described above, offers the following functions:
	Split	Split a file system. For example, you can split a <code>/</code> file system into <code>/</code> , <code>/usr</code> , and <code>/var</code> . To split a file system, you must have disk slices available on which to mount the separated file system(s). If you do not, <code>lu</code> invokes the <code>format(1M)</code> utility, in which you can use the <code>partition</code> option to create a new disk slice.

lu(1M)

**Merge** Join one or more file systems with its (or their) parent file system. For example, using a source BE that has separate `/`, `/usr`, and `/var` file systems, you can merge these file systems under `/` on a target BE.

**FILES** `/etc/lutab` list of BEs on the system

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

*Solaris Installation Guide*

<b>NAME</b>	luactivate – activate a boot environment
<b>SYNOPSIS</b>	<code>/usr/sbin/luactivate</code> [-l <i>error_log</i> ] [-o <i>outfile</i> ] [-s] [ <i>BE_name</i> ]
<b>DESCRIPTION</b>	<p>The <code>luactivate</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>luactivate</code> command, with no arguments, displays the name of the boot environment (BE) that will be active upon the next reboot of the system. When an argument (a BE) is specified, <code>luactivate</code> activates the specified BE.</p> <p><code>luactivate</code> activates a BE by making the BE's root partition bootable. On an IA machine, this might require that you take steps following the completion of <code>luactivate</code>. If so, <code>luactivate</code> displays the correct steps to take.</p> <p>To successfully activate a BE, that BE must meet the following conditions:</p> <ul style="list-style-type: none"> <li>■ The BE must have a status of "complete," as reported by <code>lustatus(1M)</code>.</li> <li>■ If the BE is not the current BE, you cannot have mounted the partitions of that BE (using <code>lumount(1M)</code> or <code>mount(1M)</code>).</li> <li>■ The BE you want to activate cannot be involved in an <code>lucompare(1M)</code> operation.</li> </ul> <p>After activating a specified BE, <code>luactivate</code> displays the steps to be taken for fallback in case of any problem on the next reboot. Make note of these instructions and follow them exactly, if necessary.</p> <p>The <code>luactivate</code> command requires root privileges.</p>
<b>OPTIONS</b>	<p>The <code>luactivate</code> command has the following options:</p> <p>-l <i>error_log</i>      Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p>-o <i>outfile</i>          All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p> <p>-s                    Forced synchronization. The first time you boot from a newly created BE, Live Upgrade software synchronizes this BE with the BE that was last active. (This is not necessarily the BE that was the source for the newly created BE.) It does not perform this synchronization after this initial boot, unless you use this option. Use this option with great caution, because you might not be aware or in control of changes that might have occurred in the last active BE.</p>
<b>OPERANDS</b>	<i>BE_name</i> Name of the BE to be activated.
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0                    Successful completion.</p> <p>&gt;0                  An error occurred.</p>

luactivate(1M)

## lucompare(1M)

<b>NAME</b>	lucompare – compare boot environments				
<b>SYNOPSIS</b>	<pre><b>/usr/sbin/lucompare</b> [-i <i>infile</i>   -t] [-o <i>outfile</i>] <i>BE_name</i> <b>/usr/sbin/lucompare</b> [-C <i>file</i> [-o <i>outfile</i>]]</pre>				
<b>DESCRIPTION</b>	<p>The <code>lucompare</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>lucompare</code> command compares the contents of the current boot environment (BE) with the contents of another BE. With the <code>-C</code> option, <code>lucompare</code> compares file statistics so that you can determine which files have changed on a BE since a specified time, such as the creation time of a BE. A specified BE must be inactive and in the complete state, as reported by the <code>lustatus(1M)</code> command. Also, a BE cannot have a copy job scheduled, which is also reported by <code>lustatus(1M)</code>. A specified BE cannot have any partitions mounted with <code>lumount(1M)</code> or <code>mount(1M)</code>.</p> <p>For each file system defined for a specified BE, <code>lucompare</code> compares all files with the files with the same pathnames in the current BE. The files present in the active BE, but not in the specified BE, and vice-versa, are reported. You also have the option to specify a list of files to be compared.</p> <p>If you specify the <code>-C</code> option, instead of doing an absolute comparison of the current BE with a target BE, <code>lucompare</code> compares the files in a specified BE with the list of files recorded in a file. When a BE is created, <code>lucreate(1M)</code> creates a file named <code>&lt;BE_name&gt;</code> in <code>/etc/lu/compare</code>. You can use the <code>-C</code> option to compare the files in a specified BE to this snapshot in <code>/etc/lu/compare</code> or you can compare the BE to a file previously created with the <code>-o</code> option. Comparing a BE to its own snapshot in <code>/etc/lu/compare</code> enables you to determine which files have changed on the BE since its creation.</p> <p>By default, the output of <code>lucompare</code> is written to stdout. With the <code>-C</code> option, you must use the <code>-o</code> option to specify an output file. The output for <code>lucompare</code> is a list of files that differ in permissions, owner, group, or sum, along with the reason for difference. The output format is shown below:</p> <pre>&gt; active BE &lt; BE_name reason &gt; file_name:owner:group:number_of_links:mode:type:size or major_minor number:checksum &lt; file_name:owner:group:number_of_links:mode:type:size or major_minor number:checksum</pre> <p>The above fields are obtained from the <code>stat(2)</code> structure of the file.</p> <p>The <code>type</code> field can be one of the following:</p> <table><tr><td>SYMLINK</td><td>symbolic link</td></tr><tr><td>FIFO</td><td>FIFO file</td></tr></table>	SYMLINK	symbolic link	FIFO	FIFO file
SYMLINK	symbolic link				
FIFO	FIFO file				

CHRSPC	character special
BLKSPC	block special
DIR	directory
REGFIL	regular file
UNKNOW	unknown file type

lucompare computes checksums only if the file on the specified BE matches its counterpart on the active BE in all of the fields described above. If the checksums differ, lucompare appends the differing checksums to the entries for the compared files.

The lucompare command requires root privileges.

**OPTIONS** The lucompare command has the following options:

<code>-C file</code>	Compare file statistics of BE with those recorded in <i>file</i> . <i>file</i> can be the snapshot created at BE creation time, <code>/etc/lu/compare/&lt;BE_name&gt;</code> , or a file previously created with the <code>-o</code> option. You must use the <code>-o</code> option with this option.
<code>-i infile</code>	Compare files listed in <i>infile</i> . The files to be compared should be an absolute filename. If the entry in the file is a directory, then comparison is recursive with respect to the directory. Mutually exclusive of <code>-t</code> .
<code>-o outfile</code>	Send output of differences to <i>outfile</i> . You must use this option if you use <code>-C</code> .
<code>-t</code>	Compare only nonbinary files. This is achieved by performing a <code>file(1)</code> command on each file in the tree walk and only comparing text files. Mutually exclusive of <code>-i</code> .

**OPERANDS** *BE\_name* Name of the BE to which the active BE will be compared. You cannot specify a BE that is involved in another Live Upgrade operation, or specify a BE for which you have mounted partitions (using `lumount(1M)` or `mount(1M)`).

**EXAMPLES** **EXAMPLE 1** Checking Differences Since BE Creation

The following command lists the differences in the BE `s8u5` between its creation time and the present.

```
lucompare -C /etc/lu/compare/:s8u5 -o /var/tmp/compare.out s8u5
```

Note that `/etc/lu/compare/:s8u5` is the file created by `lucreate` upon creation of a BE. The list of differences is sent to `/var/tmp/compare.out`.

