Index 669

Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the `intro` pages for more information and detail about each section, and `man(1)` for more information about man pages in general.

NAME	This section gives the names of the commands or functions documented, followed by a brief description of what they do.
SYNOPSIS	This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.
	The following special characters are used in this section:
[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.
. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename ...".
	Separator. Only one of the arguments separated by this character can be specified at a time.
{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

PROTOCOL	This section occurs only in subsection 3R to indicate the protocol description file.
DESCRIPTION	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.
IOCTL	This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the <code>ioctl(2)</code> system call is called <code>ioctl</code> and generates its own heading. <code>ioctl</code> calls for a specific device are listed alphabetically (on the man page for that specific device). <code>ioctl</code> calls are used for a particular class of devices all of which have an <code>io</code> ending, such as <code>mtio(7I)</code> .
OPTIONS	This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.
OPERANDS	This section lists the command operands and describes how they affect the actions of the command.
OUTPUT	This section describes the output – standard output, standard error, or output files – generated by the command.
RETURN VALUES	If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.
ERRORS	On failure, most functions place an error code in the global variable <code>errno</code> indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than

	one condition can cause the same error, each condition is described in a separate paragraph under the error code.
USAGE	This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality: Commands Modifiers Variables Expressions Input Grammar
EXAMPLES	This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as <code>example%</code> , or if the user must be superuser, <code>example#</code> . Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.
ENVIRONMENT VARIABLES	This section lists any environment variables that the command or function affects, followed by a brief description of the effect.
EXIT STATUS	This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.
FILES	This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.
ATTRIBUTES	This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See <code>attributes(5)</code> for more information.
SEE ALSO	This section lists references to other man pages, in-house documentation, and outside publications.

DIAGNOSTICS	This section lists diagnostic messages with a brief explanation of the condition causing the error.
WARNINGS	This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.
NOTES	This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.
BUGS	This section describes known bugs and, wherever possible, suggests workarounds.

Introduction

Intro(4)

NAME	Intro – introduction to file formats
DESCRIPTION	<p>This section outlines the formats of various files. The C structure declarations for the file formats are given where applicable. Usually, the headers containing these structure declarations can be found in the directories <code>/usr/include</code> or <code>/usr/include/sys</code>. For inclusion in C language programs, however, the syntax <code>#include <filename.h></code> or <code>#include <sys/filename.h></code> should be used.</p> <p>Because the operating system now allows the existence of multiple file system types, there are several instances of multiple manual pages with the same name. These pages all display the name of the FSType to which they pertain, in the form <code>name_fstype</code> at the top of the page. For example, <code>fs_ufs(4)</code>.</p>

File Formats

admin(4)

NAME	admin – installation defaults file												
DESCRIPTION	<p>admin is a generic name for an ASCII file that defines default installation actions by assigning values to installation parameters. For example, it allows administrators to define how to proceed when the package being installed already exists on the system.</p> <p><code>/var/sadm/install/admin/default</code> is the default admin file delivered with this release. The default file is not writable, so to assign values different from this file, create a new admin file. There are no naming restrictions for admin files. Name the file when installing a package with the <code>-a</code> option of <code>pkgadd(1M)</code>. If the <code>-a</code> option is not used, the default admin file is used.</p> <p>Each entry in the admin file is a line that establishes the value of a parameter in the following form:</p> <p><i>param=value</i></p> <p>Eleven parameters can be defined in an admin file, but it is not required to assign values to all eleven parameters. If a value is not assigned, <code>pkgadd(1M)</code> asks the installer how to proceed.</p> <p>The eleven parameters and their possible values are shown below except as noted. They may be specified in any order. Any of these parameters (except the <code>mail</code> parameter) can be assigned the value <code>ask</code>, which means that if the situation occurs the installer is notified and asked to supply instructions at that time (see NOTES).</p> <table><tr><td><code>basedir</code></td><td>Indicates the base directory where relocatable packages are to be installed. If there is no <code>basedir</code> entry in the file, the installer will be prompted for a path name, as if the file contained the entry <code>basedir=ask</code>. This parameter can also be set to <code>default</code> (entry is <code>basedir=default</code>). In this instance, the package is installed into the base directory specified by the <code>BASEDIR</code> parameter in the <code>pkginfo(4)</code> file.</td></tr><tr><td><code>mail</code></td><td>Defines a list of users to whom mail should be sent following installation of a package. If the list is empty, no mail is sent. If the parameter is not present in the admin file, the default value of <code>root</code> is used. The <code>ask</code> value cannot be used with this parameter.</td></tr><tr><td><code>runlevel</code></td><td>Indicates resolution if the run level is not correct for the installation or removal of a package. Options are: <table><tr><td><code>nocheck</code></td><td>Do not check for run level.</td></tr><tr><td><code>quit</code></td><td>Abort installation if run level is not met.</td></tr></table></td></tr><tr><td><code>conflict</code></td><td>Specifies what to do if an installation expects to overwrite a previously installed file, thus creating a conflict between packages. Options are:</td></tr></table>	<code>basedir</code>	Indicates the base directory where relocatable packages are to be installed. If there is no <code>basedir</code> entry in the file, the installer will be prompted for a path name, as if the file contained the entry <code>basedir=ask</code> . This parameter can also be set to <code>default</code> (entry is <code>basedir=default</code>). In this instance, the package is installed into the base directory specified by the <code>BASEDIR</code> parameter in the <code>pkginfo(4)</code> file.	<code>mail</code>	Defines a list of users to whom mail should be sent following installation of a package. If the list is empty, no mail is sent. If the parameter is not present in the admin file, the default value of <code>root</code> is used. The <code>ask</code> value cannot be used with this parameter.	<code>runlevel</code>	Indicates resolution if the run level is not correct for the installation or removal of a package. Options are: <table><tr><td><code>nocheck</code></td><td>Do not check for run level.</td></tr><tr><td><code>quit</code></td><td>Abort installation if run level is not met.</td></tr></table>	<code>nocheck</code>	Do not check for run level.	<code>quit</code>	Abort installation if run level is not met.	<code>conflict</code>	Specifies what to do if an installation expects to overwrite a previously installed file, thus creating a conflict between packages. Options are:
<code>basedir</code>	Indicates the base directory where relocatable packages are to be installed. If there is no <code>basedir</code> entry in the file, the installer will be prompted for a path name, as if the file contained the entry <code>basedir=ask</code> . This parameter can also be set to <code>default</code> (entry is <code>basedir=default</code>). In this instance, the package is installed into the base directory specified by the <code>BASEDIR</code> parameter in the <code>pkginfo(4)</code> file.												
<code>mail</code>	Defines a list of users to whom mail should be sent following installation of a package. If the list is empty, no mail is sent. If the parameter is not present in the admin file, the default value of <code>root</code> is used. The <code>ask</code> value cannot be used with this parameter.												
<code>runlevel</code>	Indicates resolution if the run level is not correct for the installation or removal of a package. Options are: <table><tr><td><code>nocheck</code></td><td>Do not check for run level.</td></tr><tr><td><code>quit</code></td><td>Abort installation if run level is not met.</td></tr></table>	<code>nocheck</code>	Do not check for run level.	<code>quit</code>	Abort installation if run level is not met.								
<code>nocheck</code>	Do not check for run level.												
<code>quit</code>	Abort installation if run level is not met.												
<code>conflict</code>	Specifies what to do if an installation expects to overwrite a previously installed file, thus creating a conflict between packages. Options are:												

	nocheck	Do not check for conflict; files in conflict will be overwritten.
	quit	Abort installation if conflict is detected.
	nochange	Override installation of conflicting files; they will not be installed.
setuid		Checks for executables which will have setuid or setgid bits enabled after installation. Options are:
	nocheck	Do not check for setuid executables.
	quit	Abort installation if setuid processes are detected.
	nochange	Override installation of setuid processes; processes will be installed without setuid bits enabled.
action		Determines if action scripts provided by package developers contain possible security impact. Options are:
	nocheck	Ignore security impact of action scripts.
	quit	Abort installation if action scripts may have a negative security impact.
partial		Checks to see if a version of the package is already partially installed on the system. Options are:
	nocheck	Do not check for a partially installed package.
	quit	Abort installation if a partially installed package exists.
instance		Determines how to handle installation if a previous version of the package (including a partially installed instance) already exists. Options are:
	quit	Exit without installing if an instance of the package already exists (does not overwrite existing packages).
	overwrite	Overwrite an existing package if only one instance exists. If there is more than one instance, but only one has the same architecture, it overwrites that instance. Otherwise, the installer is prompted with existing instances and asked which to overwrite.
	unique	Do not overwrite an existing instance of a package. Instead, a new instance of the package is created. The new instance will be

admin(4)

		assigned the next available instance identifier.
<code>idepend</code>	Controls resolution if other packages depend on the one to be installed. Options are:	
	<code>nocheck</code>	Do not check package dependencies.
	<code>quit</code>	Abort installation if package dependencies are not met.
<code>rdepend</code>	Controls resolution if other packages depend on the one to be removed. Options are:	
	<code>nocheck</code>	Do not check package dependencies.
	<code>quit</code>	Abort removal if package dependencies are not met.
<code>space</code>	Controls resolution if disk space requirements for package are not met. Options are:	
	<code>nocheck</code>	Do not check space requirements (installation fails if it runs out of space).
	<code>quit</code>	Abort installation if space requirements are not met.

EXAMPLES **EXAMPLE 1** Sample of admin file.

Below is a sample admin file.

```
basedir=default
runlevel=quit
conflict=quit
setuid=quit
action=quit
partial=quit
instance=unique
idepend=quit
rdepend=quit
space=quit
```

SEE ALSO `pkgadd(1M)`, `pkginfo(4)`

NOTES The value `ask` should not be defined in an admin file that will be used for non-interactive installation (since by definition, there is no installer interaction). Doing so causes installation to fail when input is needed.

NAME	alias – alias table file of encoding names				
SYNOPSIS	<code>/usr/lib/iconv/alias</code>				
DESCRIPTION	<p>This file contains the alias table of encoding names for <code>iconv_open(3C)</code>.</p> <p>The format of the alias table is as follows:</p> <pre>"%s %s\n", <variant encoding name>, <canonical encoding name></pre> <p>The string specified for the variant encoding name is case-insensitive. A line beginning with <code>#</code> is treated as a comment.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Interface Stability	Evolving
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Interface Stability	Evolving				
SEE ALSO	<code>iconv(3C)</code> , <code>iconv_close(3C)</code> , <code>iconv_open(3C)</code> , <code>attributes(5)</code>				

aliases(4)

NAME	aliases, addresses, forward – addresses and aliases for sendmail								
SYNOPSIS	<pre>/etc/mail/aliases /etc/mail/aliases.db /etc/mail/aliases.dir /etc/mail/aliases.pag ~/ .forward</pre>								
DESCRIPTION	<p>These files contain mail addresses or aliases, recognized by <code>sendmail(1M)</code> for the local host:</p> <table><tr><td><code>/etc/passwd</code></td><td>Mail addresses (usernames) of local users.</td></tr><tr><td><code>/etc/mail/aliases</code></td><td>Aliases for the local host, in ASCII format. Root can edit this file to add, update, or delete local mail aliases.</td></tr><tr><td><code>/etc/mail/aliases.{dir , pag}</code></td><td>The aliasing information from <code>/etc/mail/aliases</code>, in binary <code>ndbm(3C)</code> format for use by <code>sendmail(1M)</code>. The program <code>newaliases(1M)</code> maintains these files.</td></tr><tr><td><code>/etc/mail/aliases.db</code></td><td>The aliasing information from <code>/etc/mail/aliases</code>, in binary, Berkeley DataBase format for use by <code>sendmail(1M)</code>. The program maintains these files.</td></tr></table> <p>Depending on the configuration of the <code>AliasFile</code> option in <code>/etc/mail/sendmail.cf</code>, either the single file <code>aliases.db</code> or the pair of files <code>aliases.{dir , pag}</code> is generated by <code>newaliases(1M)</code>. As shipped with Solaris, <code>sendmail(1M)</code> supports both formats. If neither is specified, the Berkeley DataBase format which generates the single <code>.db</code> file is used.</p> <p><code>~/ .forward</code> Addresses to which a user's mail is forwarded (see Automatic Forwarding).</p> <p>In addition, the NIS name services aliases map <code>mail.aliases</code>, and the NIS+ <code>mail_aliases</code> table, both contain addresses and aliases available for use across the network.</p>	<code>/etc/passwd</code>	Mail addresses (usernames) of local users.	<code>/etc/mail/aliases</code>	Aliases for the local host, in ASCII format. Root can edit this file to add, update, or delete local mail aliases.	<code>/etc/mail/aliases.{dir , pag}</code>	The aliasing information from <code>/etc/mail/aliases</code> , in binary <code>ndbm(3C)</code> format for use by <code>sendmail(1M)</code> . The program <code>newaliases(1M)</code> maintains these files.	<code>/etc/mail/aliases.db</code>	The aliasing information from <code>/etc/mail/aliases</code> , in binary, Berkeley DataBase format for use by <code>sendmail(1M)</code> . The program maintains these files.
<code>/etc/passwd</code>	Mail addresses (usernames) of local users.								
<code>/etc/mail/aliases</code>	Aliases for the local host, in ASCII format. Root can edit this file to add, update, or delete local mail aliases.								
<code>/etc/mail/aliases.{dir , pag}</code>	The aliasing information from <code>/etc/mail/aliases</code> , in binary <code>ndbm(3C)</code> format for use by <code>sendmail(1M)</code> . The program <code>newaliases(1M)</code> maintains these files.								
<code>/etc/mail/aliases.db</code>	The aliasing information from <code>/etc/mail/aliases</code> , in binary, Berkeley DataBase format for use by <code>sendmail(1M)</code> . The program maintains these files.								
Addresses	As distributed, <code>sendmail(1M)</code> supports the following types of addresses:								
Local Usernames	<code>username</code>								

	Each local <i>username</i> is listed in the local host's <code>/etc/passwd</code> file.
Local Filenames	<i>pathname</i>
	Messages addressed to the absolute <i>pathname</i> of a file are appended to that file.
Commands	<i>command</i>
	If the first character of the address is a vertical bar (), <code>sendmail(1M)</code> pipes the message to the standard input of the <i>command</i> the bar precedes.
Internet-standard Addresses	<i>username@domain</i>
	If <i>domain</i> does not contain any '.' (dots), then it is interpreted as the name of a host in the current domain. Otherwise, the message is passed to a <i>mailhost</i> that determines how to get to the specified domain. Domains are divided into subdomains separated by dots, with the top-level domain on the right.
	For example, the full address of John Smith could be:
	<code>js@jsmachine.Podunk-U.EDU</code>
	if he uses the machine named <code>jsmachine</code> at Podunk University.
uucp Addresses	<code>... [host!] host!username</code>
	These are sometimes mistakenly referred to as "Usenet" addresses. <code>uucp(1C)</code> provides links to numerous sites throughout the world for the remote copying of files.
	Other site-specific forms of addressing can be added by customizing the <code>sendmail.cf</code> configuration file. See <code>sendmail(1M)</code> for details. Standard addresses are recommended.
Local Aliases	<code>/etc/mail/aliases</code> is formatted as a series of lines of the form
	<code>aliasname: address[, address]</code>
	<i>aliasname</i> is the name of the alias or alias group, and <i>address</i> is the address of a recipient in the group. Aliases can be nested. That is, an <i>address</i> can be the name of another alias group. Because of the way <code>sendmail(1M)</code> performs mapping from upper-case to lower-case, an <i>address</i> that is the name of another alias group must not contain any upper-case letters.
	Lines beginning with white space are treated as continuation lines for the preceding alias. Lines beginning with # are comments.

aliases(4)

Special Aliases

An alias of the form:

```
owner-aliasname : address
```

sendmail directs error-messages resulting from mail to *aliasname* to *address*, instead of back to the person who sent the message. sendmail rewrites the SMTP envelope sender to match this, so owner-aliasname should always point to alias-request, and alias-request should point to the owner's actual address:

```
owner-aliasname:      aliasname-request
aliasname-request    address
```

An alias of the form:

```
aliasname : :include:pathname
```

with colons as shown, adds the recipients listed in the file *pathname* to the *aliasname* alias. This allows a private list to be maintained separately from the aliases file.

NIS and NIS+ Domain Aliases

The aliases file on the master NIS server is used for the *mail.aliases* NIS map, which can be made available to every NIS client. The *mail_aliases* table serves the same purpose on a NIS+ server. Thus, the */etc/mail/aliases** files on the various hosts in a network will one day be obsolete. Domain-wide aliases should ultimately be resolved into usernames on specific hosts. For example, if the following were in the domain-wide alias file:

```
jsmith:js@jsmachine
```

then any NIS or NIS+ client could just mail to jsmith and not have to remember the machine and username for John Smith.

If a NIS or NIS+ alias does not resolve to an address with a specific host, then the name of the NIS or NIS+ domain is used. There should be an alias of the domain name for a host in this case.

For example, the alias:

```
jsmith:root
```

sends mail on a NIS or NIS+ client to root@podunk-u if the name of the NIS or NIS+ domain is podunk-u.

Automatic Forwarding

When an alias (or address) is resolved to the name of a user on the local host, sendmail(1M) checks for a *~/forward* file, owned by the intended recipient, in that

user's home directory, and with universal read access. This file can contain one or more addresses or aliases as described above, each of which is sent a copy of the user's mail.

Care must be taken to avoid creating addressing loops in the `~/ .forward` file. When forwarding mail between machines, be sure that the destination machine does not return the mail to the sender through the operation of any NIS aliases. Otherwise, copies of the message may "bounce." Usually, the solution is to change the NIS alias to direct mail to the proper destination.

A backslash before a username inhibits further aliasing. For instance, to invoke the vacation program, user `js` creates a `~/ .forward` file that contains the line:

```
\js, "|/usr/ucb/vacation js"
```

so that one copy of the message is sent to the user, and another is piped into the vacation program.