## lucompare(1M)

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**FILES** /etc/lutab list of BEs on the system

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

**SEE ALSO** `lu(1M)`, `luactivate(1M)`, `lucancel(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `lufslst(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

**NOTES** The `lucompare` command makes no attempt to reconcile any differences it detects between BEs.

<b>NAME</b>	lucreate – create a new boot environment
<b>SYNOPSIS</b>	<pre><b>lucreate</b> [-c <i>BE_name</i>] [-C ( <i>boot_device</i>   - )] -n <i>BE_name</i> [-l <i>error_log</i>] [-o <i>outfile</i>] [-s ( -   <i>source_BE_name</i> )] [ [-M <i>slice_list</i>]   [-m <i>mountpoint:device:fs_type</i> [-m...]]]</pre>
<b>DESCRIPTION</b>	<p>The <code>lucreate</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature and its associated terminology.</p> <p>The <code>lucreate</code> command offers a set of command line options that enable you to perform the following functions:</p> <ul style="list-style-type: none"> <li>■ Create a new boot environment (BE), based on the current BE.</li> <li>■ Create a new BE, based on a BE other than the current BE.</li> <li>■ Join or separate the file systems of a BE onto a new BE. For example, join <code>/var</code> and <code>/opt</code> under <code>/</code>, or separate these directories to be mounted under different disk slices.</li> <li>■ Create the file systems for a BE, but leave those file systems unpopulated.</li> </ul> <p>You can perform the preceding functions using only <code>lucreate</code> command-line options or you can enter a set of options that will automatically invoke an FMLI-based interface that provides curses-based screens for Live Upgrade administration.</p> <p>The creation of a BE includes selecting the disk or device slices for all the mount points of the BE. You can also change the mount points of the BE using the <code>SPLIT</code> and <code>MERGE</code> functions of the FMLI-based configuration screen.</p> <p>Upon successful creation of a BE, you can use <code>lustatus(1M)</code> to view the state of that BE and <code>lufslst(1M)</code> to view the BE's file systems. You use <code>luupgrade(1M)</code> to upgrade the OS on that BE and <code>luactivate(1M)</code> to make a BE active, that is, designate it as the BE to boot from at the next reboot of the system.</p> <p>The <code>lucreate</code> command makes a distinction between the file systems that contain the OS—<code>/</code>, <code>/usr</code>, <code>/var</code>, and <code>/opt</code>—and those that do not, such as <code>/export</code>, <code>/home</code>, and other, user-defined file systems. The file systems in the first category cannot be shared between the source BE and the BE being created; they are always copied from the source BE to the target BE. By contrast, the user-defined file systems are shared by default. For Live Upgrade purposes, the file systems that contain the OS are referred to as non-shareable file systems; other file systems are referred to as shareable. A non-shareable file system listed in the source BE's <code>vfstab</code> is always copied to a new BE. For a shareable file system, if you specify a destination slice, the file system is copied. If you do not, the file system is shared.</p> <p>Except for a special use of the <code>-s</code> option, described below, you must have a source BE for the creation of a new BE. By default, it is the current BE. You can use the <code>-s</code> option to specify a BE other than the current BE.</p>

## lucreate(1M)

By default, all swap partitions on a source BE are shared between the source and target BE. You can use the `-m` option (see below) to specify a subset of swap partitions on a source BE for sharing with a target BE.

The `lucreate` command requires root privileges.

### OPTIONS

The `lucreate` command has the options listed below. Note that a BE name must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the “Quoting” section of `sh(1)`. The BE name can contain only single-byte, 8-bit characters.

Omission of `-m` or `-M` options (described below) in an `lucreate` command line invokes the FMLI-based interface, which allows you to select disk or device slices for a BE.

#### `-c BE_name`

Assigns the name `BE_name` to the current BE. This option is required only when the first BE is created. For the first time you run `lucreate`, if you omit `-c` you are prompted to name the current BE. If you use the `-c` option following the first BE creation, you receive an error message.

#### `-C (boot_device | -)`

Required when you have a mirrored root device on the source BE. Specifies the physical boot device the source BE is booted from. When you use `-` (hyphen) with the `-C` option, `lucreate` attempts to figure out the boot device. If you specify `boot_device`, you override this automatic lookup. When you specify `boot_device`, you are queried:

```
Is the physical device devname the boot device for
the logical device devname?
```

If you respond `y`, the command proceeds. With the `-C -`, the preceding query is suppressed. With either form of `-C`, if `lucreate` cannot find the boot device, you receive an error message. Use of the `-C -` form is a safe choice, because `lucreate` either finds the correct boot device or gives you the opportunity to specify that device in a subsequent command.

#### `-l error_log`

Error messages and other status messages are sent to `error_log`, in addition to where they are sent in your current environment.

#### `-m mountpoint:device:fs_type [-m mountpoint:device:fs_type] ...`

Specifies the `vfstab(4)` information for the new BE. The file systems specified as arguments to `-m` can be on the same disk or can be spread across multiple disks.

`mountpoint` can be any valid mount point or `-` (hyphen), indicating a swap partition. The `device` field can be one of the following:

- The name of a disk device, of the form `/dev/dsk/cnumtnumdnumsnm`.
- The keyword `merged`, indicating that the file system at the specified mount point is to be merged with its parent.

The *fs\_type* field can be *ufs*, indicating a UFS file system; *vxfs*, indicating a Veritas file system; or *swap*, indicating a swap file system.

At minimum, you must specify one disk or device slice, for root. You can do this with *-m*, *-M* (described below), or in the FMLI-based interface. You must specify an *-m* argument for each file system you want to create on a new BE. For example, if you have three file systems on a source BE (say, */*, */usr*, and */var*) and want these three entities as separate file systems on a new BE, you must specify three *-m* arguments. If you were to specify only one, in our example, */*, */usr*, and */var* would be merged on the new BE into a single file system, under */*.

When using the *-m* option to specify swap partition(s), you can designate only swap partitions (all or a subset) on the source BE. Any swap assignment made with *-m* replaces (that is, does not add to) existing swap assignments. See EXAMPLES, below.

**-M *slice\_list***

List of *-m* options, collected in the file *slice\_list*. Specify these arguments in the format specified for *-m*. Comment lines, beginning with a hash mark (#), are ignored. The *-M* option is useful where you have a long list of file systems for a BE. Note that you can combine *-m* and *-M* options. For example, you can store swap partitions in *slice\_list* and specify */* and */usr* slices with *-m*.

The *-m* and *-M* options support the listing of multiple slices for a given mount point. In processing these slices, *lucreate* skips any unavailable slices and selects the first available slice. See EXAMPLES.

**-n *BE\_name***

The name of the BE to be created. *BE\_name* must be unique on a given system.

**-o *outfile***

All command output is sent to *outfile*, in addition to where it is sent in your current environment.

**-s (*-* | *BE\_name*)**

Source for the creation of the new BE. This option enables you to use a BE other than the current BE as the source for creation of a new BE. If you specify a hyphen (-) as an argument to *-s*, *lucreate* creates the new BE, but does not populate it. You can then use *lumake(1M)* or *luupgrade(1M)* to populate the BE. This option is especially useful for installing a flash archive. See *flar(1M)*.

**EXAMPLES**

The *lucreate* command produces copious output. In the following examples, this output is not reproduced, except where it is needed for clarity.

**EXAMPLE 1** Creating a New Boot Environment for the First Time

The following command sequence creates a new boot environment on a machine on which a BE has never been created. Note that, in the first command, the *-c* option is omitted.

## lucreate(1M)

### EXAMPLE 1 Creating a New Boot Environment for the First Time (Continued)

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
lucreate: Please wait while your system configuration is determined.
lucreate: No name for Current BE.
lucreate: ERROR: The current BE is not named - please provide the name
to use for the current BE with the <-c> option.
```

The same command is entered, with the addition of `-c`:

```
lucreate -c first_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following creation of a BE, you use `luupgrade(1M)` to upgrade the OS on the new BE and `luactivate(1M)` to make that BE the BE you will boot from upon the next reboot of your machine. Note that the swap partition and all shareable file systems for `first_disk` will be available to (shared with) `second_disk`.

```
luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
many lines of output
luupgrade: Upgrade of Boot Environment <second_disk> successful.

luactivate second_disk
```

See `luupgrade(1M)` and `luactivate(1M)` for descriptions of those commands.

### EXAMPLE 2 Creating a BE using a Source Other than the Current BE

The following command uses the `-s` option to specify a source BE other than the current BE.

```
lucreate -s third_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

### EXAMPLE 3 Creating a BE from a Flash Archive

Performing this task involves use of `lucreate` with the `-s -` option and `luupgrade`.

```
lucreate -s - -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
brief messages
lucreate: Creation of Boot Environment <second_disk> successful.
```

With the `-s` option, the `lucreate` command completes its work within seconds. At this point, you can use `luupgrade` to install the flash archive:

```
luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \

```

**EXAMPLE 3** Creating a BE from a Flash Archive (Continued)

```
-J "archive_location http://example.com/myflash.flar"
```

See `luupgrade(1M)` for a description of that command.

**EXAMPLE 4** Using Swap Partitions on Multiple Disks

The command below creates a BE on a second disk and specifies the sharing of swap partitions on both the first and second disks. Note that the current boot environment must already be using `/dev/dsk/c0t0d0s1` and `/dev/dsk/c0t4d0s1` (on the second disk) as its swap partitions before entering this command.

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \
-m -:/dev/dsk/c0t0d0s1:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following completion of the preceding command, the BE `second_disk` will use both `/dev/dsk/c0t0d0s1` and `/dev/dsk/c0t4d0s1` as swap partitions. These swap assignments take effect only after booting from `second_disk`. If you have a long list of swap partitions, it is useful to use the `-M` option, as shown below.

**EXAMPLE 5** Using a Combination of `-m` and `-M` Options

In this example, a list of swap partitions is collected in the file `/etc/lu/swapslices`. The location and name of this file is user-defined. The contents of `/etc/lu/swapslices`:

```
-:/dev/dsk/c0t3d0s2:swap
-:/dev/dsk/c0t3d0s2:swap
-:/dev/dsk/c0t4d0s2:swap
-:/dev/dsk/c0t5d0s2:swap
-:/dev/dsk/c1t3d0s2:swap
-:/dev/dsk/c1t4d0s2:swap
-:/dev/dsk/c1t5d0s2:swap
```

This file is specified in the following command:

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-M /etc/lu/swapslices -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The BE `second_disk` will swap onto the partitions specified in `/etc/lu/swapslices`. As with the previous example, the current BE must already be using the swap partitions specified on the command line before you enter the `lucreate` command.

## lucreate(1M)

### EXAMPLE 6 Copying Versus Sharing

The following command copies the user file system `/home` (in addition to the non-shareable file systems `/` and `/usr`) from the current BE to the new BE:

```
lucreate /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-m /home:/dev/dsk/c0t4d0s4:ufs -n second_disk
```

The following command differs from the preceding in that the `-m` option specifying a destination for `/home` is omitted. The result of this is that `/home` will be shared between the current BE and the BE `second_disk`.

```
lucreate /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
```

### EXAMPLE 7 Invoking FMLI-based Interface

The command below, by omitting `-m` or `-M` options, invokes the FMLI-based interface for Live Upgrade operations. See `lu(1M)` for a description of this interface.

```
lucreate -n second_disk
```

The preceding command uses the current BE as the source for the target BE `second_disk`. In the FMLI interface, you can specify the target disk slices for `second_disk`. The following command is a variation on the preceding:

```
lucreate -n second_disk -s third_disk
```

In the preceding command, a source for the target BE is specified. As before, the FMLI interface comes up, enabling you to specify target disk slices for the new BE.

### EXAMPLE 8 Merging File Systems

The command below merges the `/usr/opt` file system into the `/usr` file system. First, here are the disk slices in the BE `first_disk`, expressed in the format used for arguments to the `-m` option:

```
:/dev/dsk/c0t4d0s0:ufs
/usr:/dev/dsk/c0t4d0s1:ufs
/usr/opt:/dev/dsk/c0t4d0s3:ufs
```

The following command creates a BE `second_disk` and performs the merge operation, merging `/usr/opt` with its parent, `/usr`.

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-m /usr/opt:merged:ufs -n second_disk
```

### EXAMPLE 9 Splitting a File System

Assume a source BE with `/`, `/usr`, and `/var` all mounted on the same disk slice. The following command creates a BE `second_disk` that has `/`, `/usr`, and `/var` all mounted on different disk slices.