FILES	<code>/etc/passwd</code>	Password file
	<code>/etc/nsswitch.conf</code>	Name service switch configuration file
	<code>/etc/mail/aliases</code>	Mail aliases file (ascii)
	<code>/etc/mail/aliases.db</code>	Database of mail aliases (binary)
	<code>/etc/mail/aliases.dir</code>	Database of mail aliases (binary)
	<code>/etc/mail/aliases.pag</code>	Database of mail aliases (binary)
	<code>/etc/mail/sendmail.cf</code>	sendmail configuration file
	<code>~/ .forward</code>	Forwarding information file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsndmr

SEE ALSO `passwd(1)`, `uucp(1C)`, `vacation(1)`, `newaliases(1M)`, `sendmail(1M)`, `ndbm(3C)`, `getusershell(3C)`, `passwd(4)`, `shells(4)`, `attributes(5)`

NOTES Because of restrictions in `ndbm(3C)`, a single alias cannot contain more than about 1000 characters (if this format is used). The Berkeley DataBase format does not have any such restriction. Nested aliases can be used to circumvent this limit.

For aliases which result in piping to a program or concatenating a file, the shell of the controlling user must be allowed. Which shells are and are not allowed are determined by `getusershell(3C)`.

a.out(4)

NAME a.out – Executable and Linking Format (ELF) files

SYNOPSIS `#include <elf.h>`

DESCRIPTION The file name `a.out` is the default output file name from the link editor, `ld(1)`. The link editor will make an `a.out` executable if there were no errors in linking. The output file of the assembler, `as(1)`, also follows the format of the `a.out` file although its default file name is different.

Programs that manipulate ELF files may use the library that `elf(3ELF)` describes. An overview of the file format follows. For more complete information, see the references given below.

Linking View	Execution View
ELF header	ELF header
Program header table <i>optional</i>	Program header table
Section 1	Segment 1
...	
Section <i>n</i>	Segment 2
...	
...	...
Section header table	Section header table <i>optional</i>

An ELF header resides at the beginning and holds a “road map” describing the file’s organization. Sections hold the bulk of object file information for the linking view: instructions, data, symbol table, relocation information, and so on. Segments hold the object file information for the program execution view. As shown, a segment may contain one or more sections.

A program header table, if present, tells the system how to create a process image. Files used to build a process image (execute a program) must have a program header table; relocatable files do not need one. A section header table contains information describing the file’s sections. Every section has an entry in the table; each entry gives information such as the section name, the section size, etc. Files used during linking must have a section header table; other object files may or may not have one.

Although the figure shows the program header table immediately after the ELF header, and the section header table following the sections, actual files may differ. Moreover, sections and segments have no specified order. Only the ELF header has a fixed position in the file.

When an a.out file is loaded into memory for execution, three logical segments are set up: the text segment, the data segment (initialized data followed by uninitialized, the latter actually being initialized to all 0's), and a stack. The text segment is not writable by the program; if other processes are executing the same a.out file, the processes will share a single text segment.

The data segment starts at the next maximal page boundary past the last text address. If the system supports more than one page size, the "maximal page" is the largest supported size. When the process image is created, the part of the file holding the end of text and the beginning of data may appear twice. The duplicated chunk of text that appears at the beginning of data is never executed; it is duplicated so that the operating system may bring in pieces of the file in multiples of the actual page size without having to realign the beginning of the data section to a page boundary. Therefore, the first data address is the sum of the next maximal page boundary past the end of text plus the remainder of the last text address divided by the maximal page size. If the last text address is a multiple of the maximal page size, no duplication is necessary. The stack is automatically extended as required. The data segment is extended as requested by the `brk(2)` system call.

NAME	asetenv – ASET environment file																						
SYNOPSIS	<code>/usr/aset/asetenv</code>																						
DESCRIPTION	<p>The <code>asetenv</code> file is located in <code>/usr/aset</code>, the default operating directory of the Automated Security Enhancement Tool (ASET). An alternative working directory can be specified by the administrators through the <code>aset -d</code> command or the <code>ASETDIR</code> environment variable. See <code>aset(1M)</code>. <code>asetenv</code> contains definitions of environment variables for ASET.</p> <p>There are 2 sections in this file. The first section is labeled <i>User Configurable Parameters</i>. It contains, as the label indicates, environment variables that the administrators can modify to customize ASET behavior to suit their specific needs. The second section is labeled <i>ASET Internal Environment Variables</i> and should not be changed. The configurable parameters are explained as follows:</p> <table border="0"> <tr> <td style="vertical-align: top;">TASK</td> <td> <p>This variable defines the list of tasks that <code>aset</code> will execute the next time it runs. The available tasks are:</p> <table border="0"> <tr> <td><code>tune</code></td> <td>Tighten system files.</td> </tr> <tr> <td><code>usrgrp</code></td> <td>Check user/group.</td> </tr> <tr> <td><code>sysconf</code></td> <td>Check system configuration file.</td> </tr> <tr> <td><code>env</code></td> <td>Check environment.</td> </tr> <tr> <td><code>cklist</code></td> <td>Compare system files checklist.</td> </tr> <tr> <td><code>eeprom</code></td> <td>Check <code>eeprom(1M)</code> parameters.</td> </tr> <tr> <td><code>firewall</code></td> <td>Disable forwarding of IP packets.</td> </tr> </table> </td> </tr> <tr> <td style="vertical-align: top;">CKLISTPATH_LOW CKLISTPATH_MED CKLISTPATH_HIGH</td> <td> <p>These variables define the list of directories to be used by <code>aset</code> to create a <i>checklist</i> file at the <i>low</i>, <i>medium</i>, and <i>high</i> security levels, respectively. Attributes of all the files in the directories defined by these variables will be checked periodically and any changes will be reported by <code>aset</code>. Checks performed on these directories are not recursive. <code>aset</code> only checks directories explicitly listed in these variables and does not check subdirectories of them.</p> </td> </tr> <tr> <td style="vertical-align: top;">YPCHECK</td> <td> <p>This variable is a boolean parameter. It specifies whether <code>aset</code> should extend checking (when applicable) on system tables to their NIS equivalents or not. The value <code>true</code> enables it while the value <code>false</code> disables it.</p> </td> </tr> <tr> <td style="vertical-align: top;">UID_ALIASES</td> <td> <p>This variable specifies an alias file for user ID sharing. Normally, <code>aset</code> warns about multiple user accounts</p> </td> </tr> </table>	TASK	<p>This variable defines the list of tasks that <code>aset</code> will execute the next time it runs. The available tasks are:</p> <table border="0"> <tr> <td><code>tune</code></td> <td>Tighten system files.</td> </tr> <tr> <td><code>usrgrp</code></td> <td>Check user/group.</td> </tr> <tr> <td><code>sysconf</code></td> <td>Check system configuration file.</td> </tr> <tr> <td><code>env</code></td> <td>Check environment.</td> </tr> <tr> <td><code>cklist</code></td> <td>Compare system files checklist.</td> </tr> <tr> <td><code>eeprom</code></td> <td>Check <code>eeprom(1M)</code> parameters.</td> </tr> <tr> <td><code>firewall</code></td> <td>Disable forwarding of IP packets.</td> </tr> </table>	<code>tune</code>	Tighten system files.	<code>usrgrp</code>	Check user/group.	<code>sysconf</code>	Check system configuration file.	<code>env</code>	Check environment.	<code>cklist</code>	Compare system files checklist.	<code>eeprom</code>	Check <code>eeprom(1M)</code> parameters.	<code>firewall</code>	Disable forwarding of IP packets.	CKLISTPATH_LOW CKLISTPATH_MED CKLISTPATH_HIGH	<p>These variables define the list of directories to be used by <code>aset</code> to create a <i>checklist</i> file at the <i>low</i>, <i>medium</i>, and <i>high</i> security levels, respectively. Attributes of all the files in the directories defined by these variables will be checked periodically and any changes will be reported by <code>aset</code>. Checks performed on these directories are not recursive. <code>aset</code> only checks directories explicitly listed in these variables and does not check subdirectories of them.</p>	YPCHECK	<p>This variable is a boolean parameter. It specifies whether <code>aset</code> should extend checking (when applicable) on system tables to their NIS equivalents or not. The value <code>true</code> enables it while the value <code>false</code> disables it.</p>	UID_ALIASES	<p>This variable specifies an alias file for user ID sharing. Normally, <code>aset</code> warns about multiple user accounts</p>
TASK	<p>This variable defines the list of tasks that <code>aset</code> will execute the next time it runs. The available tasks are:</p> <table border="0"> <tr> <td><code>tune</code></td> <td>Tighten system files.</td> </tr> <tr> <td><code>usrgrp</code></td> <td>Check user/group.</td> </tr> <tr> <td><code>sysconf</code></td> <td>Check system configuration file.</td> </tr> <tr> <td><code>env</code></td> <td>Check environment.</td> </tr> <tr> <td><code>cklist</code></td> <td>Compare system files checklist.</td> </tr> <tr> <td><code>eeprom</code></td> <td>Check <code>eeprom(1M)</code> parameters.</td> </tr> <tr> <td><code>firewall</code></td> <td>Disable forwarding of IP packets.</td> </tr> </table>	<code>tune</code>	Tighten system files.	<code>usrgrp</code>	Check user/group.	<code>sysconf</code>	Check system configuration file.	<code>env</code>	Check environment.	<code>cklist</code>	Compare system files checklist.	<code>eeprom</code>	Check <code>eeprom(1M)</code> parameters.	<code>firewall</code>	Disable forwarding of IP packets.								
<code>tune</code>	Tighten system files.																						
<code>usrgrp</code>	Check user/group.																						
<code>sysconf</code>	Check system configuration file.																						
<code>env</code>	Check environment.																						
<code>cklist</code>	Compare system files checklist.																						
<code>eeprom</code>	Check <code>eeprom(1M)</code> parameters.																						
<code>firewall</code>	Disable forwarding of IP packets.																						
CKLISTPATH_LOW CKLISTPATH_MED CKLISTPATH_HIGH	<p>These variables define the list of directories to be used by <code>aset</code> to create a <i>checklist</i> file at the <i>low</i>, <i>medium</i>, and <i>high</i> security levels, respectively. Attributes of all the files in the directories defined by these variables will be checked periodically and any changes will be reported by <code>aset</code>. Checks performed on these directories are not recursive. <code>aset</code> only checks directories explicitly listed in these variables and does not check subdirectories of them.</p>																						
YPCHECK	<p>This variable is a boolean parameter. It specifies whether <code>aset</code> should extend checking (when applicable) on system tables to their NIS equivalents or not. The value <code>true</code> enables it while the value <code>false</code> disables it.</p>																						
UID_ALIASES	<p>This variable specifies an alias file for user ID sharing. Normally, <code>aset</code> warns about multiple user accounts</p>																						

asetenv(4)

sharing the same user ID because it is not advisable for accountability reason. Exceptions can be created using an alias file. User ID sharing allowed by the alias file will not be reported by `aset`. See `asetmasters(4)` for the format of the alias file.

PERIODIC_SCHEDULE

This variable specifies the schedule for periodic execution of ASET. It uses the format of `crontab(1)` entries. Briefly speaking, the variable is assigned a string of the following format:

minutes hours day-of-month month day-of-week

Setting this variable does *not* activate the periodic schedule of ASET. To execute ASET periodically, `aset(1M)` must be run with the `-p` option. See `aset(1M)`. For example, if `PERIODIC_SCHEDULE` is set to the following, and `aset(1M)` was started with the `-p` option, `aset` will run at 12:00 midnight every day:

```
0 0 * * *
```

EXAMPLES

EXAMPLE 1 Sample `asetenv` file showing the settings of the ASET configurable parameters

The following is a sample `asetenv` file, showing the settings of the ASET configurable parameters:

```
CKLISTPATH_LOW=/etc:/
CKLISTPATH_MED=$CHECKLISTPATH_LOW:/usr/bin:/usr/ucb
CKLISTPATH_HIGH=$CHECKLISTPATH_MED:/usr/lib:/usr/sbin
YPCHECK=false
UID_ALIASES=/usr/aset/masters/uid_aliases
PERIODIC_SCHEDULE="0 0 * * *"
TASKS="env sysconf usrgrp"
```

When `aset -p` is run with this file, `aset` is executed at midnight of every day. The `/` and `/etc` directories are checked at the *low* security level; the `/`, `/etc`, `/usr/bin`, and `/usr/ucb` directories are checked at the *medium* security level; and the `/`, `/etc`, `/usr/bin`, `/usr/lib`, and `/usr/sbin` directories are checked at the *high* security level. Checking of NIS system files is disabled. The `/usr/aset/masters/uid_aliases` file specifies the used IDs available for sharing. The `env`, `sysconf`, and `usrgrp` tasks will be performed, checking the environment variables, various system tables, and the local `passwd` and `group` files.

ASET Administrator Manual

NAME	asetmasters, tune.low, tune.med, tune.high, uid_aliases, cklist.low, cklist.med, cklist.high – ASET master files										
SYNOPSIS	<pre> /usr/aset/masters/tune.low /usr/aset/masters/tune.med /usr/aset/masters/tune.high /usr/aset/masters/uid_aliases /usr/aset/masters/cklist.low /usr/aset/masters/cklist.med /usr/aset/masters/cklist.high </pre>										
DESCRIPTION	<p>The <code>/usr/aset/masters</code> directory contains several files used by the Automated Security Enhancement Tool (ASET). <code>/usr/aset</code> is the default operating directory for ASET. An alternative working directory can be specified by the administrators through the <code>aset -d</code> command or the <code>ASETDIR</code> environment variable. See <code>aset(1M)</code>.</p> <p>These files are provided by default to meet the need of most environments. The administrators, however, can edit these files to meet their specific needs. The format and usage of these files are described below.</p> <p>All the master files allow comments and blank lines to improve readability. Comment lines must start with a leading <code>"#"</code> character.</p> <pre> tune.low tune.med tune.high </pre> <p>These files are used by the <code>tune</code> task (see <code>aset(1M)</code>) to restrict the permission settings for system objects. Each file is used by ASET at the security level indicated by the suffix. Each entry in the files is of the form:</p> <pre> <i>pathname mode owner group type</i> </pre> <p>where</p> <table border="0" style="margin-left: 2em;"> <tr> <td><i>pathname</i></td> <td>is the full pathname</td> </tr> <tr> <td><i>mode</i></td> <td>is the permission setting</td> </tr> <tr> <td><i>owner</i></td> <td>is the owner of the object</td> </tr> <tr> <td><i>group</i></td> <td>is the group of the object</td> </tr> <tr> <td><i>type</i></td> <td>is the type of the object It can be <code>symlink</code> for a symbolic link, <code>directory</code> for a directory, or <code>file</code> for everything else.</td> </tr> </table> <p>Regular shell wildcard ("<code>*</code>", "<code>?</code>", ...) characters can be used in the <i>pathname</i> for multiple references. See <code>sh(1)</code>. The <i>mode</i> is a five-digit</p>	<i>pathname</i>	is the full pathname	<i>mode</i>	is the permission setting	<i>owner</i>	is the owner of the object	<i>group</i>	is the group of the object	<i>type</i>	is the type of the object It can be <code>symlink</code> for a symbolic link, <code>directory</code> for a directory, or <code>file</code> for everything else.
<i>pathname</i>	is the full pathname										
<i>mode</i>	is the permission setting										
<i>owner</i>	is the owner of the object										
<i>group</i>	is the group of the object										
<i>type</i>	is the type of the object It can be <code>symlink</code> for a symbolic link, <code>directory</code> for a directory, or <code>file</code> for everything else.										

asetmasters(4)

number that represents the permission setting. Note that this setting represents a least restrictive value. If the current setting is already more restrictive than the specified value, ASET does not loosen the permission settings.

For example, if *mode* is 00777, the permission will not be changed, since it is always less restrictive than the current setting.

Names must be used for *owner* and *group* instead of numeric ID's. ? can be used as a "don't care" character in place of *owner*, *group*, and *type* to prevent ASET from changing the existing values of these parameters.

uid_alias

This file allows user ID's to be shared by multiple user accounts. Normally, ASET discourages such sharing for accountability reason and reports user ID's that are shared. The administrators can, however, define permissible sharing by adding entries to the file. Each entry is of the form:

```
uid=alias1=alias2=alias3= ...
```

where

uid is the shared user id

alias? is the user accounts sharing the user ID

For example, if *sync* and *daemon* share the user ID 1, the corresponding entry is:

```
1=sync=daemon
```

cklist.low

cklist.med

cklist.high

These files are used by the *cklist* task (see *aset(1M)*), and are created the first time the task is run at the *low*, *medium*, and *high* levels. When the *cklist* task is run, it compares the specified directory's contents with the appropriate *cklist.level* file and reports any discrepancies.