**EXAMPLE 9** Splitting a File System *(Continued)*

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
/var:/dev/dsk/c0t4d0s3:ufs -n second_disk
```

This separation of a file system's (such as root's) components onto different disk slices is referred to as splitting a file system.

**EXAMPLE 10** Specifying Alternative Slices

The following command uses multiple `-m` options as alternative disk slices for the new BE `second_disk`.

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /:/dev/dsk/c0t4d0s1:ufs \
-m /:/dev/dsk/c0t4d0s5:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The preceding command specifies three possible disk slices, `s0`, `s1`, and `s5` for the `/` file system. `lucreate` selects the first one of these slices that is not being used by another BE. Note that the `-s` option is omitted, meaning that the current BE is the source BE for the creation of the new BE.

**EXIT STATUS** The following exit values are returned:

0           Successful completion.  
>0          An error occurred.

**FILES** `/etc/lutab` list of BEs on the system

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

**SEE ALSO** `lu(1M)`, `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucurr(1M)`, `ludelete(1M)`, `lufslis(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

**NOTES** When splitting a directory into multiple mount points, hard links are not maintained across file systems. For example, if `/usr/test1/buglist` is hard linked to `/usr/test2/buglist`, and `/usr/test1` and `/usr/test2` are split into separate file systems, the link between the files will no longer exist. `lucreate` issues a warning message to that effect and a symbolic link is created to replace the lost hard link.

## lucreate(1M)

lucreate cannot prevent you from making invalid configurations with respect to non-shareable file systems. For example, you could enter an `lucreate` command that would create separate file systems for `/` and `/kernel`—an invalid division of `/`. When creating file systems for a boot environment, the rules are identical to the rules for creating file systems for the Solaris operating environment.

<b>NAME</b>	lucurr – display the name of the active boot environment				
<b>SYNOPSIS</b>	<code>/usr/sbin/lucurr [-l <i>error_log</i>] [-m <i>mount_point</i>] [-o <i>outfile</i>]</code>				
<b>DESCRIPTION</b>	<p>The <code>lucurr</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>lucurr</code> command displays the name of the currently running boot environment (BE). If no BEs are configured on the system, <code>lucurr</code> displays the message "No Boot Environments are defined". Note that <code>lucurr</code> reports only the name of the current BE, not the BE that will be active upon the next reboot. Use <code>lustatus(1M)</code> for this information.</p> <p>The <code>lucurr</code> command requires root privileges.</p>				
<b>OPTIONS</b>	<p>The <code>lucurr</code> command has the following options:</p> <p><code>-l <i>error_log</i></code>      Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p><code>-m <i>mount_point</i></code>    Returns the name of the BE that owns <i>mount_point</i>. This can be a mount point of the current BE or the mount point of a BE other than the current BE. If the latter, the file system of the BE must have been mounted with <code>lumount(1M)</code> or <code>mount(1M)</code> before entering this option.</p> <p><code>-o <i>outfile</i></code>        All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p>				
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0            Successful completion.</p> <p>&gt;0         An error occurred.</p>				
<b>FILES</b>	<code>/etc/lutab</code> list of BEs on the system				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWluu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWluu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWluu				
<b>SEE ALSO</b>	<code>lu(1M)</code> , <code>luactivate(1M)</code> , <code>lucancel(1M)</code> , <code>lucompare(1M)</code> , <code>lucreate(1M)</code> , <code>ludelete(1M)</code> , <code>lufsls(1M)</code> , <code>lumake(1M)</code> , <code>lumount(1M)</code> , <code>lurename(1M)</code> , <code>lustatus(1M)</code> , <code>luupgrade(1M)</code> , <code>lutab(4)</code> , <code>attributes(5)</code> , <code>live_upgrade(5)</code>				

## ludelete(1M)

<b>NAME</b>	ludelete – delete a boot environment				
<b>SYNOPSIS</b>	<b>ludelete</b> [-l <i>error_log</i> ] [-o <i>outfile</i> ] <i>BE_name</i>				
<b>DESCRIPTION</b>	<p>The <code>ludelete</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>ludelete</code> command deletes all records associated with a boot environment (BE) from <code>/etc/lutab</code> (see <code>lutab(4)</code>) on all defined complete BEs. A complete BE is one that is not participating in an <code>lucreate(1M)</code>, <code>luupgrade(1M)</code>, or <code>lucompare(1M)</code> operation. Use <code>lustatus(1M)</code> to determine a BE's status. You can delete neither the active BE, nor the BE that is activated upon the next reboot. Also, you cannot upgrade a BE that has file systems mounted with <code>lumount(1M)</code> or <code>mount(1M)</code>.</p>				
<b>OPTIONS</b>	<p>The <code>ludelete</code> command has the following options:</p> <p>-l <i>error_log</i>      Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p>-o <i>outfile</i>        All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p>				
<b>OPERANDS</b>	<i>BE_name</i> Name of the BE to be deleted.				
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0                  Successful completion.</p> <p>&gt;0                An error occurred.</p>				
<b>FILES</b>	<code>/etc/lutab</code> list of BEs on the system

- NAME** lufslis – list configuration of a boot environment
- SYNOPSIS** **lufslis** [-l *error\_log*] [-o *outfile*] *BE\_name*
- DESCRIPTION** The **lufslis** command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See **live\_upgrade(5)** for a description of the Live Upgrade feature.
- The **lufslis** command lists the configuration of a boot environment (BE). The output contains the disk slice (file system), file system type, and file system size for each BE mount point.
- The following is an example of **lufslis** output.
- ```
# lufslis BE_name
Filesystem                fstype          size(Mb) Mounted on
-----
/dev/dsk/c0t0d0s1         swap            512.11  -
/dev/dsk/c0t4d0s3         ufs             3738.29  /
/dev/dsk/c0t4d0s4         ufs             510.24  /opt
```
- File system type can be **ufs**, **swap**, or **vxfs**, for a Veritas file system. Under the **Filesystem** heading can be a disk slice or a logical device, such as a disk metadvice used by volume management software.
- The **lufslis** command requires root privileges.
- OPTIONS** The **lufslis** command has the following options:
- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
 - o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- OPERANDS** *BE_name* Name of the BE for which file systems are to be reported. You cannot specify a BE that is involved in another Live Upgrade operation.
- EXIT STATUS** The following exit values are returned:
- 0 Successful completion.
 - >0 An error occurred.
- FILES** /etc/lutab list of BEs on the system
- ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| NAME | lumake – populate a boot environment | | | | | | | | | | | | |
| SYNOPSIS | <p>lumake [-l <i>error_log</i>] -t <i>time</i> [-o <i>outfile</i>] [-s <i>source_BE</i>] -n <i>BE_name</i> [-m <i>email_address</i>]</p> <p>lumake [-l <i>error_log</i>] [-o <i>outfile</i>] [-s <i>source_BE</i>] -n <i>BE_name</i></p> | | | | | | | | | | | | |
| DESCRIPTION | <p>The lumake command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The lumake command populates (that is, copies files to) the file systems of a specified boot environment (BE) by copying files from the corresponding file systems of the active or a source (-s) BE. Any existing data on the target BE are destroyed. All file systems on the target BE are re-created.</p> <p>The target BE must already exist. Use <code>lucreate(1M)</code> to create a new BE.</p> <p>The lumake command requires root privileges.</p> | | | | | | | | | | | | |
| OPTIONS | <p>The lucompare command has the following options:</p> <table border="0"> <tr> <td style="vertical-align: top;">-t <i>time</i></td> <td>Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the <code>at(1)</code> man page. At any time, you can have only one Live Upgrade operation scheduled. You can use <code>lucancel(1M)</code> to cancel a scheduled lumake operation.</td> </tr> <tr> <td style="vertical-align: top;">-l <i>error_log</i></td> <td>Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</td> </tr> <tr> <td style="vertical-align: top;">-o <i>outfile</i></td> <td>All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</td> </tr> <tr> <td style="vertical-align: top;">-m <i>email_address</i></td> <td>Allows you to email lumake output to a specified address upon command completion. There is no checking of <i>email_address</i>. You can use this option only in conjunction with -t.</td> </tr> <tr> <td style="vertical-align: top;">-n <i>BE_name</i></td> <td>Name of the BE to be populated.</td> </tr> <tr> <td style="vertical-align: top;">-s <i>source_BE</i></td> <td>The optional name of a source BE. If you omit this option, lumake uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use <code>lustatus(1M)</code> to determine a BE's status.</td> </tr> </table> | -t <i>time</i> | Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the <code>at(1)</code> man page. At any time, you can have only one Live Upgrade operation scheduled. You can use <code>lucancel(1M)</code> to cancel a scheduled lumake operation. | -l <i>error_log</i> | Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment. | -o <i>outfile</i> | All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment. | -m <i>email_address</i> | Allows you to email lumake output to a specified address upon command completion. There is no checking of <i>email_address</i> . You can use this option only in conjunction with -t. | -n <i>BE_name</i> | Name of the BE to be populated. | -s <i>source_BE</i> | The optional name of a source BE. If you omit this option, lumake uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use <code>lustatus(1M)</code> to determine a BE's status. |
| -t <i>time</i> | Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the <code>at(1)</code> man page. At any time, you can have only one Live Upgrade operation scheduled. You can use <code>lucancel(1M)</code> to cancel a scheduled lumake operation. | | | | | | | | | | | | |
| -l <i>error_log</i> | Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment. | | | | | | | | | | | | |
| -o <i>outfile</i> | All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment. | | | | | | | | | | | | |
| -m <i>email_address</i> | Allows you to email lumake output to a specified address upon command completion. There is no checking of <i>email_address</i> . You can use this option only in conjunction with -t. | | | | | | | | | | | | |
| -n <i>BE_name</i> | Name of the BE to be populated. | | | | | | | | | | | | |
| -s <i>source_BE</i> | The optional name of a source BE. If you omit this option, lumake uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use <code>lustatus(1M)</code> to determine a BE's status. | | | | | | | | | | | | |
| EXIT STATUS | <p>The following exit values are returned:</p> <table border="0"> <tr> <td style="vertical-align: top;">0</td> <td>Successful completion.</td> </tr> <tr> <td style="vertical-align: top;">>0</td> <td>An error occurred.</td> </tr> </table> | 0 | Successful completion. | >0 | An error occurred. | | | | | | | | |
| 0 | Successful completion. | | | | | | | | | | | | |
| >0 | An error occurred. | | | | | | | | | | | | |

| | | | | | |
|--------------------|--|----------------|--|--------------------|--|
| NAME | lumount, luumount – mount or unmount all file systems in a boot environment | | | | |
| SYNOPSIS | <pre>lumount [-l error_log] [-o outfile] BE_name [mount_point] luumount [-l error_log] [-o outfile] BE_name</pre> | | | | |
| DESCRIPTION | <p>The lumount and luumount commands are part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The lumount and luumount commands enable you to mount or unmount all of the filesystems in a boot environment (BE). This allows you to inspect or modify the files in a BE while that BE is not active. By default, lumount mounts the file systems on a mount point of the form <code>/.alt.<num></code>, where <code><num></code> is a random number.</p> <p>The lumount and luumount commands require root privileges.</p> | | | | |
| OPTIONS | <p>The lumount and luumount commands have the following options:</p> <ul style="list-style-type: none"> <code>-l error_log</code>
Error and status messages are sent to <code>error_log</code>, in addition to where they are sent in your current environment. <code>-o outfile</code>
All command output is sent to <code>outfile</code>, in addition to where it is sent in your current environment. | | | | |
| OPERANDS | <table border="0"> <tr> <td style="vertical-align: top;"><i>BE_name</i></td> <td>Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an lumount or luumount command, the status of a BE must be complete, as reported by <code>lustatus(1M)</code>. Also, none of the BE's disk slices can be mounted (through use of <code>mount(1M)</code>).</td> </tr> <tr> <td style="vertical-align: top;"><i>mount_point</i></td> <td>For lumount only, a mount point to use instead of the default <code>/.alt.<num></code>. If <code>mount_point</code> does not exist, lumount creates it.</td> </tr> </table> | <i>BE_name</i> | Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an lumount or luumount command, the status of a BE must be complete, as reported by <code>lustatus(1M)</code> . Also, none of the BE's disk slices can be mounted (through use of <code>mount(1M)</code>). | <i>mount_point</i> | For lumount only, a mount point to use instead of the default <code>/.alt.<num></code> . If <code>mount_point</code> does not exist, lumount creates it. |
| <i>BE_name</i> | Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an lumount or luumount command, the status of a BE must be complete, as reported by <code>lustatus(1M)</code> . Also, none of the BE's disk slices can be mounted (through use of <code>mount(1M)</code>). | | | | |
| <i>mount_point</i> | For lumount only, a mount point to use instead of the default <code>/.alt.<num></code> . If <code>mount_point</code> does not exist, lumount creates it. | | | | |
| EXAMPLES | <p>EXAMPLE 1 Specifying a Mount Point</p> <p>The following command creates the mount point <code>/test</code> and mounts the file systems of the BE <code>second_disk</code> on <code>/test</code>.</p> <pre># lumount second_disk /test /test</pre> <p>You can then <code>cd</code> to <code>/test</code> to view the file systems of <code>second_disk</code>.</p> | | | | |

lumount(1M)

EXAMPLE 2 Unmounting File Systems

The following command unmounts the file systems of the BE `second_disk`. In this example, we `cd` to `/` to ensure we are not in any of the file systems in `second_disk`.