EXAMPLES **EXAMPLE 1** Examples of Valid Entries for the *tune.low*, *tune.med*, and *tune.high* Files

The following is an example of valid entries for the *tune.low*, *tune.med*, and *tune.high* files:

```
/bin 00777 root staffsymlink

au(4)

NAME	au – AU audio file format
SYNOPSIS	<pre>#include <audio/au.h></pre>
DESCRIPTION	<p>An AU audio file is composed of three parts: a header, an optional description field, and a contiguous segment of audio data. The header is 24 bytes, and the description field is at least 4 bytes. Therefore, the offset for most AU files is 28 bytes. However, some people store additional data in the AU header.</p> <p>The AU audio structure members and audio data are stored big endian. That is, it starts with the most significant byte, regardless of the native byte order of the machine architecture on which an application may be running. Therefore, multi-byte audio data may require byte reversal for proper playback on different processor architectures. See the macro section for properly reading and writing the AU audio structure members.</p> <p>The AU header is defined by the following structure:</p> <pre>struct au_filehdr { uint32_t au_magic; /* magic number (.snd) */ uint32_t au_offset; /* byte offset to start of audio data */ uint32_t au_data_size; /* data length in bytes */ uint32_t au_encoding; /* data encoding */ uint32_t au_sample_rate; /* samples per second */ uint32_t au_channels; /* number of interleaved channels */ }; typedef struct au_filehdr au_filehdr_t;</pre> <p>The <code>au_magic</code> field always contains the following constant for an AU audio file:</p> <pre>AUDIO_AU_FILE_MAGIC (0x2e736e64) /* ".snd" */</pre> <p>The <code>au_offset</code> field contains the length of the audio file header plus the variable length info field. Consequently, it can be interpreted as the offset from the start of the file to the start of the audio data.</p> <p>The <code>au_data_size</code> field contains the length, in bytes, of the audio data segment. If this length is not known when the header is written, it should be set to <code>AUDIO_AU_UNKNOWN_SIZE</code>, defined as follows:</p> <pre>AUDIO_AU_UNKNOWN_SIZE (~0) /* (unsigned) -1 */</pre> <p>When the <code>au_data_size</code> field contains <code>AUDIO_AU_UNKNOWN_SIZE</code>, the length of the audio data can be determined by subtracting <code>au_offset</code> from the total length of the file.</p> <p>The encoding field contains one of the following enumerated keys:</p> <pre>AUDIO_AU_ENCODING_ULAW /* 8-bit u-law */ AUDIO_AU_ENCODING_LINEAR_8 /* 8-bit linear PCM */ AUDIO_AU_ENCODING_LINEAR_16 /* 16-bit linear PCM */ AUDIO_AU_ENCODING_LINEAR_24 /* 24-bit linear PCM */</pre>

```

AUDIO_AU_ENCODING_LINEAR_32    /* 32-bit linear PCM */
AUDIO_AU_ENCODING_FLOAT        /* Floating point */
AUDIO_AU_ENCODING_DOUBLE       /* Double precision float */
AUDIO_AU_ENCODING_FRAGMENTED   /* Fragmented sample data */
AUDIO_AU_ENCODING_DSP          /* DSP program */
AUDIO_AU_ENCODING_FIXED_8      /* 8-bit fixed point */
AUDIO_AU_ENCODING_FIXED_16     /* 16-bit fixed point */
AUDIO_AU_ENCODING_FIXED_24     /* 24-bit fixed point */
AUDIO_AU_ENCODING_FIXED_32     /* 32-bit fixed point */
AUDIO_AU_ENCODING_EMPHASIS     /* 16-bit linear with emphasis */
AUDIO_AU_ENCODING_COMPRESSED   /* 16-bit linear compressed */
AUDIO_AU_ENCODING_EMP_COMP     /* 16-bit linear with emphasis
                                and compression */
AUDIO_AU_ENCODING_MUSIC_KIT    /* Music kit DSP commands */
AUDIO_AU_ENCODING_ADPCM_G721   /* CCITT G.721 ADPCM */
AUDIO_AU_ENCODING_ADPCM_G722   /* CCITT G.722 ADPCM */
AUDIO_AU_ENCODING_ADPCM_G723_3 /* CCITT G.723.3 ADPCM */
AUDIO_AU_ENCODING_ADPCM_G723_5 /* CCITT G.723.5 ADPCM */
AUDIO_AU_ENCODING_ALAW        /* 8-bit A-law G.711 */

```

All of the linear encoding formats are signed integers centered at zero.

The `au_sample_rate` field contains the audio file's sampling rate in samples per second. Some common sample rates include 8000, 11025, 22050, 44100, and 48000 samples per second.

The `au_channels` field contains the number of interleaved data channels. For monaural data, this value is set to one. For stereo data, this value is set to two. More than two data channels can be interleaved, but such formats are currently unsupported by the Solaris audio driver architecture. For a stereo sound file, the first sample is the left track and the second sample is the right track.

The optional `info` field is a variable length annotation field that can be either text or data. If it is a text description of the sound, then it should be NULL terminated. However, some older files might not be terminated properly. The size of the `info` field is set when the structure is created and cannot be enlarged later.

Macros Accessing all of the AU audio structure members should be done through the supplied `AUDIO_AU_FILE2HOST` and `AUDIO_AU_HOST2FILE` macros. By always using these macros, code will be byte-order independent. See the example below.

EXAMPLES **EXAMPLE 1** Displaying Header Information for a Sound File

The following program reads and displays the header information for an AU sound file. The `AUDIO_AU_FILE2HOST` macro ensures that this information will always be in the proper byte order.

```

void main(void)
{
    au_filehdr_t    hdr;
    au_filehdr_t    local;
    int             fd;

```

au(4)

EXAMPLE 1 Displaying Header Information for a Sound File (Continued)

```
char          *name = "bark.au";

if ((fd = open(name, O_RDONLY)) < 0) {
    printf("can't open file %s\n", name);
    exit(1);
}

(void) read(fd, &hdr, sizeof (hdr));

AUDIO_AU_FILE2HOST(&hdr.au_magic, &local.au_magic);
AUDIO_AU_FILE2HOST(&hdr.au_offset, &local.au_offset);
AUDIO_AU_FILE2HOST(&hdr.au_data_size, &local.au_data_size);
AUDIO_AU_FILE2HOST(&hdr.au_encoding, &local.au_encoding);
AUDIO_AU_FILE2HOST(&hdr.au_sample_rate, &local.au_sample_rate);
AUDIO_AU_FILE2HOST(&hdr.au_channels, &local.au_channels);

printf("Magic = %x\n", local.au_magic);
printf("Offset = %d\n", local.au_offset);
printf("Number of data bytes = %d\n", local.au_data_size);
printf("Sound format = %d\n", local.au_encoding);
printf("Sample rate = %d\n", local.au_sample_rate);
printf("Number of channels = %d\n", local.au_channels);

(void) close(fd);
}
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaudh
Stability Level	Evolving

SEE ALSO attributes(5)

NOTES Some older AU audio files are incorrectly coded with info strings that are not properly NULL-terminated. Thus, applications should always use the `au_offset` value to find the end of the info data and the beginning of the audio data.

NAME	audit_class – audit class definitions						
SYNOPSIS	/etc/security/audit_class						
DESCRIPTION	<p>/etc/security/audit_class is an ASCII system file that stores class definitions. Programs use the <code>getauclassent(3BSM)</code> routines to access this information.</p> <p>The fields for each class entry are separated by colons. Each class entry is a bitmap and is separated from each other by a newline.</p> <p>Each entry in the <code>audit_class</code> file has the form:</p> <pre>mask:name:description</pre> <p>The fields are defined as follows:</p> <table border="0"> <tr> <td><i>mask</i></td> <td>The class mask.</td> </tr> <tr> <td><i>name</i></td> <td>The class name.</td> </tr> <tr> <td><i>description</i></td> <td>The description of the class.</td> </tr> </table> <p>The classes are now user-configurable. Each class is represented as a bit in the class mask which is an unsigned integer. Thus, there are 32 different classes available, plus two meta-classes -- <code>all</code> and <code>no</code>.</p> <p><code>all</code> represents a conjunction of all allowed classes, and is provided as a shorthand method of specifying all classes.</p> <p><code>no</code> is the "invalid" class, and any event mapped solely to this class will not be audited. (Turning auditing on to the <code>all</code> meta class will NOT cause events mapped solely to the <code>no</code> class to be written to the audit trail.)</p>	<i>mask</i>	The class mask.	<i>name</i>	The class name.	<i>description</i>	The description of the class.
<i>mask</i>	The class mask.						
<i>name</i>	The class name.						
<i>description</i>	The description of the class.						
EXAMPLES	<p>EXAMPLE 1 Sample of an <code>audit_class</code> file.</p> <p>Here is a sample of an <code>audit_class</code> file:</p> <pre>0x00000000:no:invalid class 0x00000001:fr:file read 0x00000002:fw:file write 0x00000004:fa:file attribute access 0x00000008:fm:file attribute modify 0x00000010:fc:file create 0x00000020:fd:file delete 0x00000040:cl:file close 0xffffffff:all:all classes</pre>						
FILES	/etc/security/audit_class						
SEE ALSO	bsmconv(1M), getauclassent(3BSM), audit_event(4)						

audit_class(4)

NOTES | It is possible to deliberately turn on the `no` class in the kernel, in which case the audit trail will be flooded with records for the audit event `AUE_NULL`.

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

NAME	audit_control – control information for system audit daemon
SYNOPSIS	/etc/security/audit_control
DESCRIPTION	<p>The <code>audit_control</code> file contains audit control information used by <code>auditd(1M)</code>. Each line consists of a title and a string, separated by a colon. There are no restrictions on the order of lines in the file, although some lines must appear only once. A line beginning with '#' is a comment.</p> <p>Directory definition lines list the directories to be used when creating audit files, in the order in which they are to be used. The format of a directory line is:</p> <pre>dir:directory-name</pre> <p><i>directory-name</i> is where the audit files will be created. Any valid writable directory can be specified.</p> <p>The following configuration is recommended:</p> <pre>/etc/security/audit/server/files</pre> <p>where <i>server</i> is the name of a central machine, since audit files belonging to different servers are usually stored in separate subdirectories of a single audit directory. The naming convention normally has <i>server</i> be a directory on a server machine, and all clients mount <code>/etc/security/audit/server</code> at the same location in their local file systems. If the same server exports several different file systems for auditing, their <i>server</i> names will, of course, be different.</p> <p>There are several other ways for audit data to be arranged: some sites may have needs more in line with storing each host's audit data in separate subdirectories. The audit structure used will depend on each individual site.</p> <p>The audit threshold line specifies the percentage of free space that must be present in the file system containing the current audit file. The format of the threshold line is:</p> <pre>minfree:percentage</pre> <p>where <i>percentage</i> indicates the amount of free space required. If free space falls below this threshold, the audit daemon <code>auditd(1M)</code> invokes the shell script <code>audit_warn(1M)</code>. If no threshold is specified, the default is 0%.</p> <p>The audit flags line specifies the default system audit value. This value is combined with the user audit value read from <code>audit_user(4)</code> to form a user's process preselection mask.</p> <p>The algorithm for obtaining the process preselection mask is as follows: the audit flags from the <code>flags:</code> line in the <code>audit_control</code> file are added to the flags from the</p>

audit_control(4)

always-audit field in the user's entry in the audit_user file. The flags from the never-audit field from the user's entry in the audit_user file are then subtracted from the total:

```
user's process preselection mask =  
  (flags: line + always audit flags) - never audit flags
```

The format of a flags line is:

```
flags:audit-flags
```

where *audit-flags* specifies which event classes are to be audited. The character string representation of *audit-flags* contains a series of flag names, each one identifying a single audit class, separated by commas. A name preceded by '-' means that the class should be audited for failure only; successful attempts are not audited. A name preceded by '+' means that the class should be audited for success only; failing attempts are not audited. Without a prefix, the name indicates that the class is to be audited for both successes and failures. The special string *all* indicates that all events should be audited; *-all* indicates that all failed attempts are to be audited, and *+all* all successful attempts. The prefixes ^, ^-, and ^+ turn off flags specified earlier in the string (^- and ^+ for failing and successful attempts, ^ for both). They are typically used to reset flags.

The non-attributable flags line is similar to the flags line, but this one contain the audit flags that define what classes of events are audited when an action cannot be attributed to a specific user. The format of a *naflags* line is:

```
naflags:audit-flags
```

The flags are separated by commas, with no spaces.

The following table lists the predefined audit classes:

short name	long name	short description
no	no_class	null value for turning off event preselection
fr	file_read	Read of data, open for reading, etc.
fw	file_write	Write of data, open for writing, etc.
fa	file_attr_acc	Access of object attributes: stat, pathconf, etc.
fm	file_attr_mod	Change of object attributes: chown, flock, etc.
fc	file_creation	Creation of object
fd	file_deletion	Deletion of object
cl	file_close	close(2) system call
pc	process	Process operations: fork, exec, exit, etc.
nt	network	Network events: bind, connect, accept, etc.
ip	ipc	System V IPC operations
na	non_attrib	non-attributable events
ad	administrative	administrative actions: mount, exportfs, etc.
lo	login_logout	Login and logout events
ap	application	Application auditing
io	ioctl	ioctl(2) system call
ex	exec	exec(2) system call

```

ot          other          Everything else
all         all           All flags set

```

Note that the classes are configurable, see `audit_class(4)`.

EXAMPLES **EXAMPLE 1** Sample `/etc/security/audit_control` file for the machine `eggplant`.

Here is a sample `/etc/security/audit_control` file for the machine `eggplant`:

```

dir: /etc/security/jedgar/eggplant
dir: /etc/security/jedgar.aux/eggplant
#
# Last-ditch audit file system when jedgar fills up.
#
dir: /etc/security/global/eggplant
minfree: 20
flags: lo,ad,-all,^-fm
naflags: lo,ad

```

This identifies server `jedgar` with two file systems normally used for audit data, another server `global` used only when `jedgar` fills up or breaks, and specifies that the warning script is run when the file systems are 80% filled. It also specifies that all logins, administrative operations are to be audited (whether or not they succeed), and that failures of all types except failures to access object attributes are to be audited.

audit_data(4)

NAME	audit_data – current information on audit daemon
SYNOPSIS	/etc/security/audit_data
DESCRIPTION	<p>The audit_data file contains information about the audit daemon. The file contains the process ID of the audit daemon, and the pathname of the current audit log file. The format of the file is:</p> <pre>pid> : <pathname></pre> <p>Where <i>pid</i> is the process ID for the audit daemon, and <i>pathname</i> is the full pathname for the current audit log file.</p>
EXAMPLES	<p>EXAMPLE 1 A sample audit_data file.</p> <pre>64:/etc/security/audit/server1/19930506081249.19930506230945.bongos</pre>

NOTES	The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See <code>bsmconv(1M)</code> for more information.								

audit.log(4)

NAME	audit.log – audit trail file																								
SYNOPSIS	<pre>#include <bsm/audit.h> #include <bsm/audit_record.h></pre>																								
DESCRIPTION	<p>audit.log files are the depository for audit records stored locally or on an audit server. These files are kept in directories named in the file audit_control(4). They are named to reflect the time they are created and are, when possible, renamed to reflect the time they are closed as well. The name takes the form</p> <pre>yyyymmddhhmmss.not_terminated.hostname</pre> <p>when open or if the auditd(1M) terminated ungracefully, and the form</p> <pre>yyyymmddhhmmss.yyyyymmddhhmmss.hostname</pre> <p>when properly closed. yyyy is the year, mm the month, dd day in the month, hh hour in the day, mm minute in the hour, and ss second in the minute. All fields are of fixed width.</p> <p>The audit.log file begins with a standalone file token and typically ends with one also. The beginning file token records the pathname of the previous audit file, while the ending file token records the pathname of the next audit file. If the file name is NULL the appropriate path was unavailable.</p> <p>The audit.log files contains audit records. Each audit record is made up of <i>audit tokens</i>. Each record contains a header token followed by various data tokens. Depending on the audit policy in place by auditon(2), optional other tokens such as trailers or sequences may be included.</p> <p>The tokens are defined as follows:</p> <p>The file token consists of:</p> <table><tr><td>token ID</td><td>1 byte</td></tr><tr><td>seconds of time</td><td>4 bytes</td></tr><tr><td>milliseconds of time</td><td>4 bytes</td></tr><tr><td>file name length</td><td>2 bytes</td></tr><tr><td>file pathname</td><td>N bytes + 1 terminating NULL byte</td></tr></table> <p>The header token consists of:</p> <table><tr><td>token ID</td><td>1 byte</td></tr><tr><td>record byte count</td><td>4 bytes</td></tr><tr><td>version #</td><td>1 byte [2]</td></tr><tr><td>event type</td><td>2 bytes</td></tr><tr><td>event modifier</td><td>2 bytes</td></tr><tr><td>seconds of time</td><td>4 bytes/8 bytes (32-bit/64-bit value)</td></tr><tr><td>milliseconds of time</td><td>4 bytes/8 bytes (32-bit/64-bit value)</td></tr></table> <p>The expanded header token consists of:</p>	token ID	1 byte	seconds of time	4 bytes	milliseconds of time	4 bytes	file name length	2 bytes	file pathname	N bytes + 1 terminating NULL byte	token ID	1 byte	record byte count	4 bytes	version #	1 byte [2]	event type	2 bytes	event modifier	2 bytes	seconds of time	4 bytes/8 bytes (32-bit/64-bit value)	milliseconds of time	4 bytes/8 bytes (32-bit/64-bit value)
token ID	1 byte																								
seconds of time	4 bytes																								
milliseconds of time	4 bytes																								
file name length	2 bytes																								
file pathname	N bytes + 1 terminating NULL byte																								
token ID	1 byte																								
record byte count	4 bytes																								
version #	1 byte [2]																								
event type	2 bytes																								
event modifier	2 bytes																								
seconds of time	4 bytes/8 bytes (32-bit/64-bit value)																								
milliseconds of time	4 bytes/8 bytes (32-bit/64-bit value)																								

token ID	1 byte
record byte count	4 bytes
version #	1 byte [2]
event type	2 bytes
event modifier	2 bytes
address type/length	4 bytes/16 bytes (IPv4/IPv6 address)
machine address	4 bytes/16 bytes (IPv4/IPv6 address)
seconds of time	4 bytes/8 bytes (32/64-bits)
milliseconds of time	4 bytes/8 bytes (32/64-bits)

The trailer token consists of:

token ID	1 byte
trailer magic number	2 bytes
record byte count	4 bytes

The arbitrary data token is defined:

token ID	1 byte
how to print	1 byte
basic unit	1 byte
unit count	1 byte
data items	(depends on basic unit)

The in_addr token consists of:

token ID	1 byte
internet address	4 bytes

The expanded in_addr token consists of:

token ID	1 byte
IP address type/length	4 bytes/16 bytes (IPv4/IPv6 address)
IP address	16 bytes

The ip token consists of:

token ID	1 byte
version and ihl	1 byte
type of service	1 byte
length	2 bytes
id	2 bytes
offset	2 bytes
ttl	1 byte
protocol	1 byte
checksum	2 bytes
source address	4 bytes
destination address	4 bytes

The expanded ip token consists of:

token ID	1 byte
version and ihl	1 byte
type of service	1 byte
length	2 bytes
id	2 bytes
offset	2 bytes
ttl	1 byte

audit.log(4)

protocol	1 byte
checksum	2 bytes
address type/type	4 bytes
source address	4 bytes/16 bytes (IPv4/IPv6 address)
address type/length	4 bytes/16 bytes (IPv4/IPv6 address)
destination address	4 bytes/16 bytes (IPv4/IPv6 address)

The iptoken consists of:

token ID	1 byte
port IP address	2 bytes

The path token consists of:

token ID	1 byte
path length	2 bytes
path	N bytes + 1 terminating NULL byte

The process token consists of:

token ID	1 byte
audit ID	4 bytes
effective user ID	4 bytes
effective group ID	4 bytes
real user ID	4 bytes
real group ID	4 bytes
process ID	4 bytes
session ID	4 bytes
terminal ID	
port ID	4 bytes/8 bytes (32-bit/64-bit value)
machine address	4 bytes

The expanded process token consists of:

token ID	1 byte
audit ID	4 bytes
effective user ID	4 bytes
effective group ID	4 bytes
real user ID	4 bytes
real group ID	4 bytes
process ID	4 bytes
session ID	4 bytes
terminal ID	
port ID	4 bytes/8 bytes (32-bit/64-bit value)
address type/length	4 bytes/16 bytes (IPv4/IPv6 address)
machine address	16 bytes

The return token consists of:

token ID	1 byte
error number	1 byte
return value	4 bytes/8 bytes (32-bit/64-bit value)

The subject token consists of:

token ID	1 byte
audit ID	4 bytes
effective user ID	4 bytes

effective group ID	4 bytes
real user ID	4 bytes
real group ID	4 bytes
process ID	4 bytes
session ID	4 bytes
terminal ID	
port ID	4 bytes/8 bytes (32-bit/64-bit value)
machine address	4 bytes

The expanded subject token consists of:

token ID	1 byte
audit ID	4 bytes
effective user ID	4 bytes
effective group ID	4 bytes
real user ID	4 bytes
real group ID	4 bytes
process ID	4 bytes
session ID	4 bytes
terminal ID	
port ID	4 bytes/8 bytes (32-bit/64-bit value)
address type/length	4 bytes/16 bytes (IPv4/IPv6 address)
machine address	16 bytes

The System V IPC token consists of:

token ID	1 byte
object ID type	1 byte
object ID	4 bytes

The text token consists of:

token ID	1 byte
text length	2 bytes
text	N bytes + 1 terminating NULL byte

The attribute token consists of:

token ID	1 byte
file access mode	4 bytes
owner user ID	4 bytes
owner group ID	4 bytes
file system ID	4 bytes
node ID	8 bytes
device	4 bytes/8 bytes (32-bit/64-bit)

The groups token consists of:

token ID	1 byte
number groups	2 bytes
group list	N * 4 bytes

The System V IPC permission token consists of:

token ID	1 byte
owner user ID	4 bytes
owner group ID	4 bytes
creator user ID	4 bytes

audit.log(4)

creator group ID	4 bytes
access mode	4 bytes
slot sequence #	4 bytes
key	4 bytes

The arg token consists of:

token ID	1 byte
argument #	1 byte
argument value	4 bytes/8 bytes (32-bit/64-bit value)
text length	2 bytes
text	N bytes + 1 terminating NULL byte

The exec_args token consists of:

token ID	1 byte
count	4 bytes
text	<i>count</i> null-terminated string(s)

The exec_env token consists of:

token ID	1 byte
count	4 bytes
text	<i>count</i> null-terminated string(s)

The exit token consists of:

token ID	1 byte
status	4 bytes
return value	4 bytes

The socket token consists of:

token ID	1 byte
socket type	2 bytes
remote port	2 bytes
remote Internet address	4 bytes

The expanded socket token consists of:

token ID	1 byte
socket domain	2 bytes
socket type	2 bytes
local port	2 bytes
address type/length	4 bytes/16 bytes (IPv4/IPv6 address)
local port	2 bytes
local Internet address	4 bytes/16 bytes (IPv4/IPv6 address)
remote port	2 bytes
remote Internet address	4 bytes/16 bytes (IPv4/IPv6 address)

The seq token consists of:

token ID	1 byte
sequence number	4 bytes

SEE ALSO audit(1M), auditd(1M), bsmconv(1M), audit(2), auditor(2), au_to(3BSM), audit_control(4)

NOTES Each token is generally written using the `au_to(3BSM)` family of function calls.

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

audit_user(4)

NAME	audit_user – per-user auditing data file						
SYNOPSIS	/etc/security/audit_user						
DESCRIPTION	<p>audit_user is an access-restricted database that stores per-user auditing preselection data. The audit_user file can be used with other authorization sources, including the NIS map audit_user.byname and the NIS+ table audit_user. Programs use the getauusernam(3BSM) routines to access this information.</p> <p>The search order for multiple user audit information sources is specified in the /etc/nsswitch.conf file, as described in the nsswitch.conf(4) man page. The lookup follows the search order for passwd(4).</p> <p>The fields for each user entry are separated by colons (:). Each user is separated from the next by a newline. audit_user does not have general read permission.</p> <p>Each entry in the audit_user file has the form:</p> <pre>username:always-audit-flags:never-audit-flags</pre> <p>The fields are defined as follows:</p> <table><tr><td><i>username</i></td><td>The user's login name.</td></tr><tr><td><i>always-audit-flags</i></td><td>Flags specifying event classes to <i>always</i> audit.</td></tr><tr><td><i>never-audit-flags</i></td><td>Flags specifying event classes to <i>never</i> audit.</td></tr></table> <p>For a complete description of the audit flags and how to combine them, see the audit_control(4) man page.</p>	<i>username</i>	The user's login name.	<i>always-audit-flags</i>	Flags specifying event classes to <i>always</i> audit.	<i>never-audit-flags</i>	Flags specifying event classes to <i>never</i> audit.
<i>username</i>	The user's login name.						
<i>always-audit-flags</i>	Flags specifying event classes to <i>always</i> audit.						
<i>never-audit-flags</i>	Flags specifying event classes to <i>never</i> audit.						
EXAMPLES	<p>EXAMPLE 1 Sample audit_user file</p> <pre>other:lo,ad:io,c1 fred:lo,ex,+fc,-fr,-fa:io,c1 ethyl:lo,ex,nt:io,c1</pre>						
FILES	/etc/nsswitch.conf /etc/passwd /etc/security/audit_user						
SEE ALSO	bsmconv(1M), getauusernam(3BSM), audit_control(4), nsswitch.conf(4), passwd(4)						
NOTES	The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.						

NAME	auth_attr – authorization description database
SYNOPSIS	<code>/etc/security/auth_attr</code>
DESCRIPTION	<p><code>/etc/security/auth_attr</code> is a local source for authorization names and descriptions. The <code>auth_attr</code> file can be used with other authorization sources, including the <code>auth_attr</code> NIS map and NIS+ table. Programs use the <code>getauthattr(3SECDB)</code> routines to access this information.</p> <p>The search order for multiple authorization sources is specified in the <code>/etc/nsswitch.conf</code> file, as described in the <code>nsswitch.conf(4)</code> man page.</p> <p>An authorization is a right assigned to users that is checked by certain privileged programs to determine whether users can execute restricted functionality. Each entry in the <code>auth_attr</code> database consists of one line of text containing six fields separated by colons (:). Line continuations using the backslash (\) character are permitted. The format of each entry is:</p> <pre>name:res1:res2:short_desc:long_desc:attr</pre> <p><i>name</i> The name of the authorization. Authorization names are unique strings. Construct authorization names using the following convention:</p> <pre>prefix. or prefix.suffix</pre> <p><i>prefix</i> Everything in the name field up to the final dot (.). Authorizations from Sun Microsystems, Inc. use <code>solaris</code> as a prefix. To avoid name conflicts, all other authorizations should use a prefix that begins with the reverse-order Internet domain name of the organization that creates the authorization (for example, <code>com.xyzcompany</code>). Prefixes can have additional arbitrary components chosen by the authorization's developer, with components separated by dots.</p> <p><i>suffix</i> The final component in the name field. Specifies what is being authorized.</p> <p>When there is no suffix, the name is defined as a heading. Headings are not assigned to users but are constructed for use by applications in their GUIs.</p> <p>When a name ends with the word <code>grant</code>, the entry defines a grant authorization. Grant authorizations are used to support fine-grained delegation. Users with appropriate grant authorizations can delegate some of their authorizations to others.</p>

auth_attr(4)

	To assign an authorization, the user needs to have both the authorization itself and the appropriate grant authorization.
<i>res1</i>	Reserved for future use.
<i>res2</i>	Reserved for future use.
<i>short_desc</i>	A short description or terse name for the authorization. This name should be suitable for displaying in user interfaces, such as in a scrolling list in a GUI.
<i>long_desc</i>	A long description. This field can explain the precise purpose of the authorization, the applications in which it is used, and the type of user that would be interested in using it. The long description can be displayed in the help text of an application.
<i>attr</i>	An optional list of semicolon-separated (;) key-value pairs that describe the attributes of an authorization. Zero or more keys may be specified. The keyword <code>help</code> identifies a help file in HTML. Help files can be read by a web browser using the URL: <code>file:/usr/lib/help/auths/locale/C/index.html</code>

EXAMPLES

EXAMPLE 1 Constructing a name

In the following example, the name has a prefix (`solaris.`) followed by a suffix (`printer`):

```
solaris.printer
```

EXAMPLE 2 Defining a heading

Because the name field ends with a dot, the following entry defines a heading:

```
solaris.hostmgr.:::Computers & Networks::help=HostMgrHeader.html
```

EXAMPLE 3 Assigning separate authorizations to set user attributes

In this example, a heading entry is followed by other associated authorization entries. The entries below the heading provide separate authorizations for setting user attributes. The *attr* field for each entry, including the heading entry, assigns a help file. The application that uses the `help` key requires the value to equal the name of a file ending in `.htm` or `.html`:

```
solaris.usermgr.:::Users, Groups & Email Aliases::help=UserMgrHeader.html
solaris.usermgr.pswd.:::Change User Passwords::help=UserMgrPswd.html
solaris.usermgr.write.:::Add, Modify & Delete::help=UserMgrWrite.html
```

EXAMPLE 4 Assigning a grant authorization

This example assigns to an administrator the following authorizations:

EXAMPLE 4 Assigning a grant authorization (Continued)

```
solaris.printmgr.grant
solaris.printmgr.admin
solaris.printmgr.nobanner
solaris.login.enable
```

With the above authorizations, the administrator can assign to others the `solaris.printmgr.admin` and `solaris.printmgr.nobanner` authorizations, but not the `solaris.login.enable` authorization. If the administrator has both the grant authorization, `solaris.printmgr.grant`, and the wildcard authorization, `solaris.printmgr.*`, the administrator can grant to others any of the printer authorizations. See `user_attr(4)` for more information about how wildcards can be used to assign multiple authorizations whose names begin with the same components.

EXAMPLE 5 Authorizing the ability to assign other authorizations

The following entry defines an authorization that grants the ability to assign any authorization created with a `solaris` prefix, when the administrator also has either the specific authorization being granted or a matching wildcard entry:

```
solaris.grant:::Grant All Rights::help=PriAdmin.html
```

EXAMPLE 6 Consulting the local authorization file ahead of the NIS table

With the following entry from `/etc/nsswitch.conf`, the local `auth_attr` file is consulted before the NIS table:

```
auth_attr:files nisplus
```

FILES `/etc/nsswitch.conf`
`/etc/user_attr`
`/etc/security/auth_attr`

NOTES When deciding which authorization source to use (see **DESCRIPTION**), keep in mind that NIS+ provides stronger authentication than NIS.

Because the list of legal keys is likely to expand, any code that parses this database must be written to ignore unknown key-value pairs without error. When any new keywords are created, the names should be prefixed with a unique string, such as the company's stock symbol, to avoid potential naming conflicts.

Each application has its own requirements for whether the help value must be a relative pathname ending with a filename or the name of a file. The only known requirement is for the name of a file.

auth_attr(4)

The following characters are used in describing the database format and must be escaped with a backslash if used as data: colon (:), semicolon (;), equals (=), and backslash (\).

getuserattr(3SECDB), exec_attr(4), nsswitch.conf(4), user_attr(4)

NAME	bootparams – boot parameter data base
SYNOPSIS	<code>/etc/bootparams</code>
DESCRIPTION	<p>The <code>bootparams</code> file contains a list of client entries that diskless clients use for booting. Diskless booting clients retrieve this information by issuing requests to a server running the <code>rpc.bootparamd(1M)</code> program. The <code>bootparams</code> file may be used in conjunction with or in place of other sources for the <code>bootparams</code> information. See <code>nsswitch.conf(4)</code>.</p> <p>For each client the file contains an entry with the client's name and a list of boot parameter values for that client. Each entry has the form:</p> <pre><i>clientname keyword=value...</i></pre> <p>The first item of each entry is the host name of the diskless client. You can use the asterisk (*) character as a "wildcard" in place of the client name in a single entry. A wildcard entry applies to all clients for which there is not an entry that specifically names them.</p> <p>In a given entry, the host name or asterisk is followed by one or more whitespace characters and a series of keyword—value pairs separated by whitespace characters. There must not be any whitespace within a keyword—value pair.</p> <p>Each keyword—value pair has the syntax:</p> <pre><i>keyword=value</i></pre> <p>The preceding form breaks out further as:</p> <pre><i>keyword=server:value</i>Where <i>server</i> can be null and <i>value</i> can be a pathname.</pre> <p>An example that includes a server is:</p> <pre>client1 root=server1:/export/client1/root</pre> <p>An example where <i>server</i> is null is:</p> <pre>client1 rootopts=:vers2</pre> <p>A minor variation of the <i>keyword=value</i> syntax is used for the <code>domain</code> keyword. Unlike the forms shown above, this syntax does not use a colon. For example:</p> <pre>client1 domain=bldg1.workco.com</pre> <p>Entries can span multiple lines. Use the backslash (\) character as the last character of a line to continue the entry to the following line. For multiple-line entries, you can</p>

bootparams(4)

split a line only in places where whitespace is allowed. For example, you can use a backslash to split the following entry between the end of the path (*root*) and the keyword domain:

```
client1 root=server1:/export/client1/root domain=bldg1.workco.com
```

In entries that specify a server, *server* is the name of the server that will provide the file or filesystem to the diskless client and *value* is the pathname of the exported file or filesystem on that server.

In entries that use the *domain* keyword, the domain name specified must be the client's domain name. The algorithm for determining a client's domain name is to first check for a *domain* keyword in the client-specific entry and then in "wildcard" entry. If none is found, the server's domain name is used.

For the JumpStart installation of machines that do not have video displays, use the *term* keyword to identify the terminal type of the boot server. Terminal types are listed in `/usr/share/lib/terminfo` (see `terminfo(4)`).

An entry with the *ns* keyword associates a server (a name server) with, instead of a pathname, a specific name service (NIS+, NIS, or none) and, if that server is not on a local subnet, the netmask needed to reach it. For example:

```
ns=hoot:nisplus(255.255.255.0)
```

An *ns* entry forces `sysidtool(1M)` to use the specified name service. By default, `sysidtool` uses NIS+ in preference to NIS if it can find an NIS+ server for the system's domain on the subnet. An *ns* entry might be necessary if you are trying to set up a hands-off installation, or if the name server is on a different subnet, which is common with NIS+.

If an *ns* keyword is not used, `sysidtool` uses broadcast to attempt to bind to either a NIS+ or NIS server. If a name server is not on the local subnet, which is possible for NIS+, the bind will fail, automatic configuration of the name service will fail, and an interactive screen is displayed, prompting the user to specify the name service.

The *ns* keyword can be set in `add_install_client` or by Host Manager.