```
# cd /
# luumount second_disk
#
```

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred.

- NAME** lurename – change the name of a boot environment
- SYNOPSIS** **lurename** -e *BE_name* -n *new_name* [-l *error_log*] [-o *outfile*]
- DESCRIPTION** The lurename command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.
- The lurename command renames the boot environment (BE) *BE_name* to *new_name*.
- The string *new_name* must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the “Quoting” section of `sh(1)`. The BE name can contain only single-byte, 8-bit characters. Also, *new_name* must be unique on the system.
- A BE must have the status “complete” before you rename it. Use `lustatus(1M)` to determine a BE’s status. Also, you cannot rename a BE that has file systems mounted with `lumount(1M)` or `mount(1M)`.
- Renaming a BE is often useful when you upgrade the BE from one Solaris release to another. For example, following an operating system upgrade, you might rename the BE `solaris7` to `solaris8`.
- The lurename command requires root privileges.
- OPTIONS** The lurename command has the options listed below.
- e *BE_name* Name of the BE whose name you want to change.
 - l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
 - n *new_name* New name of the BE. *new_name* must be unique on a given system.
 - o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- EXIT STATUS** The following exit values are returned:
- 0 Successful completion.
 - >0 An error occurred.
- FILES** /etc/lutab list of BEs on the system

| disk_b_S8 | no | no | no | - | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| OPTIONS | <p>The <code>lustatus</code> command has the following options:</p> <table border="0"> <tr> <td style="padding-right: 20px;">-l <i>error_log</i></td> <td>Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</td> </tr> <tr> <td>-o <i>outfile</i></td> <td>All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</td> </tr> </table> | -l <i>error_log</i> | Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment. | -o <i>outfile</i> | All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment. | | | | | | | | | | | | | | | | | | | | | | | | | | |
| -l <i>error_log</i> | Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| -o <i>outfile</i> | All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

lustatus(1M)

OPERANDS *BE_name* Name of the BE for which to obtain status. If *BE_name* is omitted, `lustatus` displays status for all BEs in the system.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES `/etc/lutab` list of BEs on the system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

|--|---|
| NAME | luupgrade – installs, upgrades, and performs other functions on software on a boot environment |
| SYNOPSIS | luupgrade [-iIufpPtTcC] [<i>options</i>] |
| DESCRIPTION | <p>The <code>luupgrade</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>luupgrade</code> command enables you to install software on a specified boot environment (BE). Specifically, <code>luupgrade</code> performs the following functions:</p> <ul style="list-style-type: none"> ■ Upgrades an operating system image on a BE (-u option). The source for the image can be any valid Solaris installation medium. ■ Run an installer program to install software from an installation medium (-i option). ■ Extract a flash archive onto a BE (-f option). (See <code>flar(1M)</code>.) ■ Add a package to (-p) or remove a package from (-P) a BE. ■ Add a patch to (-t) or remove a patch from (-T) a BE. ■ Check (-c) or obtain information about (-I) packages. ■ Check an operating system installation medium (-c). <p>Before using <code>luupgrade</code>, you must have created a BE, using either the <code>lucreate(1M)</code> command or <code>lu(1M)</code>, the FMLI-based user interface. You can upgrade only BEs other than the current BE.</p> <p>The functions described in the preceding list each has its own set of options, which are described separately for each function.</p> <p>Note that, for successful completion of an <code>luupgrade</code> operation, the status of a BE must be complete, as reported by <code>lustatus(1M)</code>. Also, the BE must not have any mounted disk slices, mounted either with <code>lumount(1M)</code> or <code>mount(1M)</code>.</p> <p>The <code>luupgrade</code> command requires root privileges.</p> |
| Options that Apply to All Uses | <p>The following options are available for all uses of <code>luupgrade</code>:</p> <p>-l <i>error_log</i> Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p>-o <i>outfile</i> All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p> <p>-N Dry-run mode. Enables you to determine whether your command arguments are correctly formed. Does not apply to the -c (check medium) function.</p> |
| Upgrading an Operating System Image | The syntax for this use of <code>luupgrade</code> is as follows: |

luupgrade(1M)

```
luupgrade -u -n BE_name -s os_image_path [ -j profile_path ]  
[ -l error_log ] [ -o outfile ] [-N]
```

The first option, `-u`, indicates the function to perform—to install an OS image. The remaining options, shown above, are described as follows:

`-n BE_name` Name of the BE to receive an OS upgrade.

`-s os_image_path` Path name of a directory containing an OS image. This can be a directory on an installation medium such as a CD-ROM or can be an NFS or UFS directory.

`-j profile_path` Path to a JumpStart profile. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software.

Note that if you are upgrading from a medium with multiple components, such as from multiple CDs, use `luupgrade` with the `-i` option, as described in the section below, to install software from the second and any following media.

Running an Installer Program

The syntax for this use of `luupgrade` is as follows:

```
luupgrade -i -n BE_name -s installation_medium [ -N ]  
[ -O "installer_options" ] [ -l error_log ] [ -o outfile ]
```

The first option, `-i`, indicates the function to perform—to run an installer program on the installation specified with `-s`. The remaining options, shown above, are described as follows:

`-n BE_name` Name of the BE on which software is to be installed.

`-O "installer_options"` Options passed directly to the Solaris installer program. See `installer(1M)` for descriptions of the installer options.

`-s installation_medium` Path name of an installation medium. This can be a CD, or an NFS or UFS directory.

With the `-i` option, `luupgrade` looks for an installation program on the specified medium and runs that program.

The `-i` option has a special use when you use the `-u` option, described above, to install software from a multiple-component medium, such as multiple CDs. See EXAMPLES.

Upgrading from a Flash Archive

The syntax for this use of `luupgrade` is as follows:

```
luupgrade -f -n BE_name -s os_image_path ( -a archive | -j profile_path  
| -J "profile" ) [ -l error_log ] [ -o outfile ] [ -N ]
```

The first option, `-f`, indicates the function to perform—to upgrade an OS from a flash archive. The remaining options, shown above, are described as follows:

`-n BE_name`
Name of the BE to receive an OS installation.

- s *os_image_path*
Path name of a directory containing an OS image. This can be a directory on an installation medium, such as a CD-ROM, or can be an NFS or UFS directory.
- a *archive*
Path to the flash archive when the archive is available on the local file system. You must specify one of -a, -j , or -J .
- j *profile_path*
Path to a JumpStart profile that is configured for a flash installation. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software. You must specify one of -a, -j , or -J .
- J "*profile*"
Entry from a JumpStart profile that is configured for a flash installation. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software. You must specify one of -a, -j , or -J .

Add or Remove Packages

The `luupgrade` command uses `-p` to add a package and `-P` to remove a package. The syntax is as follows:

For adding packages:

```
luupgrade -p -n BE_name -s packages_path [ -l error_log ][ -o outfile ]
[ -O "pkgadd_options" ] [ -a admin ] [ pkginst [ pkginst... ] ] [ -N ]
```

For removing packages:

```
luupgrade -P -n BE_name [ -l error_log ][ -o outfile ]
[ -O "pkgrm_options" ] [ pkginst [ pkginst... ] ] [ -N ]
```

The first option, `-p`, to add packages, or `-P` to remove packages, indicates the function to perform. The remaining options, shown above, are described as follows:

- n *BE_name*
Name of the BE to which packages will be added or from which packages will be removed.
- s *packages_path*
(For adding packages only.) Path name of a directory containing packages to add. You can substitute `-d` for `-s` . The `-d` support is for `pkgadd(1M)` compatibility.
- d *packages_path*
Identical to `-s`. Use of `-s` is recommended.
- O "*pkgadd_options*" or "*pkgrm_options*"
Options passed directly to `pkgadd` (for `-p`) or `pkgrm` (for `-P`). See `pkgadd(1M)` and `pkgrm(1M)` for descriptions of the options for those commands.
- a *admin*
(For adding packages only.) Path to an admin file. Identical to the `pkgadd -a` option. Use of the `-a` option here is identical to `-O " -a admin"`

luupgrade(1M)

Add or Remove Patches

pkginst [*pkginst...*]

Zero or more packages to add or remove. For adding packages, the default is to add all of the packages specified with the `-s` option, above. Separate multiple package names with spaces.

The `luupgrade` command uses `-t` to add a patch and `-T` to remove a patch. The syntax is as follows:

For adding patches:

```
luupgrade -t -n BE_name -s patch_path [ -l error_log ][ -o outfile ]
[ -O "patchadd_options" ] [ patch_name [ patch_name... ] ] [ -N ]
```

For removing patches:

```
luupgrade -T -n BE_name [ -l error_log ][ -o outfile ]
[ -O "patchrm_options" ] [ patch_name [ patch_name... ] ] [ -N ]
```

The first option, `-t`, to add patches, or `-T` to remove patches, indicates the function to perform. The remaining options, shown above, are described as follows:

`-n BE_name`

Name of the BE to which patches will be added or from which patches will be removed.

`-s patch_path`

(For adding patches only.) Path name of a directory containing patches to add.

`-O "patchadd_options" or "patchrm_options"`

Options passed directly to `patchadd` (for `-p`) or `patchrm` (for `-P`). See `patchadd(1M)` or `patchrm(1M)` for a description of these options.

patch_name [*patch_name...*]

Zero or more patches to add or remove. For adding patches, the default is to add all of the patches specified with the `-s` option, above. Separate multiple patch names with spaces.

Check or Return Information on Packages

Use the `-C` to perform a `pkgchk(1M)` on all or the specified packages on a BE. Use the `-I` option to perform a `pkginfo(1)`.

For performing a `pkgchk`:

```
luupgrade -C -n BE_name [ -l error_log ][ -o outfile ]
[ -O "pkgchk_options" ][ pkginst [ pkginst... ] ] [ -N ]
```

For performing a `pkginfo`:

```
luupgrade -I -n BE_name [ -l error_log ][ -o outfile ]
[ -O "pkginfo_options" ][ pkginst [ pkginst... ] ] [ -N ]
```

The first option, `-C`, for `pkgchk`, or `-I`, for `pkginfo`, indicates the function to perform. The remaining options, shown above, are described as follows:

`-n BE_name`
 Name of the BE on which packages will be checked or on whose packages information will be returned.

`-O "pkgchk_options" or "pkginfo_options"`
 Options passed directly to `pkgchk` (for `-C`) or `pkginfo` (for `-I`). See `pkgchk(1M)` or `pkginfo(1)` for a description of these options.

`pkginst [pkginst...]`
 Zero or more packages to check or for which to have information returned. If you omit package names, `luupgrade` returns information on all of the packages on the BE. Separate multiple package names with spaces.

Check an OS Installation Medium

With the `-c` option, `luupgrade` allows you to check that a local or remote medium, such as a CD, is a valid installation medium. The `-c` option returns useful information about the specified medium. The syntax for this use of `luupgrade` is as follows:

```
luupgrade -c -s path_to_medium [ -l error_log ] [ -o outfile ]
```

The first option, `-c`, indicates the function to perform—to check on an installation medium. The `-s` option, shown above, is described as follows:

`-s path_to_medium` Path name to an installation medium such as a CD-ROM.

EXAMPLES

EXAMPLE 1 Removing, then Adding Packages

The following example removes then adds a set of packages to a boot environment.

```
# luupgrade -P -n second_disk SUNWabc SUNWdef SUNWghi
```

Now, to add the same packages:

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages \
SUNWabc SUNWdef SUNWghi
```

The following command adds the `-O` option to the preceding command. This option passes arguments directly to `pkgadd`.

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages \
-O "-r /net/testmachine/export/responses" SUNWabc SUNWdef SUNWghi
```

See `pkgadd(1M)` for a description of the options for that command.

EXAMPLE 2 Upgrading to a New OS

The following example upgrades the operating environment on a boot environment.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
```

Following the command above you could enter the command below to activate the upgraded BE.

```
# luactivate second_disk
```

luupgrade(1M)

EXAMPLE 2 Upgrading to a New OS *(Continued)*

Then, upon the next reboot, `second_disk` would become the current boot environment. See `luactivate(1M)`.

EXAMPLE 3 Upgrading to a New OS from Multiple CDs

The following example is a variation on the preceding. The OS upgrade resides on two CDs. To begin the upgrade, you enter:

For SPARC machines:

```
# luupgrade -u -n second_disk -s /dev/cdrom/cdrom0/s0
```

For Intel Architecture (IA) machines, replace the `s0` in the argument to `-s` with `s2`.

When the installer is finished with the contents of the first CD, insert the next CD in the drive and enter the following:

```
# luupgrade -i -n second_disk -s /dev/cdrom/cdrom0
```

Note the use of `-i` rather than `-u` in the preceding. Were there additional CDs, you would enter the same command as the one immediately above.

If you are connected to the machine you are upgrading by a `tip(1)` line, you must use the `-O "-nodisplay"` option, as shown below:

```
# luupgrade -u -n second_disk -O "-nodisplay" -s /dev/cdrom/cdrom0/s0  
or s2 for IA machines
```

Insert next CD, then...

```
# luupgrade -i -n second_disk -O "-nodisplay" -s /dev/cdrom/cdrom0
```

EXAMPLE 4 Installing a New OS from a Flash Archive

The following example upgrades the operating environment on a boot environment, using a flash archive.

```
# luupgrade -f -n second_disk \  
-s /net/installmachine/export/solarisX/OS_image \  
-J "archive_location http://example.com/myflash.flar"
```

EXAMPLE 5 Obtaining Information on Packages

The following example runs a `pkgchk` on the packages `SUNWluu` and `SUNWlur`, passing to `pkgchk` the `-v` option.

```
# luupgrade -C -n second_disk -O "-v" SUNWluu SUNWlur
```

The following command runs `pkginfo` on the same set of packages:

```
# luupgrade -I -n second_disk -O "-v" SUNWluu SUNWlur
```

EXAMPLE 5 Obtaining Information on Packages (Continued)

For both commands, if the package names were omitted, `luupgrade` returns package information on all of the packages in the specified BE. See `pkgchk(1M)` and `pkginfo(1)` for a description of the options for those commands.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES `/etc/lutab` list of BEs on the system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWluu |

SEE ALSO `lu(1M)`, `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

WARNINGS For adding packages (`-p`), `luupgrade` requires packages that comply with the SVR4 Advanced Packaging Guidelines. While Sun packages conform to these guidelines, Sun cannot guarantee the conformance of packages from third-party vendors. A non-conformant package can cause the package-addition software in `luupgrade` to fail or, worse, alter the current BE.

luxadm(1M)

| | |
|--------------------|---|
| NAME | luxadm – administration program for the Sun Enterprise Network Array (SENA), RSM, SPARCstorage Array (SSA) subsystems, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices |
| SYNOPSIS | luxadm [<i>options...</i>] <i>subcommand</i> [<i>options...</i>] <i>enclosure</i> [, <i>dev</i>] <i>pathname...</i> |
| DESCRIPTION | <p>The luxadm program is an administrative command that manages the SENA, RSM, SPARCstorage Array subsystems, Sun Fire 880 internal storage subsystem, and individual FC_AL devices. luxadm performs a variety of control and query tasks depending on the command line arguments and options used.</p> <p>The command line must contain a subcommand. The command line may also contain options, usually at least one enclosure name or pathname, and other parameters depending on the subcommand. You need specify only as many characters as are required to uniquely identify a subcommand.</p> <p>Specify the device that a subcommand interacts with by entering a pathname. For the SENA subsystem, a disk device or enclosure services controller may instead be specified by entering the World Wide Name (WWN) for the device or a port to the device. The device may also be specified by entering the name of the SENA enclosure, and an optional identifier for the particular device in the enclosure. The individual FC_AL devices may be specified by entering the WWN for the device or a port to the device.</p> |
| Pathname | <p>Specify the device or controller by either a complete physical pathname or a complete logical pathname.</p> <p>For SENA, a typical physical pathname for a device is:</p> <pre>/devices/sbus@1f,0/SUNW,socal@1,0/sf@0,0/ssd@w2200002037000f96,
0:a,raw</pre> <p>or</p> <pre>/devices/io-unit@f,e0200000/sbi@0,0/SUNW,socal@2,0/sf@0,0/ssd@34,
0:a,raw</pre> <p>For all SENA IBs (Interface Boards) and Sun Fire 880 SES device controllers on the system, a logical link to the physical paths is kept in the directory /dev/es. An example of a logical link is /dev/es.</p> <p>The WWN may be used in place of the pathname to select an FC_AL device, SENA subsystem IB, or Sun Fire 880 internal storage subsystem. The WWN is a unique 16 hexadecimal digit value that specifies either the port used to access the device or the device itself. A typical WWN value is:</p> <pre>2200002037000f96</pre> <p>See NOTES for more information on the WWN formats.</p> |

For the SPARCstorage Array controller, a typical physical pathname is:

```
/devices/. . . /. . . /SUNW,soc@3,0/SUNW,pln@
    axxxxxx,xxxxxx:ctlr
```

whereas, a typical physical pathname for an RSM controller is:

```
/devices/sbus@1f,0/QLGC,isp@1,10000:devctl
```

In order to make it easier to address the SPARCstorage Array or RSM controller, a logical pathname of the form *cN* is supported, where *N* is the logical controller number. `luxadm` uses the *cN* name to find an entry in the `/dev/rdisk` directory of a disk that is attached to the SPARCstorage Array or RSM controller. The `/dev/rdisk` entry is then used to determine the physical name of the SPARCstorage Array or RSM controller.