EXAMPLES **EXAMPLE 1** Example bootparams Entry

Here is an example of an entry in the `bootparams` file:

```
client1 root=server1:/export/client1/root rootopts=:vers=2 \  
domain=bldg1.workco.com  
client2 root=server2:/export/client2/root ns=:nis  
client3 root=server2:/export/client3/root ns=watson:  
client4 root=server2:/export/client4/root \  
ns=mach:nisplus(255.255.255.0)
```

EXAMPLE 1 Example bootparams Entry (Continued)

EXAMPLE 2 Entry for JumpStart

The following is an example of an entry that might be used for the JumpStart installation of diskless clients that do not have displays.

```
mozart root=haydn:/export/install/sparc/os/latest/Solaris 8/boot \  
install=haydn:/export/install/sparc/os/8.1/latest boottype=:in \  
install_config=haydn:/usr/local/share/lib/jump-net \  
ns=otis:nisplus(255.255.255.0) term=:xterms domain=eu.cte.work.com
```

FILES /etc/bootparams

SEE ALSO rpc.bootparamd(1M), sysidtool(1M), nsswitch.conf(4)

NOTES Solaris diskless clients use the keywords `root` and `rootopts` to look up the pathname for the root filesystem and the mount options for the root filesystem (see `mount_ufs(1M)`, respectively. These are the only keywords meaningful for diskless booting clients.

cdtoc(4)

NAME	cdtoc – CD-ROM table of contents file
DESCRIPTION	<p>The table of contents file, <code>.cdtoc</code>, is an ASCII file that describes the contents of a CD-ROM or other software distribution media. It resides in the top-level directory of the file system on a slice of a CD-ROM. It is independent of file system format, that is, the file system on the slice can be either UFS or HSFs.</p> <p>Each entry in the <code>.cdtoc</code> file is a line that establishes the value of a parameter in the following form:</p> <p><i>PARAM=value</i></p> <p>Blank lines and comments (lines preceded by a pound-sign, "#") are also allowed in the file. Parameters are grouped by product, with the beginning of a product defined by a line of the form:</p> <p><i>PRODNAME=value</i></p> <p>Each product is expected to consist of one or more software packages that are stored together in a subdirectory on the distribution media. There can be any number of products described within the file. There is no required order in which the parameters must be specified, except that the parameters must be grouped by product and the <i>PRODNAME</i> parameter must appear first in the list of parameters for each product specified. Each parameter is described below. All of the parameters are required for each product.</p> <p><i>PRODNAME</i> The full name of the product. This must be unique within the <code>.cdtoc</code> file and is preferably unique across all possible products. This value may contain white space. The length of this value is limited to 256 ASCII characters; other restrictions may apply (see below).</p> <p><i>PRODVERS</i> The version of the product. The value can contain any combination of letters, numbers, or other characters. This value may contain white space. The length of this value is limited to 256 ASCII characters; other restrictions may apply (see below).</p> <p><i>PRODDIR</i> The name of the top-level directory containing the product. This name should be relative to the top-level directory of the distribution media, for example, <code>Solaris_2.6/Product</code>. The number of path components in the name is limited only by the system's maximum path name length, which is 1024 ASCII characters. Any single component is limited to 256 ASCII characters. This value cannot contain white space.</p>

The lengths of the values of *PRODDIR* and *PRODDIR* are further constrained by the fact that the initial install programs and `swmtool(1M)` concatenate these values to produce the full product name. `swmtool(1M)` concatenates the two values (inserting a space) to produce the name displayed in its software selection menu, for example, Solaris 2.6. For unbundled products the combined length of the values of *PRODDIR* and *PRODDIR* must not exceed 256 ASCII characters.

When you install OS services with Solstice Host Manager, directories for diskless clients and Autoclient systems are created by constructing names derived from a concatenation of the values of *PRODDIR*, *PRODDIR*, and client architecture, for example, `/export/exec/Solaris_2.x_sparc.all/usr/platform`. The length of the component containing the product name and version must not exceed 256 ASCII characters. Thus, for products corresponding to bundled OS releases (for example, Solaris 2.4), the values of *PRODDIR* and *PRODDIR* are effectively restricted to lengths much less than 256.

The initial install programs and `swmtool(1M)` use the value of the *PRODDIR* macro in the `.cdtoc` file to indicate where packages can be found.

EXAMPLES

EXAMPLE 1 Sample of `.cdtoc` file.

Here is a sample `.cdtoc` file:

```
#
# .cdtoc file -- Online product family CD
#
PRODDIR=Online DiskSuite
PRODDIR=2.0
PRODDIR=Online_DiskSuite_2.0
#
PRODDIR=Online Backup
PRODDIR=2.0
PRODDIR=Online_Backup_2.0
```

This example corresponds to the following directory layout on a CD-ROM partition:

```
/.cdtoc
/Online_DiskSuite_2.0
  ./SUNWmddr.c
  ./SUNWmddr.m
  ./SUNWmddu
/Online_Backup_2.0
  ./SUNWhsm
```

The bundled release of Solaris 2.6 includes the following `.cdtoc` file:

```
PRODDIR=Solaris
PRODDIR=2.6
PRODDIR=Solaris_2.6/Product
```

This file corresponds to the following directory layout on slice 0 of the Solaris 2.6 product CD:

cdtoc(4)

EXAMPLE 1 Sample of .cdtoc file. *(Continued)*

```
/.cdtoc
/Solaris_2.6/Product
./SUNWaccr
./SUNWaccu
./SUNWadmap
.
.
.
./SUNWutool
```

SEE ALSO swmtool(1M), clustertoc(4), packagetoc(4), pkginfo(4)

NAME	clustertoc – cluster table of contents description file
DESCRIPTION	<p>The cluster table of contents file, <code>.clustertoc</code>, is an ASCII file that describes a hierarchical view of a software product. A <code>.clustertoc</code> file is required for the base OS product. The file resides in the top-level directory containing the product.</p> <p>The hierarchy described by <code>.clustertoc</code> can be of arbitrary depth, although the initial system installation programs assume that it has three levels. The hierarchy is described bottom-up, with the packages described in <code>.packagetoc</code> at the lowest layer. The next layer is the <i>cluster</i> layer which collects packages into functional units. The highest layer is the <i>meta-cluster</i> layer which collects packages and clusters together into typical configurations.</p> <p>The hierarchy exists to facilitate the selection or deselection of software for installation at varying levels of granularity. Interacting at the package level gives the finest level of control over what software is to be installed.</p> <p>Each entry in the <code>.clustertoc</code> file is a line that establishes the value of a parameter in the following form:</p> <pre>PARAM=value</pre> <p>A line starting with a pound-sign, "#", is considered a comment and is ignored.</p> <p>Parameters are grouped by cluster or meta-cluster. The start of a cluster description is defined by a line of the form:</p> <pre>CLUSTER=value</pre> <p>The start of a meta-cluster description is defined by a line of the form:</p> <pre>METACLUSTER=value</pre> <p>There is no order implied or assumed for specifying the parameters for a (meta-)cluster with the exception of the <code>CLUSTER</code> or <code>METACLUSTER</code> parameter, which must appear first and the <code>END</code> parameter which must appear last.</p> <p>The following parameters are mandatory:</p> <p>CLUSTER</p> <p>The cluster identifier (for example, <code>SUNWCacc</code>). The identifier specified must be unique within the package and cluster identifier namespace defined by a product's <code>.packagetoc</code> and <code>.clustertoc</code> files. The identifiers used are subject to the same constraints as those for package identifiers. These constraints are (from <code>pkginfo(4)</code>):</p> <p>All characters in the abbreviation must be alphanumeric and the first may not be numeric. The abbreviation is limited to a maximum length of nine characters. <code>install</code>, <code>new</code>, and <code>all</code> are reserved abbreviations.</p>

clustertoc(4)

A cluster must be described before another cluster or meta-cluster may refer to it.

DESC

An informative textual description of the (meta-)cluster's contents. The length of the description supplied may not exceed 256 characters. The text should contain no newlines.

METACLUSTER

The metacluster identifier (for example, `SUNWCprog`). The identifier specified must be unique within the package and cluster identifier namespace defined by a product's `.packagetoc` and `.clustertoc` files. The identifiers used are subject to the same constraints as those for package identifiers. These constraints are (from `pkginfo(4)`):

All characters in the abbreviation must be alphanumeric and the first may not be numeric. The abbreviation is limited to a maximum length of nine characters. `install`, `new`, and `all` are reserved abbreviations.

Meta-clusters can not contain references to other meta-clusters.

NAME

The full name of the (meta-)cluster. The length of the name string supplied may not exceed 256 characters.

SUNW_CSRMEMBER

Indicates that the package or cluster is a part of the (meta-) cluster currently being described. The value specified is the identifier of the package or cluster. There may be an arbitrary number of `SUNW_CSRMEMBER` parameters per (meta-)cluster.

VENDOR

The name of the (meta-)cluster's vendor. The length of the vendor string supplied may not exceed 256 characters.

VERSION

The version of the (meta-)cluster. The length of the version string supplied may not exceed 256 characters.

The following parameters are optional:

DEFAULT

Specifies which metacluster within a `.clustertoc` file should be selected or installed by default. Only one metacluster can be the default.

HIDDEN

Specifies whether a metacluster should be hidden by applications. A hidden metacluster cannot be `DEFAULT`.

REQUIRED

Specifies which metacluster is required. A required metacluster implies that all of its cluster and package members are not de-selectable (must be installed).

SUNW_CSRMBRIFF

Indicates that the package is to be included dynamically in the (meta-)cluster currently being described. The value of this parameter must follow the following format:

```
SUNW_CSRMBRIFF=(test test_arc)package
```

This line is converted into a SUNW_CSRMEMBER entry at media installation time if the test provided matches the platform on which the media is being installed. There may be zero or more SUNW_CSRMBRIFF parameters per (meta-)cluster.

```
SUNW_CSRMBRIFF=(test value)package
```

where the *test* is either the builtin test of "platform" or a shell script which returns shell true (0) or shell false (1) depending on the tests being performed in the script. *value* is passed to the test as the first argument and can be used to create a script that tests for multiple hardware objects. Finally *package* is the package that is included in the final .clustertoc file as a SUNW_CSRMEMBER. See parse_dynamic_clustertoc(1M) for more information about the scripts.

EXAMPLES**EXAMPLE 1 A Cluster Description**

The following is an example of a cluster description in a .clustertoc file.

```
CLUSTER=SUNWCacc
NAME=System Accounting
DESC=System accounting utilities
VENDOR=Sun Microsystems, Inc.
VERSION=7.2
SUNW_CSRMEMBER=SUNWaccr
SUNW_CSRMEMBER=SUNWaccu
END
```

EXAMPLE 2 A Meta-cluster Description

The following is an example of a meta-cluster description in a .clustertoc file.

```
METACLUSTER=SUNWCreq
NAME=Core System Support
DESC=A pre-defined software configuration consisting of the minimum
required software for a standalone, non-networked workstation.
VENDOR=Sun Microsystems, Inc.
VERSION=2.x
SUNW_CSRMEMBER=SUNWadmr
SUNW_CSRMEMBER=SUNWcar
SUNW_CSRMEMBER=SUNWCcs
SUNW_CSRMEMBER=SUNWCcg6
SUNW_CSRMEMBER=SUNWCdfb
SUNW_CSRMEMBER=SUNWkvm
SUNW_CSRMEMBER=SUNWCnis
SUNW_CSRMEMBER=SUNWowdv
SUNW_CSRMEMBER=SUNWter
END
```

clustertoc(4)

EXAMPLE 3 A Meta-cluster Description With a Dynamic Cluster Entry

The following is an example of a meta-cluster description with a dynamic cluster entry as indicated by the use of the `SUNW_CSRMBRIF` parameter entries.

```
METACLUSTER=SUNWCprog
NAME=Developer System Support
DESC=A pre-defined software configuration consisting of the
typical software used by software developers.
VENDOR=Sun Microsystems, Inc.
VERSION=2.5
SUNW_CSRMEMBER=SUNWCadm
SUNW_CSRMBRIF=(smcc.dctoc tcx)SUNWCtcx
SUNW_CSRMBRIF=(smcc.dctoc leo)SUNWCleo
SUNW_CSRMBRIF=(smcc.dctoc sx)SUNWCsx
. . .
END
```

SEE ALSO `parse_dynamic_clustertoc(1M)`, `cdtoc(4)`, `order(4)`, `packagetoc(4)`, `pkginfo(4)`

NOTES The current implementation of the initial system installation programs depend on the `.clustertoc` describing three required meta-clusters for the base OS product:

<code>SUNWC</code>	Contains all of the software packages in the OS distribution.
<code>SUNWC</code> <code>user</code>	Contains the typical software packages for an end-user of the OS distribution.
<code>SUNWC</code> <code>req</code>	Contains the bare-minimum packages required to boot and configure the OS to the point of running a multi-user shell.

NAME	compver – compatible versions file
DESCRIPTION	<p>compver is an ASCII file used to specify previous versions of the associated package which are upward compatible. It is created by a package developer.</p> <p>Each line of the file specifies a previous version of the associated package with which the current version is backward compatible.</p> <p>Since some packages may require installation of a specific version of another software package, compatibility information is extremely crucial. Consider, for example, a package called "A" which requires version "1.0" of application "B" as a prerequisite for installation. If the customer installing "A" has a newer version of "B" (version 1.3), the compver file for "B" must indicate that "1.3" is compatible with version "1.0" in order for the customer to install package "A".</p>
EXAMPLES	<p>EXAMPLE 1 Sample compver file.</p> <p>A sample compver file is shown below:</p> <pre>Version 1.3 Version 1.0</pre>
SEE ALSO	<p>pkginfo(4)</p> <p><i>Application Packaging Developer's Guide</i></p>
NOTES	<p>The comparison of the version string disregards white space and tabs. It is performed on a word-by-word basis. Thus, "Version 1.3" and "Version 1.3" would be considered the same.</p> <p>The entries in the compver file must match the values assigned to the VERSION parameter in the pkginfo(4) files.</p>

copyright(4)

NAME	copyright – copyright information file
DESCRIPTION	<code>copyright</code> is an ASCII file used to provide a copyright notice for a package. The text may be in any format. The full file contents (including comment lines) are displayed on the terminal at the time of package installation.
SEE ALSO	<i>Application Packaging Developer's Guide</i>

NAME	core – process core file
DESCRIPTION	<p>The operating system writes out a core file for a process when the process is terminated due to the receipt of certain signals. A core file is a disk copy of the contents of the process address space at the time the process received the signal, along with additional information about the state of the process. This information can be consumed by a debugger. Core files can also be generated by applying the <code>gcore(1)</code> utility to a running process.</p> <p>Typically, core files are produced following abnormal termination of a process resulting from a bug in the corresponding application. Whatever the cause, the core file itself provides invaluable information to the programmer or support engineer to aid in diagnosing the problem. The core file can be inspected using a debugger such as <code>dbx(1)</code> or <code>mdb(1)</code> or by applying one of the <code>proc(1)</code> tools.</p> <p>The operating system attempts to create up to two core files for each abnormally terminating process, using a global core file name pattern and a per-process core file name pattern. These patterns are expanded to determine the pathname of the resulting core files, and can be configured by <code>coreadm(1M)</code>. By default, the global core file pattern is disabled and not used, and the per-process core file pattern is set to <code>core</code>. Therefore, by default, the operating system attempts to create a core file named <code>core</code> in the process's current working directory.</p> <p>A process will terminate and produce a core file whenever it receives one of the signals whose default disposition is to cause a core dump. The list of signals that result in generating a core file is shown in <code>signal(3HEAD)</code>. Therefore, a process might not produce a core file if it has blocked or modified the behavior of the corresponding signal. Additionally, no core dump can be created under the following conditions:</p> <ul style="list-style-type: none"> ■ If normal file and directory access permissions prevent the creation or modification of the per-process core file pathname by the current process user and group ID. This test does not apply to the global core file pathname because the global core file is always written as the super-user. ■ If the core file pattern expands to a pathname that contains intermediate directory components that do not exist. For example, if the global pattern is set to <code>/var/core/%n/core.%p</code>, and no directory <code>/var/core/'uname -n'</code> has been created, no global core files will be produced. ■ If the destination directory is part of a filesystem that is mounted read-only. ■ If the resource limit <code>RLIMIT_CORE</code> has been set to 0 for the process. Refer to <code>setrlimit(2)</code> and <code>ulimit(1)</code> for more information on resource limits. ■ If the core file name already exists in the destination directory and is not a regular file (that is, is a symlink, block or character special-file, and so forth). ■ If the kernel cannot open the destination file <code>O_EXCL</code>, which can occur if same file is being created by another process simultaneously. ■ If the process's effective user ID is different from its real user ID or if its effective group ID is different from its real group ID. Similarly, <code>set-user-ID</code> and <code>set-group-ID</code>

core(4)

programs do not produce core files as this could potentially compromise system security. These processes can be explicitly granted permission to produce core files using `coreadm(1M)`, at the risk of exposing secure information.

The core file contains all the process information pertinent to debugging: contents of hardware registers, process status, and process data. The format of a core file is object file specific.

For ELF executable programs (see `a.out(4)`), the core file generated is also an ELF file, containing ELF program and file headers. The `e_type` field in the file header has type `ET_CORE`. The program header contains an entry for every segment that was part of the process address space, including shared library segments. The contents of the writable segments are also part of the core image.

The program header of an ELF core file also contains entries for two NOTE segments, each containing several note entries as described below. The note entry header and core file note type (`n_type`) definitions are contained in `<sys/elf.h>`. The first NOTE segment exists for binary compatibility with old programs that deal with core files. It contains structures defined in `<sys/old_procfs.h>`. New programs should recognize and skip this NOTE segment, advancing instead to the new NOTE segment. The old NOTE segment will be deleted from core files in a future release.

The old NOTE segment contains the following entries. Each has entry name "CORE" and presents the contents of a system structure:

<code>prpsinfo_t</code>	<code>n_type</code> : <code>NT_PRPSINFO</code> . This entry contains information of interest to the <code>ps(1)</code> command, such as process status, CPU usage, "nice" value, controlling terminal, user-ID, process-ID, the name of the executable, and so forth. The <code>prpsinfo_t</code> structure is defined in <code><sys/old_procfs.h></code> .
<code>char array</code>	<code>n_type</code> : <code>NT_PLATFORM</code> . This entry contains a string describing the specific model of the hardware platform on which this core file was created. This information is the same as provided by <code>sysinfo(2)</code> when invoked with the command <code>SI_PLATFORM</code> .
<code>auxv_t array</code>	<code>n_type</code> : <code>NT_AUXV</code> . This entry contains the array of <code>auxv_t</code> structures that was passed by the operating system as startup information to the dynamic linker. Auxiliary vector information is defined in <code><sys/auxv.h></code> .