For a SPARCstorage Array disk, a typical physical pathname is:

```
/devices/. . . /. . . /SUNW,soc@3,0/SUNW,
    pln@xxxxxxx,xxxxxxx/ssd@0,0:c,raw
```

and a typical logical pathname is:

```
/dev/rdisk/c1t0d0s2
```

For an RSM a typical physical pathname is:

```
/devices/sbus@1f,0/QLGC,isp@1,10000/sd@8,0:c,raw
```

and a typical logical pathname is:

```
/dev/rdisk/c2t8d0s2
```

For a disk in a Sun Fire 880 internal storage subsystem, a typical physical pathname is:

```
/devices/pci@8,600000/SUNW,qlc@2/fp@0,0/ssd@w2100002037a6303c,0:a
```

and a typical logical pathname is:

```
/dev/rdisk/c2t8d0s2
```

For individual FC_AL devices, a typical physical pathname is:

```
/devices/sbus@3.0/SUNW,socal@d,10000/sf@0,0/ssd@w2200002037049fc3,0:a,raw
```

and a typical logical pathname is:

```
/dev/rdisk/c1t0d0s2
```

luxadm(1M)

| | |
|--------------------|--|
| Enclosure | <p>For SENA, a device may be identified by its enclosure name and slotname:</p> <p><i>box_name</i>[, <i>fslot_number</i>]
<i>box_name</i>[, <i>rslot_number</i>]</p> <p><i>box_name</i> is the name of the SENA enclosure, as specified by the <i>enclosure_name</i> subcommand. When used without the optional <i>slot_number</i> parameter, the <i>box_name</i> identifies the SENA subsystem IB.</p> <p><i>f</i> or <i>r</i> specifies the front or rear slots in the SENA enclosure.</p> <p><i>slot_number</i> specifies the slot number of the device in the SENA enclosure, 0-6 or 0-10.</p> <p>For a Sun Fire 880 internal storage subsystem, a device may also be identified by its enclosure name and slot name. However, there is only one set of disks:</p> <p><i>box_name</i> [, <i>sslot_number</i>] <i>box_name</i> is the name of the Sun Fire 880 enclosure, as specified by the <i>enclosure_name</i> subcommand. When used without the optional <i>slot_number</i> parameter, <i>box_name</i> identifies the Sun Fire 880 internal storage subsystem enclosure services device. Use <i>s</i> to specify the disk slot number in the Sun Fire 880 internal storage subsystem, 0 - 11.</p> <p>See <code>disks(1M)</code> and <code>devlinks(1M)</code> for additional information on logical names for disks and subsystems.</p> |
| OPTIONS | <p>The following options are supported by all subcommands:</p> <p>-e Expert mode. This option is not recommended for the novice user.</p> <p>-v Verbose mode.</p> <p>Options that are specific to particular subcommands are described with the subcommand in the <code>USAGE</code> section.</p> |
| OPERANDS | <p>The following operands are supported:</p> <p><i>enclosure</i> The <i>box_name</i> of the SENA. or Sun Fire 880 internal storage subsystem.</p> <p><i>pathname</i> The logical or physical path of a SENA IB,, Sun Fire 880 internal storage subsystem, SPARCstorage Array or RSM controller (<i>cN</i> name) or disk device. <i>pathname</i> can also be the WWN of a SENA IB, SENA disk, or individual FC_AL device.</p> |
| Subcommands | <p><code>display enclosure[<i>dev</i>]... <i>pathname</i>...</code>
<code>display -p <i>pathname</i>...</code>
<code>display -r enclosure[<i>dev</i>]... <i>pathname</i>...</code>
<code>display -v enclosure[<i>dev</i>]... <i>pathname</i>...</code>
Displays enclosure or device specific data.</p> |

Subsystem data consists of enclosure environmental sense information and status for all subsystem devices, including disks.

Disk data consists of inquiry, capacity, and configuration information.

-p

Displays performance information for the device or subsystem specified by *pathname*. This option only applies to subsystems that accumulate performance information.

-r

Displays error information for the FC_AL device specified by the *pathname*, or, if the path is a SENA, for all devices on the loop. The **-r** option only applies to SENA subsystems and individual FC_AL devices.

-v

Displays in verbose mode, including mode sense data.

`download [-s] [-w WWN] [-f filename_path] enclosure . . .`

Download the prom image pointed to by *filename_path* to the SENA subsystem Interface Board unit, the Sun Fire 880 internal storage subsystem, or the SPARCstorage Array controllers specified by the enclosure or *pathname*. The SPARCstorage Array must be reset in order to use the downloaded code.

When the SENA's download is complete, the SENA will be reset and the downloaded code executed. If no filename is specified, the default prom image will be used. The default prom image for the SPARCstorage Array controller is in `usr/lib/firmware/ssa/ssafirmware`. The default prom image for the SENA is in the directory `usr/lib/locale/C/LC_MESSAGES` and is named `ibfirmware`

When the Sun Fire 880 internal storage subsystem's download is complete, the subsystem resets and the downloaded code begins execution. The default firmware image for the Sun Fire 880 internal storage subsystem is in:

`/usr/platform/SUNW,Sun-Fire-880/lib/images/int_fcbpl_fw`.

-s

Save. The **-s** option is used to save the downloaded firmware in the FEPRM. If **-s** is not specified, the downloaded firmware will not be saved across power cycles.

The **-s** option does not apply to the SPARCstorage Array controller as it *always* writes the downloaded firmware into the FEPRM.

The **-s** option does not apply to the Sun Fire 880 internal storage subsystem as it always stores downloaded firmware in the flash memory.

When using the **-s** option, the `download` subcommand modifies the FEPRM on the subsystem and should be used with *caution*.

`-w WWN`

Change the SPARCstorage Array controller's World Wide Name. *WWN* is a 12-digit hex number; leading zeros are required. The `-w` option applies only to the SPARCstorage Array. The new SPARCstorage Array controller's image will have the least significant 6 bytes of the 8-byte World Wide Name modified to *WWN*.

`enclosure_name new_name enclosure | pathname`

Change the enclosure name of the enclosure or enclosures specified by the enclosure or pathname. The new name (*new_name*) must be 16 or less characters. Only alphabetic or numeric characters are acceptable. This subcommand applies only to the SENA and the Sun Fire 880 internal storage subsystem.

`failover primary | secondary pathname`

Select which Sun Storage T3 storage array partner group controller accesses a given logical volume. If *primary* is specified, the logical volume is accessed through the primary controller. If *secondary* is specified, the logical volume is accessed through the secondary controller specified by *pathname*.

`fc_s_download [-F] [-f fcode-file]`

Download the fcode contained in the file *fcode-file* into *all* the FC/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use `fc_s_download` *only* in single-user mode. Using `fc_s_download` to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-f fcode-file`

When invoked without the `-f fcode-file` option, the current version of the fcode in each FC/S Sbus card is printed.

`-F`

Forcibly downloads the fcode, but the command still expects user confirmation before the download. The version of the FC/S Sbus Cards fcode that was released with this version of the Operating System is kept in the directory `usr/lib/firmware/fc_s` and is named `fc_s_fcode`.

`fcal_s_download [-f fcode-file]`

Download the fcode contained in the file *fcode-file* into *all* the FC100/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use `fcal_s_download` *only* in single-user mode. Using `fcal_s_download` to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-f fcode-file`
 When invoked without the `-f` option, the current version of the fcode in each FC100/S Sbus card is printed.

`fcode_download -p`
`fcode_download -d dir-name`
 Locate the installed FC/S, FC100/S, FC100/P, or FC100/2P host bus adapter cards and download the FCode files in *dir-name* to the appropriate cards. The command determines the correct card for each type of file, and is interactive. User confirmation is required before downloading the FCode to each device.

Use `fcode_download` to load FCode only in single-user mode. Using `fcode_download` to update a host adapter while there is I/O activity through that adapter causes the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-d dir-name`
 Download the FCode files contained in the directory *dir-name* to the appropriate adapter cards.

`-p`
 Prints the current version of FCode loaded on each card. No download is performed.

`inquiry enclosure[,dev] ... | pathname ...`
 Display the inquiry information for the selected device specified by the enclosure or *pathname*.

`insert_device [enclosure,dev ...]`
 Assist the user in the hot insertion of a new device or a chain of new devices. Refer to NOTES for limitations on hotplug operations. This subcommand applies only to the SENA, Sun Fire 880 internal storage subsystem, RSM, and individual FC_AL drives. RSM, and individual FC_AL drives. For the SENA, if more than one enclosure has been specified, concurrent hot insertions on multiple busses can be performed. With no arguments to the subcommand, entire enclosures or individual FC_AL drives can be inserted. For the RSM, only one controller can be specified. For the SENA or the Sun Fire 880 internal storage subsystem, this subcommand guides the this subcommand guides the user interactively through the hot insertion steps of a new device or chain of devices. If a list of disks was entered it will ask the user to verify the list of devices to be inserted is correct, at which point the user can continue or quit. It then interactively asks the user to insert the disk(s) or enclosure(s) and then creates and displays the logical pathnames for the devices.

For the RSM, the following steps are taken:

- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform the user that the device can be safely inserted .
- Request confirmation from the user that the device has been inserted.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Create the logical device name for the new device.

`led enclosure,dev ... | pathname ...`

Display the current state of the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_blink enclosure,dev ... | pathname ...`

Requests the subsystem to start blinking the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_off enclosure,dev ... | pathname ...`

Requests the subsystem to disable (turn off) the LED associated with the disk specified by the enclosure or pathname. On a SENA subsystem, this may or may not cause the LED to turn off or stop blinking depending on the state of the SENA subsystem. Refer to the SENA Array Installation and Service Manual (p/n 802-7573). This subcommand only applies to subsystems that support this functionality.

`led_on pathname ...`

Requests the subsystem to enable (turn on) the LED associated with the disk specified by the pathname. This subcommand only applies to subsystems that support this functionality.

`power_off [-F] enclosure[,dev] ... | pathname ...`

`power_off pathname [enclosure-port] ... | controller tray-number`

When a SENA is addressed, this subcommand causes the SENA subsystem to go into the power-save mode. The SENA drives are not available when in the power-save mode. When an Enclosure Services card within the SPARCstorage Array is addressed, the RSM tray is powered down. When a drive in a SENA is addressed the drive is set to the drive off/unmated state. In the drive off/unmated state, the drive is spun down (stopped) and in bypass mode. This command does not apply to the Sun Fire 880 internal storage subsystem.

-F

The force option only applies to the SENA. Instructs luxadm to attempt to power off one or more devices even if those devices are being used by this host (and are, therefore, busy).

Warning: Powering off a device which has data that is currently being used will cause unpredictable results. Users should attempt to power off the device normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal checks.

`power_on enclosure[, dev] . .`

Causes the SENA subsystem to go out of the power-save mode, when this subcommand is addressed to a SENA. There is no programmatic way to power on the SPARCstorage Array RSM tray. When this subcommand is addressed to a drive the drive is set to its normal start-up state. This command does not apply to the Sun Fire 880 internal storage subsystem.

probe [-p]

Finds and displays information about all attached SENA subsystems, Sun Fire 880 internal storage subsystems, and individual FC_AL devices, including the logical pathname, the WWNs, and enclosure names. This subcommand warns the user if it finds different SENAs with the same enclosure names.

-p

Includes the physical pathname in the display.

qlgc_s_download [-f *fcode-file*]

Download the FCode contained in the file *fcode-file* into all the FC100/P, FC100/2P PCI host adapter cards. This command is interactive and expects user confirmation before downloading the FCode to each device. Only use `qlgc_s_download` in single-user mode. Using `qlgc_s_download` to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

-f *fcode-file*

When invoked without the -f option, the current version of the FCode in each FC100/P, FC100/2P PCI card is printed.

release *pathname*

Release a reservation held on the specified disk. The pathname should be the physical or logical pathname for the disk. If the pathname is of the SPARCstorage Array controller, then all of the disks in the SPARCstorage Array will be released.

This subcommand is included for historical and diagnostic purposes only.

remove_device [-F] *enclosure[,dev]* ... | *pathname* ...

Assists the user in hot removing a device or a chain of devices. This subcommand can also be used to remove entire enclosures. This subcommand applies to the SENA, Sun Fire 880 internal storage subsystem, RSM, and individual FC_AL drives. Refer to NOTES for limitations on hotplug operations. For the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL devices, this subcommand guides the user through the hot removal of a device or devices. During execution it will ask the user to verify the list of devices to be removed is correct, at which point the user can continue or quit. It then prepares the disk(s) or enclosure(s) for removal and interactively asks the user to remove the disk(s) or enclosure(s).

For the RSM, the steps taken are:

- Take the device offline.
- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform user that the device can be safely removed.
- Request confirmation from the user that the device has been removed.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Bring the (now removed) device back online.
- Remove the logical device name for the removed device.

For Multi-Hosted disk, the steps taken are:

- Issue the `luxadm remove_device` command on the first host. When prompted to continue, wait.
- Issue the `luxadm remove_device` command on the secondary hosts. When prompted to continue, wait.
- Continue with the `remove_device` command on the first host. Remove the device when prompted to do so.
- Complete the `luxadm remove_device` command on the additional hosts.

-F

Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are being used by this host (and are, therefore, *busy* or *reserved*), to *force* the hotplugging operation.

Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

`replace_device [-F] pathname`

This subcommand applies only to the RSM. Refer to NOTES for limitations on hotplug operations. This subcommand guides the user interactively through the hot replacement of a device.

For the RSM, the steps taken are:

- Take the device offline.
- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform user that the device can be safely replaced.
- Request confirmation from the user that the device has been replaced.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Bring the device back online.

-F

Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are *busy* or *reserved*, (that is, to *force* the hotplugging operation).

Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

`reserve pathname`

Reserve the specified disk for exclusive use by the issuing host. The pathname used should be the physical or logical pathname for the disk. If the pathname is of the SPARCstorage Array controller, then all of the disks in the SPARCstorage Array will be reserved.

This subcommand is included for historical and diagnostic purposes only.

**SPARCstorage
Array
Subcommands**

`set_boot_dev [-y] pathname`

Set the boot-device variable in the system PROM to the physical device name specified by *pathname*, which can be a block special device or the pathname of the directory on which the boot file system is mounted. The command normally runs interactively requesting confirmation for setting the default boot-device in the PROM. The `-y` option can be used to run it non-interactively, in which case no confirmation is requested or required.

`start [-t tray-number] pathname . . .`

Spin up the specified disk(s). If *pathname* specifies the SPARCstorage Array controller, this action applies to all disks in the SPARCstorage Array.

`-t` Spin up all disks in the tray specified by *tray-number*. *pathname* must specify the SPARCstorage Array controller.

`stop [-t tray-number] pathname . . .`

Spin down the specified disk(s). If *pathname* specifies the SPARCstorage Array controller, this action applies to all disks in the SPARCstorage Array.

`-t` Spin down all disks in the tray specified by *tray-number*. *pathname* must specify the SPARCstorage Array controller.

`fast_write [-s] -c pathname`

`fast_write [-s] -d pathname`

`fast_write [-s] -e pathname`

Enable or disable the use of the NVRAM to enhance the performance of writes in the SPARCstorage Array. *pathname* refers to the SPARCstorage Array controller or to an individual disk.

`-s` Cause the SPARCstorage Array to save the change so it will persist across power-cycles.

`-c` Enable fast writes for synchronous writes only.

`-d` Disable fast writes.

`-e` Enable fast writes.

`nvrाम_data pathname`

Display the amount of fast write data in the NVRAM for the specified disk. This command can only be used for an individual disk.

`perf_statistics -d pathname`

`perf_statistics -e pathname`

Enable or disable the accumulation of performance statistics for the specified SPARCstorage Array controller. The accumulation of performance statistics must be

luxadm(1M)

enabled before using the `display -p` subcommand. This subcommand can be issued only to the SPARCstorage Array controller.

`-d`

Disable the accumulation of performance statistics.

`-e`

Enable the accumulation of performance statistics.

`purge pathname`

Purge any fast write data from NVRAM for one disk, or all disks if the controller is specified. This option should be used with caution, usually only when a drive has failed.

`sync_cache pathname`

Flush all outstanding writes for the specified disk from NVRAM to the media. If `pathname` specifies the controller, this action applies to all disks in the SPARCstorage Array subsystem.

**Enclosure Services
Card
Subcommands**

The `env_display` and `alarm*` subcommands apply only to an Enclosure Services Card (SES) in a RSM tray in a SPARCstorage Array. The RSM tray is addressed by using the logical or physical path of the SES device or by specifying the controller followed by the tray number. The controller is addressed by `cN` or the physical path to the SSA's controller.

`alarm pathname | controller tray_number`

Display the current state of audible alarm.

`alarm_off pathname | controller tray_number`

Disable the audible alarm for this RSM tray.

`alarm_on pathname | controller tray_number`

Enable the audible alarm for this RSM tray.

`alarm_set controller-pathname | controller tray_number [seconds]`

Set the audible alarm setting to seconds.

`env_display pathname | controller tray_number`

Display the environmental information for the specified unit.

**SENA, Sun Fire
880 Internal
Storage
Subsystem, and
Individual FC_AL
Drive Expert Mode
Subcommands**

The following subcommands are for expert use only, and are applicable only to the SENA, Sun Fire 880 internal storage subsystem, and fiber channel loops. They should only be used by users that are knowledgeable about the SENA subsystem and fiber channel loops.