Following these entries, for each *light-weight process* (LWP) in the process, the old NOTE segment contains an entry with a `prstatus_t` structure, plus other optionally-present entries describing the LWP, as follows:

<code>prstatus_t</code>	<code>n_type</code> : <code>NT_PRSTATUS</code> . This structure contains things of interest to a debugger from the operating system,
-------------------------	--------------------------------------------------------------------------------------------------------------------------------------

	such as the general registers, signal dispositions, state, reason for stopping, process-ID, and so forth. The <code>prstatus_t</code> structure is defined in <code><sys/old_procfs.h></code> .
<code>prfpregset_t</code>	<code>n_type</code> : <code>NT_PRFPREG</code> . This entry is present only if the LWP used the floating-point hardware. It contains the floating-point registers. The <code>prfpregset_t</code> structure is defined in <code><sys/procfs_isa.h></code> .
<code>gwindows_t</code>	<code>n_type</code> : <code>NT_GWINDOWS</code> . This entry is present only on a SPARC machine and only if the system was unable to flush all of the register windows to the stack. It contains all of the unspilled register windows. The <code>gwindows_t</code> structure is defined in <code><sys/regset.h></code> .
<code>prxregset_t</code>	<code>n_type</code> : <code>NT_PRXREG</code> . This entry is present only if the machine has extra register state associated with it. It contains the extra register state. The <code>prxregset_t</code> structure is defined in <code><sys/procfs_isa.h></code> .
The new NOTE segment contains the following entries. Each has entry name "CORE" and presents the contents of a system structure:	
<code>psinfo_t</code>	<code>n_type</code> : <code>NT_PSINFO</code> . This structure contains information of interest to the <code>ps(1)</code> command, such as process status, CPU usage, "nice" value, controlling terminal, user-ID, process-ID, the name of the executable, and so forth. The <code>psinfo_t</code> structure is defined in <code><sys/procfs.h></code> .
<code>pstatus_t</code>	<code>n_type</code> : <code>NT_PSTATUS</code> . This structure contains things of interest to a debugger from the operating system, such as pending signals, state, process-ID, and so forth. The <code>pstatus_t</code> structure is defined in <code><sys/procfs.h></code> .
char array	<code>n_type</code> : <code>NT_PLATFORM</code> . This entry contains a string describing the specific model of the hardware platform on which this core file was created. This information is the same as provided by <code>sysinfo(2)</code> when invoked with the command <code>SI_PLATFORM</code> .
<code>auxv_t</code> array	<code>n_type</code> : <code>NT_AUXV</code> . This entry contains the array of <code>auxv_t</code> structures that was passed by the operating system as startup information to the dynamic linker. Auxiliary vector information is defined in <code><sys/auxv.h></code> .

core(4)

`struct utsname` `n_type`: `NT_UTSNAME`. This structure contains the system information that would have been returned to the process if it had performed a `uname(2)` system call prior to dumping core. The `utsname` structure is defined in `<sys/utsname.h>`.

`prcred_t` `n_type`: `NT_PRCRED`. This structure contains the process credentials, including the real, saved, and effective user and group IDs. The `prcred_t` structure is defined in `<sys/procfs.h>`. Following the structure is an optional array of supplementary group IDs. The total number of supplementary group IDs is given by the `pr_ngroups` member of the `prcred_t` structure, and the structure includes space for one supplementary group. If `pr_ngroups` is greater than 1, there will be `pr_ngroups - 1` `gid_t` items following the structure; otherwise, there will be no additional data.

Following these entries, for each LWP in the process, the new NOTE segment contains an entry with an `lwpsinfo_t` structure plus an entry with an `lwpstatus_t` structure, plus other optionally-present entries describing the LWP, as follows:

`lwpsinfo_t` `n_type`: `NT_LWPSINFO`. This structure contains information of interest to the `ps(1)` command, such as LWP status, CPU usage, "nice" value, LWP-ID, and so forth. The `lwpsinfo_t` structure is defined in `<sys/procfs.h>`.

`lwpstatus_t` `n_type`: `NT_LWPSTATUS`. This structure contains things of interest to a debugger from the operating system, such as the general registers, the floating point registers, state, reason for stopping, LWP-ID, and so forth. The `lwpstatus_t` structure is defined in `<sys/procfs.h>`.

`gwindows_t` `n_type`: `NT_GWINDOWS`. This entry is present only on a SPARC machine and only if the system was unable to flush all of the register windows to the stack. It contains all of the unspilled register windows. The `gwindows_t` structure is defined in `<sys/regset.h>`.

`prxregset_t` `n_type`: `NT_PRXREG`. This entry is present only if the machine has extra register state associated with it. It contains the extra register state. The `prxregset_t` structure is defined in `<sys/procfs_isa.h>`.

`asrset_t` `n_type`: `NT_ASRS`. This entry is present only on a SPARC V9 machine and only if the process is a 64-bit process. It contains the ancillary state registers for the LWP. The `asrset_t` structure is defined in `<sys/regset.h>`.

core(4)

The size of the core file created by a process may be controlled by the user (see `getrlimit(2)`).

ANSI C Programmer's Guide

dacf.conf(4)

NAME dacf.conf – device auto-configuration configuration file

SYNOPSIS /etc/dacf.conf

DESCRIPTION The kernel uses the dacf.conf file to automatically configure hot plugged devices. Because the dacf.conf file contains important kernel state information, it should not be modified.

The format of the /etc/dacf.conf file is not public and might change in versions of the Solaris operating environment that are not compatible with Solaris 8.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr

SEE ALSO attributes(5)

NOTES This document does not constitute an API. The /etc/dacf.conf file might not exist or might contain different contents or interpretations in versions of the Solaris operating environment that are not compatible with Solaris 8. The existence of this notice does not imply that any other documentation lacking this notice constitutes an API.

NAME	defaultdomain – specify host's domain name
SYNOPSIS	/etc/defaultdomain
DESCRIPTION	<p>The file /etc/defaultdomain determines a host's domain name for direct use by the NIS and NIS+ name services. The defaultdomain file is read at boot time and its contents used by the domainname(1M) command. Because of its use by domainname, defaultdomain is also used by the LDAP service (see ldap(1)). Under certain, narrow circumstances (see resolv.conf(4)), because domainname uses defaultdomain, a DNS client can use the contents of defaultdomain.</p> <p>The contents of defaultdomain consists of a single line containing a host's domain name.</p>
SEE ALSO	nis+(1), uname(1), ldapclient(1M), nisclient(1M), ypbind(1M), ypinit(1M), resolv.conf(4)
NOTES	The defaultdomain file is created and modified by Solaris installation and configuration scripts. Only users knowledgeable of name service configuration should edit the file.

default_fs(4)

NAME	default_fs, fs – specify the default file system type for local or remote file systems						
DESCRIPTION	<p>When file system administration commands have both specific and generic components (for example, <code>fsck(1M)</code>), the file system type must be specified. If it is not explicitly specified using the <code>-F <i>FSType</i></code> command line option, the generic command looks in <code>/etc/vfstab</code> in order to determine the file system type, using the supplied raw or block device or mount point. If the file system type can not be determined by searching <code>/etc/vfstab</code>, the command will use the default file system type specified in either <code>/etc/default/fs</code> or <code>/etc/dfs/fstypes</code>, depending on whether the file system is local or remote.</p> <p>The default local file system type is specified in <code>/etc/default/fs</code> by a line of the form <code>LOCAL=<i>fstype</i></code> (for example, <code>LOCAL=ufs</code>). The default remote file system type is determined by the first entry in the <code>/etc/dfs/fstypes</code> file.</p> <p>File system administration commands will determine whether the file system is local or remote by examining the specified device name. If the device name starts with <code>"/</code> (slash), it is considered to be local; otherwise it is remote.</p> <p>The default file system types can be changed by editing the default files with a text editor.</p>						
FILES	<table><tr><td><code>/etc/vfstab</code></td><td>list of default parameters for each file system</td></tr><tr><td><code>/etc/default/fs</code></td><td>the default local file system type</td></tr><tr><td><code>/etc/dfs/fstypes</code></td><td>the default remote file system type</td></tr></table>	<code>/etc/vfstab</code>	list of default parameters for each file system	<code>/etc/default/fs</code>	the default local file system type	<code>/etc/dfs/fstypes</code>	the default remote file system type
<code>/etc/vfstab</code>	list of default parameters for each file system						
<code>/etc/default/fs</code>	the default local file system type						
<code>/etc/dfs/fstypes</code>	the default remote file system type						
SEE ALSO	<code>fsck(1M)</code> , <code>fstypes(4)</code> , <code>vfstab(4)</code>						

NAME	defaultrouter – configuration file for default router(s)	
SYNOPSIS	<code>/etc/defaultrouter</code>	
DESCRIPTION	<p>The <code>/etc/defaultrouter</code> file specifies a IPv4 host's default router(s).</p> <p>The format of the file is as follows:</p> <pre>IP_address ...</pre> <p>The <code>/etc/defaultrouter</code> file can contain the IP addresses or hostnames of one or more default routers, with each entry on its own line. If you use hostnames, each hostname must also be listed in the local <code>/etc/hosts</code> file, because no name services are running at the time that <code>defaultrouter</code> is read.</p> <p>Lines beginning with the “#” character are treated as comments.</p> <p>The default routes listed in this file replace those added by the kernel during diskless booting. An empty <code>/etc/defaultrouter</code> file will cause the default route added by the kernel to be deleted.</p> <p>Use of a default route, whether received from a DHCP server or from <code>/etc/defaultrouter</code>, prevents a machine from acting as an IPv4 router, even if that machine does not have an <code>/etc/notrouter</code> file.</p>	
FILES	<code>/etc/defaultrouter</code>	Configuration file containing the hostnames or IP addresses of one or more default routers.
SEE ALSO	<code>in.rdisc(1M)</code> , <code>in.routed(1M)</code> , <code>hosts(4)</code>	

depend(4)

NAME	depend – software dependencies file								
DESCRIPTION	<p>depend is an ASCII file used to specify information concerning software dependencies for a particular package. The file is created by a software developer.</p> <p>Each entry in the depend file describes a single software package. The instance of the package is described after the entry line by giving the package architecture and/or version. The format of each entry and subsequent instance definition is:</p> <pre>type pkg name (arch)version (arch)version ...</pre> <p>The fields are:</p> <table><tr><td>type</td><td>Defines the dependency type. Must be one of the following characters:</td></tr><tr><td>P</td><td>Indicates a prerequisite for installation; for example, the referenced package or versions must be installed.</td></tr><tr><td>I</td><td>Implies that the existence of the indicated package or version is incompatible.</td></tr><tr><td>R</td><td>Indicates a reverse dependency. Instead of defining the package's own dependencies, this designates that another package depends on this one. This type should be used only when an old package does not have a depend file, but relies on the newer package nonetheless. Therefore, the present package should not be removed if the designated old package is still on the system since, if it is removed, the old package will no longer work.</td></tr></table> <p><i>pkg</i> Indicates the package abbreviation.</p> <p><i>name</i> Specifies the full package name.</p> <p><i>(arch)version</i> Specifies a particular instance of the software. A version name cannot begin with a left parenthesis. The instance specifications, both <i>(arch)</i> and <i>version</i>, are completely optional, but each <i>(arch)version</i> pair must begin on a new line that begins with white space. A null version set equates to any version of the indicated package.</p>	type	Defines the dependency type. Must be one of the following characters:	P	Indicates a prerequisite for installation; for example, the referenced package or versions must be installed.	I	Implies that the existence of the indicated package or version is incompatible.	R	Indicates a reverse dependency. Instead of defining the package's own dependencies, this designates that another package depends on this one. This type should be used only when an old package does not have a depend file, but relies on the newer package nonetheless. Therefore, the present package should not be removed if the designated old package is still on the system since, if it is removed, the old package will no longer work.
type	Defines the dependency type. Must be one of the following characters:								
P	Indicates a prerequisite for installation; for example, the referenced package or versions must be installed.								
I	Implies that the existence of the indicated package or version is incompatible.								
R	Indicates a reverse dependency. Instead of defining the package's own dependencies, this designates that another package depends on this one. This type should be used only when an old package does not have a depend file, but relies on the newer package nonetheless. Therefore, the present package should not be removed if the designated old package is still on the system since, if it is removed, the old package will no longer work.								
EXAMPLES	<p>EXAMPLE 1 Sample of depend file</p> <p>Here are the contents of a sample depend file, for the SUNWftpr (FTP Server) package, stored in /var/sadm/pkg/SUNWftpr/install:</p> <pre>P SUNWcar Core Architecture, (Root) P SUNWkvm Core Architecture, (Kvm)</pre>

device_allocate(4)

NAME	device_allocate – device_allocate file														
SYNOPSIS	<i>/etc/security/device_allocate</i>														
DESCRIPTION	<p>The <i>device_allocate</i> file contains mandatory access control information about each physical device. Each device is represented by a one line entry of the form:</p> <pre><i>device-name;device-type;reserved;reserved;auths;device-exec</i></pre> <p>where</p> <table><tr><td><i>device-name</i></td><td>This is an arbitrary ASCII string naming the physical device. This field contains no embedded white space or non-printable characters.</td></tr><tr><td><i>device-type</i></td><td>This is an arbitrary ASCII string naming the generic device type. This field identifies and groups together devices of like type. This field contains no embedded white space or non-printable characters.</td></tr><tr><td>reserved</td><td>This field is reserved for future use.</td></tr><tr><td>reserved</td><td>This field is reserved for future use.</td></tr><tr><td><i>auths</i></td><td>This field contains a comma-separated list of authorizations required to allocate the device, or asterisk (*) to indicate that the device is <i>not</i> allocatable, or an '@' symbol to indicate that no explicit authorization is needed to allocate the device.</td></tr><tr><td></td><td>The default authorization is <i>solaris.device.allocate</i>. See <i>auths(1)</i></td></tr><tr><td><i>device-exec</i></td><td>This is the physical device's data purge program to be run any time the device is acted on by <i>allocate(1)</i>. This is to ensure that all usable data is purged from the physical device before it is reused. This field contains the filename of a program in <i>/etc/security/lib</i> or the full pathname of a cleanup script provided by the system administrator.</td></tr></table> <p>The <i>device_allocate</i> file is an ASCII file that resides in the <i>/etc/security</i> directory.</p> <p>Lines in <i>device_allocate</i> can end with a '\ ' to continue an entry on the next line.</p> <p>Comments may also be included. A '#' makes a comment of all further text until the next NEWLINE not immediately preceded by a '\ '.</p> <p>White space is allowed in any field.</p>	<i>device-name</i>	This is an arbitrary ASCII string naming the physical device. This field contains no embedded white space or non-printable characters.	<i>device-type</i>	This is an arbitrary ASCII string naming the generic device type. This field identifies and groups together devices of like type. This field contains no embedded white space or non-printable characters.	reserved	This field is reserved for future use.	reserved	This field is reserved for future use.	<i>auths</i>	This field contains a comma-separated list of authorizations required to allocate the device, or asterisk (*) to indicate that the device is <i>not</i> allocatable, or an '@' symbol to indicate that no explicit authorization is needed to allocate the device.		The default authorization is <i>solaris.device.allocate</i> . See <i>auths(1)</i>	<i>device-exec</i>	This is the physical device's data purge program to be run any time the device is acted on by <i>allocate(1)</i> . This is to ensure that all usable data is purged from the physical device before it is reused. This field contains the filename of a program in <i>/etc/security/lib</i> or the full pathname of a cleanup script provided by the system administrator.
<i>device-name</i>	This is an arbitrary ASCII string naming the physical device. This field contains no embedded white space or non-printable characters.														
<i>device-type</i>	This is an arbitrary ASCII string naming the generic device type. This field identifies and groups together devices of like type. This field contains no embedded white space or non-printable characters.														
reserved	This field is reserved for future use.														
reserved	This field is reserved for future use.														
<i>auths</i>	This field contains a comma-separated list of authorizations required to allocate the device, or asterisk (*) to indicate that the device is <i>not</i> allocatable, or an '@' symbol to indicate that no explicit authorization is needed to allocate the device.														
	The default authorization is <i>solaris.device.allocate</i> . See <i>auths(1)</i>														
<i>device-exec</i>	This is the physical device's data purge program to be run any time the device is acted on by <i>allocate(1)</i> . This is to ensure that all usable data is purged from the physical device before it is reused. This field contains the filename of a program in <i>/etc/security/lib</i> or the full pathname of a cleanup script provided by the system administrator.														

The `device_allocate` file must be created by the system administrator before device allocation is enabled.

The `device_allocate` file is owned by root, with a group of sys, and a mode of 0644.

EXAMPLES **EXAMPLE 1** Declaring an allocatable device

Declare that physical device `st0` is a type `st`. `st` is allocatable, and the script used to clean the device after running `deallocate(1)` is named `/etc/security/lib/st_clean`.

```
# scsi tape
st0;\
  st;\
  reserved;\
  reserved;\
  solaris.device.allocate;\
  /etc/security/lib/st_clean;\
```

EXAMPLE 2 Declaring an allocatable device with authorizations

Declare that physical device `fd0` is of type `fd`. `fd` is allocatable by users with the `solaris.device.allocate` authorization, and the script used to clean the device after running `deallocate(1)` is named `/etc/security/lib/fd_clean`.

```
# floppy drive
fd0;\
  fd;\
  reserved;\
  reserved;\
  & \
  /etc/security/lib/fd_clean;\
```

Notice that making a device allocatable means that you need to allocate and deallocate it to use it (with `allocate(1)` and `deallocate(1)`). If a device is not allocatable, there will be an asterisk (*) in the `auths` field, and no one can use the device.

FILES `/etc/security/device_allocate` Contains list of allocatable devices

SEE ALSO `auths(1)`, `allocate(1)`, `bsmconv(1M)`, `deallocate(1)`, `list_devices(1)`, `auth_attr(4)`

NOTES The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

device_maps(4)

NAME	device_maps – device_maps file
SYNOPSIS	/etc/security/device_maps
DESCRIPTION	<p>The <code>device_maps</code> file contains access control information about each physical device. Each device is represented by a one line entry of the form:</p> <pre><i>device-name</i> : <i>device-type</i> : <i>device-list</i> :</pre> <p>where</p> <p><i>device-name</i> This is an arbitrary ASCII string naming the physical device. This field contains no embedded white space or non-printable characters.</p> <p><i>device-type</i> This is an arbitrary ASCII string naming the generic device type. This field identifies and groups together devices of like type. This field contains no embedded white space or non-printable characters.</p> <p><i>device-list</i> This is a list of the device special files associated with the physical device. This field contains valid device special file path names separated by white space.</p> <p>The <code>device_maps</code> file is an ASCII file that resides in the <code>/etc/security</code> directory.</p> <p>Lines in <code>device_maps</code> can end with a <code>'\'</code> to continue an entry on the next line.</p> <p>Comments may also be included. A <code>'#'</code> makes a comment of all further text until the next NEWLINE not immediately preceded by a <code>'\'</code>.</p> <p>Leading and trailing blanks are allowed in any of the fields.</p> <p>The <code>device_maps</code> file must be created by the system administrator before device allocation is enabled.</p> <p>This file is owned by root, with a group of <code>sys</code>, and a mode of 0644.</p>
EXAMPLES	<p>EXAMPLE 1 A sample <code>device_maps</code> file</p> <pre># scsi tape st1:\ rmt:\ /dev/rst21 /dev/nrst21 /dev/rst5 /dev/nrst5 /dev/rst13 \ /dev/nrst13 /dev/rst29 /dev/nrst29 /dev/rmt/1l /dev/rmt/1m \ /dev/rmt/1 /dev/rmt/1h /dev/rmt/1u /dev/rmt/1ln /dev/rmt/1mn \ /dev/rmt/1n /dev/rmt/1hn /dev/rmt/1un /dev/rmt/1b /dev/rmt/1bn:\</pre>
FILES	/etc/security/device_maps
SEE ALSO	allocate(1), bsmconv(1M), deallocate(1), dminfo(1M), list_devices(1)

NOTES | The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

dfstab(4)

NAME	dfstab – file containing commands for sharing resources across a network
DESCRIPTION	<p>dfstab resides in directory <code>/etc/dfs</code> and contains commands for sharing resources across a network. <code>dfstab</code> gives a system administrator a uniform method of controlling the automatic sharing of local resources.</p> <p>Each line of the <code>dfstab</code> file consists of a <code>share(1M)</code> command. The <code>dfstab</code> file can be read by the shell to share all resources. System administrators can also prepare their own shell scripts to execute particular lines from <code>dfstab</code>.</p> <p>The contents of <code>dfstab</code> are executed automatically when the system enters run-level 3.</p>
SEE ALSO	<code>share(1M)</code> , <code>shareall(1M)</code>

NAME	dhcp_inittab – information repository for DHCP options						
DESCRIPTION	<p>The <code>/etc/dhcp/inittab</code> file contains information about the Dynamic Host Configuration Protocol (DHCP) options, which are network configuration parameters passed from DHCP servers to DHCP clients when a client machine uses DHCP. Since many DHCP-related commands must parse and understand these DHCP options, this file serves as a central location where information about these options may be obtained.</p> <p>The DHCP <code>inittab</code> file provides three general pieces of information:</p> <ul style="list-style-type: none"> ■ A mnemonic alias, or symbol name, for each option number. For instance, option 12 is aliased to the name <code>Hostname</code>. This is useful for DHCP-related programs that require human interaction, such as <code>dhcpinfo(1)</code>. ■ Information about the syntax for each option. This includes information such as the type of the value, for example, whether it is a 16-bit integer or an IP address. ■ The policy for what options are visible to which DHCP-related programs. <p>The <code>dhcp_inittab</code> file can only be changed upon system upgrade. Only additions of <code>SITE</code> options (or changes to same) will be preserved during upgrade.</p> <p>The <code>VENDOR</code> options defined here are intended for use by the Solaris DHCP client and DHCP management tools. The <code>SUNW</code> vendor space is owned by Sun, and changes are likely during upgrade. If you need to configure the Solaris DHCP server to support the vendor options of a different client, see <code>dhctab(4)</code> for details.</p> <p>Each DHCP option belongs to a certain category, which roughly defines the scope of the option; for instance, an option may only be understood by certain hosts within a given site, or it may be globally understood by all DHCP clients and servers. The following categories are defined; the category names are not case-sensitive:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">STANDARD</td> <td>All client and server DHCP implementations agree on the semantics. These are administered by the Internet Assigned Numbers Authority (IANA). These options are numbered from 1 to 127.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">SITE</td> <td>Within a specific site, all client and server implementations agree on the semantics. However, at another site the type and meaning of the option may be quite different. These options are numbered from 128 to 254.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">VENDOR</td> <td>Each vendor may define 254 options unique to that vendor. The vendor is identified within a DHCP packet by the "Vendor Class" option, number 60. An option with a specific numeric identifier belonging to one vendor will, in general, have a type and semantics different from that of a different vendor. Vendor options are "super-encapsulated" into the vendor field number 43, as</td> </tr> </table>	STANDARD	All client and server DHCP implementations agree on the semantics. These are administered by the Internet Assigned Numbers Authority (IANA). These options are numbered from 1 to 127.	SITE	Within a specific site, all client and server implementations agree on the semantics. However, at another site the type and meaning of the option may be quite different. These options are numbered from 128 to 254.	VENDOR	Each vendor may define 254 options unique to that vendor. The vendor is identified within a DHCP packet by the "Vendor Class" option, number 60. An option with a specific numeric identifier belonging to one vendor will, in general, have a type and semantics different from that of a different vendor. Vendor options are "super-encapsulated" into the vendor field number 43, as
STANDARD	All client and server DHCP implementations agree on the semantics. These are administered by the Internet Assigned Numbers Authority (IANA). These options are numbered from 1 to 127.						
SITE	Within a specific site, all client and server implementations agree on the semantics. However, at another site the type and meaning of the option may be quite different. These options are numbered from 128 to 254.						
VENDOR	Each vendor may define 254 options unique to that vendor. The vendor is identified within a DHCP packet by the "Vendor Class" option, number 60. An option with a specific numeric identifier belonging to one vendor will, in general, have a type and semantics different from that of a different vendor. Vendor options are "super-encapsulated" into the vendor field number 43, as						

dhcp_inittab(4)

DHCP inittab Format

	defined in <i>RFC 2132</i> . The <code>dhcp_inittab</code> file only contains Sun vendor options. Define non-Sun vendor options in the <code>dhcptab</code> file.
FIELD	This category allows the fixed fields within a DHCP packet to be aliased to a mnemonic name for use with <code>dhcpinfo(1)</code> .
INTERNAL	This category is internal to the Solaris DHCP implementation and will not be further defined.

Data entries are written one per line and have seven fields; each entry provides information for one option. Each field is separated by a comma, except for the first and second, which are separated by whitespace (as defined in `isspace(3C)`). An entry cannot be continued onto another line. Blank lines and those whose first non-whitespace character is '#' are ignored.

The fields, in order, are:

- **Mnemonic Identifier**

The Mnemonic Identifier is a user-friendly alias for the option number; it is not case sensitive. This field must be per-category unique and should be unique across all categories. The option names in the `STANDARD`, `SITE`, and `VENDOR` spaces should not overlap, or the behavior will be undefined. See `Mnemonic Identifiers for Options` section of this man page for descriptions of the option names.
- **Category (scope)**

The Category field is one of `STANDARD`, `SITE`, `VENDOR`, `FIELD`, or `INTERNAL` and identifies the scope in which the option falls.
- **Option Number**

The Option Number is the number of this option when it is in a DHCP packet. This field should be per-category unique and the `STANDARD` and `SITE` fields should not have overlapping code fields or the behavior is undefined.
- **Data Type**

Data Type is one of the following values, which are not case sensitive:

<code>Ascii</code>	A printable character string
<code>Bool</code>	Has no value. Scope limited to category limited to <code>INTERNAL</code> . Presence of an option of this type within a Solaris configuration file represents <code>TRUE</code> , absence represents <code>FALSE</code> .
<code>Octet</code>	An array of bytes
<code>Unumber8</code>	An 8-bit unsigned integer
<code>Snumber8</code>	An 8-bit signed integer
<code>Unumber16</code>	A 16-bit unsigned integer
<code>Snumber16</code>	A 16-bit signed integer

Unumber32	A 32-bit unsigned integer
Snumber32	A 32-bit signed integer
Unumber64	A 64-bit unsigned integer
Snumber64	A 64-bit signed integer
Ip	An IP address

The data type field describes an indivisible unit of the option payload, using one of the values listed above.

- Granularity

The Granularity field describes how many "indivisible units" in the option payload make up a whole value or item for this option. The value must be greater than zero (0) for any data type other than Bool, in which case it must be zero (0).

- Maximum Number Of Items

This value specifies the maximum items of Granularity which are permissible in a definition using this symbol. For example, there can only be one IP address specified for a subnet mask, so the Maximum number of items in this case is one (1). A Maximum value of zero (0) means that a variable number of items is permitted.

- Visibility

The Visibility field specifies which DHCP-related programs make use of this information, and should always be defined as "sdmi" for newly added options.

Mnemonic Identifiers for Options

The following table maps the mnemonic identifiers used in Solaris DHCP to *RFC 2132* options:

<i>Symbol</i>	<i>Code</i>	<i>Description</i>
Subnet	1	Subnet Mask, dotted Internet address (IP).
UTCoffst	2	Coordinated Universal time offset (seconds).
Router	3	List of Routers, IP.
Timeserv	4	List of RFC-868 servers, IP.
IEN116ns	5	List of IEN 116 name servers, IP.
DNSserv	6	List of DNS name servers, IP.
Logserv	7	List of MIT-LCS UDP log servers, IP.
Cookie	8	List of RFC-865 cookie servers, IP.
Lprserv	9	List of RFC-1179 line printer servers, IP.
Impress	10	List of Imagen Impress servers, IP.

dhcp_inittab(4)

<i>Symbol</i>	<i>Code</i>	<i>Description</i>
Resource	11	List of RFC-887 resource location servers, IP.
Hostname	12	Client's hostname, value from hosts database.
Bootsize	13	Number of 512 octet blocks in boot image, NUMBER.
Dumpfile	14	Path where core image should be dumped, ASCII.
DNSdmain	15	DNS domain name, ASCII.
Swapserv	16	Client's swap server, IP.
Rootpath	17	Client's Root path, ASCII.
ExtendP	18	Extensions path, ASCII.
IpFwdF	19	IP Forwarding Enable/Disable, NUMBER.
NLrouteF	20	Non-local Source Routing, NUMBER.
PFilter	21	Policy Filter, IP.
MaxIpSiz	22	Maximum datagram Reassembly Size, NUMBER.
IpTTL	23	Default IP Time to Live, (1=<x<=255), NUMBER.
PathTO	24	RFC-1191 Path MTU Aging Timeout, NUMBER.
PathTbl	25	RFC-1191 Path MTU Plateau Table, NUMBER.
MTU	26	Interface MTU, x>=68, NUMBER.
SameMtuF	27	All Subnets are Local, NUMBER.
Broadcst	28	Broadcast Address, IP.
MaskDscF	29	Perform Mask Discovery, NUMBER.
MaskSupF	30	Mask Supplier, NUMBER.
RDiscvyF	31	Perform Router Discovery, NUMBER.
RSolicitS	32	Router Solicitation Address, IP.
StaticRt	33	Static Route, Double IP (network router).
TrailerF	34	Trailer Encapsulation, NUMBER.
ArpTimeO	35	ARP Cache Time out, NUMBER.
EthEncap	36	Ethernet Encapsulation, NUMBER.
TcpTTL	37	TCP Default Time to Live, NUMBER.
TcpKaInt	38	TCP Keepalive Interval, NUMBER.

<i>Symbol</i>	<i>Code</i>	<i>Description</i>
TcpKaGbF	39	TCP Keepalive Garbage, NUMBER.
NISdmain	40	NIS Domain name, ASCII.
NISservs	41	List of NIS servers, IP.
NTPservs	42	List of NTP servers, IP.
NetBNms	44	List of NetBIOS Name servers, IP.
NetBDsts	45	List of NetBIOS Distribution servers, IP.
NetBNdT	46	NetBIOS Node type (1=B-node, 2=P, 4=M, 8=H)
NetBScop	47	NetBIOS scope, ASCII.
XFontSrv	48	List of X Window Font servers, IP.
XDispMgr	49	List of X Window Display managers, IP.
LeaseTim	51	Lease Time Policy, (-1 = PERM), NUMBER.
Message	56	Message to be displayed on client, ASCII.
T1Time	58	Renewal (T1) time, NUMBER.
T2Time	59	Rebinding (T2) time, NUMBER.
NW_dmain	62	NetWare/IP Domain Name, ASCII.
NWIPOpts	63	NetWare/IP Options, OCTET (unknown type).
NIS+dom	64	NIS+ Domain name, ASCII.
NIS+serv	65	NIS+ servers, IP.
TFTPsrVN	66	TFTP server hostname, ASCII.
OptBootF	67	Optional Bootfile path, ASCII.
MblIPAgT	68	Mobile IP Home Agent, IP.
SMTPserv	69	Simple Mail Transport Protocol Server, IP.
POP3serv	70	Post Office Protocol (POP3) Server, IP.
NNTPserv	71	Network News Transport Proto. (NNTP) Server, IP.
WWWservs	72	Default WorldWideWeb Server, IP.
Fingersv	73	Default Finger Server, IP.
IRCservs	74	Internet Relay Chat Server, IP.
STservs	75	StreetTalk Server, IP.

dhcp_inittab(4)

<i>Symbol</i>	<i>Code</i>	<i>Description</i>
STDAservs	76	StreetTalk Directory Assist. Server, IP.
UserClas	77	User class information, ASCII.
SLP_DA	78	Directory agent, OCTET.
SLP_SS	79	Service scope, OCTET.
AgentOpt	82	Agent circuit ID, OCTET.
FQDN	89	Fully Qualified Domain Name, OCTET.
PXEarch	93	Client system architecture, NUMBER.
PXEnii	94	Client Network Device Interface, OCTET.
PXEcId	97	UUID/GUID-based client identifier, OCTET.
BootFile	N/A	File to Boot, ASCII.
BootPath	N/A	Boot path prefix to apply to client's requested boot file, ASCII.
BootSrvA	N/A	Boot Server, IP.
BootSrvN	N/A	Boot Server Hostname, ASCII.
EchoVC	N/A	Echo Vendor Class Identifier Flag, (Present=TRUE)
LeaseNeg	N/A	Lease is Negotiable Flag, (Present=TRUE)
Include	N/A	Include listed macro values in this macro.

EXAMPLES **EXAMPLE 1** Altering the DHCP inittab File

In general, the DHCP `inittab` file should only be altered to add `SITE` options. If other options are added, they will not be automatically carried forward when the system is upgraded. For instance:

```
ipPairs    SITE, 132, IP, 2, 0, sdmi
```

describes an option named `ipPairs`, that is in the `SITE` category. That is, it is defined by each individual site, and is option code 132, which is of type IP Address, consisting of a potentially infinite number of pairs of IP addresses.

dhcp_network(4)

NAME	dhcp_network – DHCP network tables
DESCRIPTION	<p>The Dynamic Host Configuration Protocol (DHCP) network tables are used to map the client identifiers of DHCP clients to IP addresses and the associated configuration parameters of that address. One DHCP network table exists for each network served by the DHCP server, and each table is named using the network's IP address. There is no table or file with the name dhcp_network.</p> <p>The DHCP network tables can exist as ASCII text files, binary text files, or NIS+ tables, depending on the data store used. Since the format of the file could change, the preferred method of managing the DHCP network tables is through the use of dhcpmgr(1M) or the pntadm(1M) command.</p> <p>The format of the records in a DHCP network table depends on the data store used to maintain the table. However, an entry in a DHCP network table must contain the following fields:</p> <p>Client_ID The client identifier field, Client_ID, is an ASCII hexadecimal representation of the unique octet string value of the DHCP Client Identifier Option (code 61) which identifies a DHCP client. In the absence of the DHCP Client Identifier Option, the DHCP client is identified using the form given below for BOOTP clients. The number of characters in this field must be an even number, with a maximum length of 64 characters. Valid characters are 0 - 9 and A-F. Entries with values of 00 are freely available for dynamic allocation to requesting clients. BOOTP clients are identified by the concatenation of the network's hardware type (as defined by RFC 1340, titled "Assigned Numbers") and the client's hardware address. For example, the following BOOTP client has a hardware type of '01' (10mb ethernet) and a hardware address of 8:0:20:11:12:b7, so its client identifier would be: 010800201112B7</p> <p>Flags The Flags field is a decimal value, the bit fields of which can have a combination of the following values:</p> <ul style="list-style-type: none">1 (PERMANENT) Evaluation of the Lease field is turned off (lease is permanent). If this bit is not set, Evaluation of the Lease field is enabled and the Lease is DYNAMIC.2 (MANUAL) This entry has a manual client ID binding (cannot be reclaimed by DHCP server). Client will not be allocated another address.4 (UNUSABLE) When set, this value means that either through ICMP echo or client DECLINE, this address has been found to be unusable.

dhcp_network(4)

Can also be used by the network administrator to *prevent* a certain client from booting, if used in conjunction with the MANUAL flag.

8 (BOOTP)

This entry is reserved for allocation to BOOTP clients only.

Client_IP	The Client_IP field holds the IP address for this entry. This value must be unique in the database.
Server_IP	This field holds the IP address of the DHCP server which <i>owns</i> this client IP address, and thus is responsible for initial allocation to a requesting client.
Lease	This numeric field holds the entry's absolute lease expiration time, and is in seconds since January 1, 1970. It can be decimal, or hexadecimal (if 0x prefixes number). The special value -1 is used to denote a permanent lease.
Macro	This ASCII text field contains the dhcptab macro name used to look up this entry's configuration parameters in the dhcptab(4) database.
Comment	This ASCII text field contains an optional comment.

TREATISE ON LEASES

This section describes how the DHCP/BOOTP server calculates a client's configuration lease using information contained in the dhcptab(4) and DHCP network tables. The server consults the LeaseTim and LeaseNeg symbols in the dhcptab, and the Flags and Lease fields of the chosen IP address record in the DHCP network table.

The server first examines the Flags field for the identified DHCP network table record. If the PERMANENT flag is on, then the client's lease is considered permanent.

If the PERMANENT flag is not on, the server checks if the client's lease as represented by the Lease field in the network table record has expired. If the lease is not expired, the server checks if the client has requested a new lease. If the LeaseNeg symbol has not been included in the client's dhcptab parameters, then the client's requested lease extension is ignored, and the lease is set to be the time remaining as shown by the Lease field. If the LeaseNeg symbol *has* been included, then the server will extend the client's lease to the value it requested if this requested lease is less than or equal to the current time plus the value of the client's LeaseTim dhcptab parameter.

If the client's requested lease is greater than policy allows (value of LeaseTim), then the client is given a lease equal to the current time plus the value of LeaseTim. If LeaseTim is not set, then the default LeaseTim value is one hour.

For more information about the dhcptab symbols, see dhcptab(4).

Solaris DHCP Service Developer's Guide

System Administration Guide: IP Services

Reynolds, J. and J. Postel, *Assigned Numbers*, STD 2, RFC 1340, USC/Information Sciences Institute, July 1992.

NAME	dhcpcsvc.conf – file containing service configuration parameters for the DHCP service
DESCRIPTION	<p>The <code>dhcpcsvc.conf</code> file resides in directory <code>/etc/inet</code> and contains parameters for specifying Dynamic Host Configuration Protocol (DHCP) service configuration settings, including the type and location of DHCP data store used.</p> <p>The description of the <code>dhcpcsvc.conf</code> file in this man page is informational only. The preferred method of setting or modifying values within the <code>dhcpcsvc.conf</code> file is by using <code>dhcpcconfig(1M)</code> or the <code>dhcpcmgr(1M)</code> utility. Do not edit the <code>dhcpcsvc.conf</code> file.</p> <p>The <code>dhcpcsvc.conf</code> file format is ASCII; comment lines begin with the crosshatch (#) character. Parameters consist of a keyword followed by an equals (=) sign followed by the parameter value, of the form:</p> <p><i>Keyword=Value</i></p> <p>The following <i>Keyword</i> and <i>Value</i> parameters are supported:</p> <p>BOOTP_COMPAT String. <code>automatic</code> or <code>manual</code>. Enables support of BOOTP clients. Default is <code>no BOOTP</code>. Value selects BOOTP address allocation method. <code>automatic</code> to support all BOOTP clients, <code>manual</code> to support only registered BOOTP clients. <code>server mode only</code> parameter.</p> <p>CACHE_TIMEOUT Integer. Number of seconds the server will cache data from data store. Used to improve performance. Default is 10 seconds. <code>server mode only</code> parameter.</p> <p>CONVER Integer. Container version. Used by DHCP administrative tools to identify which version of the public module is being used to administer the data store. <code>CONVER</code> should <i>not</i> be changed manually.</p> <p>DAEMON_ENABLED <code>TRUE/FALSE</code>. If <code>TRUE</code>, the DHCP daemon can be run. If <code>FALSE</code>, DHCP daemon process will exit immediately if the daemon is started. Default is <code>TRUE</code>. Generic parameter.</p> <p>HOSTS_DOMAIN String. Defines name service domain that DHCP administration tools use when managing the hosts table. Valid only when <code>HOSTS_RESOURCE</code> is set to <code>nisplus</code> or <code>dns</code>.</p> <p>HOSTS_RESOURCE String. Defines what name service resource should be used by the DHCP administration tools when managing the hosts table. Current valid values are <code>files</code>, <code>nisplus</code>, and <code>dns</code>.</p> <p>ICMP_VERIFY <code>TRUE/FALSE</code>. Toggles ICMP echo verification of IP addresses. Default is <code>TRUE</code>. <code>server mode only</code> parameter.</p>

INTERFACES

String. Comma-separated list of interface names to listen to. Generic parameter.

LOGGING_FACILITY

Integer. Local facility number (0–7 inclusive) to log DHCP events to. Default is not to log transactions. Generic parameter.

OFFER_CACHE_TIMEOUT

Integer. Number of seconds before OFFER cache timeouts occur. Default is 10 seconds. *server* mode only parameter.

PATH

Path to DHCP data tables within the data store specified by the RESOURCE parameter. The value of the PATH keyword is specific to the RESOURCE.

RELAY_DESTINATIONS

String. Comma-separated list of host names and/or IP addresses of relay destinations. *relay* mode only parameter.

RELAY_HOPS

Integer. Max number of BOOTP relay hops before packet is dropped. Default is 4. Generic parameter.

RESCAN_INTERVAL

Integer. Number of minutes between automatic dhcptab rescans. Default is not to do rescans. *server* mode only parameter.

RESOURCE

Data store resource used. Use this parameter to name the public module. See the PATH keyword in `dhcp_modules(5)`.

RESOURCE_CONFIG

String. This might be used for a database account name or other authentication or authorization parameters required by a particular data store. `dhcp_modules(5)`.

Providers can use the RESOURCE_CONFIG known as `configure` by specifying an optional service provider layer API function:

```
int configure(const char *configp);
```

If this function is defined by the public module provider, it is called during module load time by the private layer, with the contents of the RESOURCE_CONFIG string acquired by the administrative interface (in the case of the `dhcpcmgr`, through the use of a public module-specific java bean extending the `dhcpcmgr` to provide a configuration dialog for this information.

RUN_MODE

`server` or `relay`. Selects daemon run mode. Default is `server`.

SECONDARY_SERVER_TIMEOUT

Integer. The number of seconds a secondary server will wait for a primary server to respond before responding itself. Default is 20 seconds. This is a *server* mode only parameter.

UPDATE_TIMEOUT

Integer. Number of minutes to wait for a response from the DNS server before timing out. If this parameter is present, the DHCP daemon will update DNS on behalf of DHCP clients, and will wait the number of seconds specified for a response before timing out. You can use `UPDATE_TIMEOUT` without specifying a number to enable DNS updates with the default timeout of 15 seconds. If this parameter is not present, the DHCP daemon will not update DNS for DHCP clients.

VERBOSE

`TRUE/FALSE`. Toggles verbose mode, determining amount of status and error messages reported by the daemon. Default is `FALSE`. Set to `TRUE` only for debugging. Generic parameter.

dhcptab(4)

NAME	dhcptab – DHCP configuration parameter table						
DESCRIPTION	<p>The dhcptab configuration table allows network administrators to organize groups of configuration parameters as macro definitions, which can then be referenced in the definition of other useful macros. These macros are then used by the DHCP server to return their values to DHCP and BOOTP clients.</p> <p>The preferred method of managing the dhcptab is through the use of the dhcprmgr(1M) or dhctadm(1M) utility. The description of dhcptab entries included in this manual page is intended for informational purposes only, and should not be used to manually edit entries.</p> <p>You can view the contents of the dhcptab using the DHCP manager's tabs for Macros and Options, or using the dhctadm -P command.</p>						
Syntax of dhcptab Entries	<p>The format of a dhcptab table depends on the data store used to maintain it. However, any dhcptab must contain the following fields in each record:</p> <table><tr><td>Name</td><td>This field identifies the macro or symbol record and is used as a search key into the dhcptab table. The name of a macro or symbol must consist of ASCII characters, with the length limited to 128 characters. Names can include spaces, except at the end of the name. The name is not case-sensitive.</td></tr><tr><td>Type</td><td>This field specifies the type of record and is used as a search key into the dhcptab. Currently, there are only two legal values for Type: m This record is a DHCP macro definition. s This record is a DHCP symbol definition. It is used to define vendor and site-specific options.</td></tr><tr><td>Value</td><td>This field contains the value for the specified type of record. For the m type, the value will consist of a series of symbol=value pairs, separated by the colon (:) character. For the s type, the value will consist of a series of fields, separated by a comma (,), which define a symbol's characteristics. Once defined, a symbol can be used in macro definitions.</td></tr></table>	Name	This field identifies the macro or symbol record and is used as a search key into the dhcptab table. The name of a macro or symbol must consist of ASCII characters, with the length limited to 128 characters. Names can include spaces, except at the end of the name. The name is not case-sensitive.	Type	This field specifies the type of record and is used as a search key into the dhcptab. Currently, there are only two legal values for Type: m This record is a DHCP macro definition. s This record is a DHCP symbol definition. It is used to define vendor and site-specific options.	Value	This field contains the value for the specified type of record. For the m type, the value will consist of a series of symbol=value pairs, separated by the colon (:) character. For the s type, the value will consist of a series of fields, separated by a comma (,), which define a symbol's characteristics. Once defined, a symbol can be used in macro definitions.
Name	This field identifies the macro or symbol record and is used as a search key into the dhcptab table. The name of a macro or symbol must consist of ASCII characters, with the length limited to 128 characters. Names can include spaces, except at the end of the name. The name is not case-sensitive.						
Type	This field specifies the type of record and is used as a search key into the dhcptab. Currently, there are only two legal values for Type: m This record is a DHCP macro definition. s This record is a DHCP symbol definition. It is used to define vendor and site-specific options.						
Value	This field contains the value for the specified type of record. For the m type, the value will consist of a series of symbol=value pairs, separated by the colon (:) character. For the s type, the value will consist of a series of fields, separated by a comma (,), which define a symbol's characteristics. Once defined, a symbol can be used in macro definitions.						
Symbol Characteristics	<p>The Value field of a symbols definition contain the following fields describing the characteristics of a symbol:</p> <table><tr><td>Context</td><td>This field defines the context in which the symbol definition is to be used. It can have one of the following values: Site This symbol defines a site-specific option, codes 128-254. Vendor=Client Class ... This symbol defines a vendor-specific option, codes 1-254. The Vendor context takes ASCII string arguments which identify the</td></tr></table>	Context	This field defines the context in which the symbol definition is to be used. It can have one of the following values: Site This symbol defines a site-specific option, codes 128-254. Vendor=Client Class ... This symbol defines a vendor-specific option, codes 1-254. The Vendor context takes ASCII string arguments which identify the				
Context	This field defines the context in which the symbol definition is to be used. It can have one of the following values: Site This symbol defines a site-specific option, codes 128-254. Vendor=Client Class ... This symbol defines a vendor-specific option, codes 1-254. The Vendor context takes ASCII string arguments which identify the						

	<p>client class that this vendor option is associated with. Multiple client class names can be specified, separated by white space. Only those clients whose client class matches one of these values will see this option. For Sun machines, the Vendor client class matches the value returned by the command <code>uname -i</code> on the client, with periods replacing commas.</p>
Code	<p>This field specifies the option code number associated with this symbol. Valid values are 128-254 for site-specific options, and 1-254 for vendor-specific options.</p>
Type	<p>This field defines the type of data expected as a value for this symbol, and is not case-sensitive. Legal values are:</p> <p>ASCII NVT ASCII text. Value is enclosed in double-quotes ("). Granularity setting has no effect on symbols of this type, since ASCII strings have a natural granularity of one (1).</p> <p>BOOLEAN No value is associated with this data type. Presence of symbols of this type denote boolean <code>TRUE</code>, whereas absence denotes <code>FALSE</code>. Granularity and Miximum values have no meaning for symbols of this type.</p> <p>IP Dotted decimal form of an Internet address. Multi-IP address granularity is supported.</p> <p>NUMBER An unsigned number with a supported granularity of 1, 2, 4, and 8 octets.</p> <p>Valid NUMBER types are: <code>UNNUMBER8</code>, <code>SNUMBER8</code>, <code>UNNUMBER16</code>, <code>SNUMBER16</code>, <code>UNNUMBER32</code>, <code>SNUMBER32</code>, <code>UNNUMBER64</code>, and <code>SNUMBER64</code>. See <code>dhcp_inittab(4)</code> for details.</p> <p>OCTET Uninterpreted ASCII representation of binary data. The client identifier is one example of an <code>OCTET</code> string. Valid characters are 0-9, [a-f] [A-F]. One ASCII character represents one nibble (4 bits), thus two ASCII characters are needed to represent an 8 bit quantity. The granularity setting has no effect on symbols of this type, since <code>OCTET</code> strings have a natural granularity of one (1).</p>
Granularity	<p>This value specifies how many objects of <code>Type</code> define a single instance of the symbol value. For example, the static route option is defined to be a variable list of routes. Each route consists of two IP addresses, so the <code>Type</code> is defined to be <code>IP</code>, and the data's</p>

dhcptab(4)

Macro Definitions

granularity is defined to be 2 IP addresses. The granularity field affects the IP and NUMBER data types.

Maximum This value specifies the maximum items of Granularity which are permissible in a definition using this symbol. For example, there can only be one IP address specified for a subnet mask, so the Maximum number of items in this case is one (1). A Maximum value of zero (0) means that a variable number of items is permitted.

The following example defines a site-specific option (symbol) called `MystatRt`, of code 130, type IP, and granularity 2, and a Maximum of 0. This definition corresponds to the internal definition of the static route option (`StaticRt`).

```
MystatRt s Site,130,IP,2,0
```

The following example illustrates a macro defined using the `MystatRt` site option symbol just defined:

```
10netnis m :MystatRt=3.0.0.0 10.0.0.30:Macros can be specified in the Macro field in DHCP network tables (see dhcp_network(4)), which will bind particular macro definitions to specific IP addresses.
```

Up to four macro definitions are consulted by the DHCP server to determine the options that are returned to the requesting client.

These macros are processed in the following order:

Client Class A macro named using the ASCII representation of the client class (e.g. `SUNW.Ultra-30`) is searched for in the `dhcptab`. If found, its symbol/value pairs will be selected for delivery to the client. This mechanism permits the network administrator to select configuration parameters to be returned to all clients of the same class.

Network A macro named by the dotted Internet form of the network address of the client's network (for example, `10.0.0.0`) is searched for in the `dhcptab`. If found, its symbol/value pairs will be combined with those of the `Client Class` macro. If a symbol exists in both macros, then the `Network` macro value overrides the value defined in the `Client Class` macro. This mechanism permits the network administrator to select configuration parameters to be returned to all clients on the same network.

IP Address This macro may be named anything, but must be specified in the DHCP network table for the IP address

dhcptab(4)

record assigned to the requesting client. If this macro is found in the `dhcptab`, then its symbol/value pairs will be combined with those of the `Client Class` macro and the `Network` macro. This mechanism permits the network administrator to select configuration parameters to be returned to clients using a particular IP address. It can also be used to deliver a macro defined to include "server-specific" information by including this macro definition in all DHCP network table entries owned by a specific server.

Client Identifier

A macro named by the ASCII representation of the client's unique identifier as shown in the DHCP network table (see `dhcp_network(4)`). If found, its symbol/value pairs are combined to the sum of the `Client Class`, `Network`, and `IP Address` macros. Any symbol collisions are replaced with those specified in the client identifier macro. The client mechanism permits the network administrator to select configuration parameters to be returned to a particular client, regardless of what network that client is connected to.

Refer to *System Administration Guide: IP Services* for more information about macro processing.

Refer to the `dhcp_inittab(4)` man page for more information about symbols used in Solaris DHCP.

dialups(4)

NAME	dialups – list of terminal devices requiring a dial-up password				
SYNOPSIS	<code>/etc/dialups</code>				
DESCRIPTION	<p><code>dialups</code> is an ASCII file which contains a list of terminal devices that require a dial-up password. A dial-up password is an additional password required of users who access the computer through a modem or dial-up port. The correct password must be entered before the user is granted access to the computer. The set of ports that require a dial-up password are listed in the <code>dialups</code> file.</p> <p>Each entry in the <code>dialups</code> file is a single line of the form:</p> <pre><i>terminal-device</i></pre> <p>where</p> <pre><i>terminal-device</i> The full path name of the terminal device that will require a dial-up password for users accessing the computer through a modem or dial-up port.</pre> <p>The <code>dialups</code> file should be owned by the <code>root</code> user and the <code>root</code> group. The file should have read and write permissions for the owner (<code>root</code>) only.</p>				
EXAMPLES	<p>EXAMPLE 1 A sample <code>dialups</code> file.</p> <p>Here is a sample <code>dialups</code> file:</p> <pre>/dev/term/a /dev/term/b /dev/term/c</pre>				
FILES	<table><tr><td><code>/etc/d_passwd</code></td><td>dial-up password file</td></tr><tr><td><code>/etc/dialups</code></td><td>list of dial-up ports requiring dial-up passwords</td></tr></table>	<code>/etc/d_passwd</code>	dial-up password file	<code>/etc/dialups</code>	list of dial-up ports requiring dial-up passwords

SEE ALSO	<code>d_passwd(4)</code>				

NAME	dir_ufs, dir – format of ufs directories				
SYNOPSIS	<pre>#include <sys/param.h> #include <sys/types.h> #include <sys/fs/ufs/fsdir.h></pre>				
DESCRIPTION	<p>A directory consists of some number of blocks of DIRBLKSIZ bytes, where DIRBLKSIZ is chosen such that it can be transferred to disk in a single atomic operation (for example, 512 bytes on most machines).</p> <p>Each DIRBLKSIZ-byte block contains some number of directory entry structures, which are of variable length. Each directory entry has a <code>struct direct</code> at the front of it, containing its inode number, the length of the entry, and the length of the name contained in the entry. These entries are followed by the name padded to a 4 byte boundary with null bytes. All names are guaranteed null-terminated. The maximum length of a name in a directory is MAXNAMLEN.</p> <pre>#define DIRBLKSIZ DEV_BSIZE #define MAXNAMLEN 256 struct direct { ulong_t d_ino; /* inode number of entry */ ushort_t d_reclen; /* length of this record */ ushort_t d_namlen; /* length of string in d_name */ char d_name[MAXNAMLEN + 1]; /* maximum name length */ };</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for a description of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Stability Level</td> <td>Unstable</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Stability Level	Unstable
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Stability Level	Unstable				
SEE ALSO	<code>fs_ufs(4)</code> , <code>attributes(5)</code>				

d_passwd(4)

NAME	d_passwd – dial-up password file				
SYNOPSIS	/etc/d_passwd				
DESCRIPTION	<p>A dial-up password is an additional password required of users who access the computer through a modem or dial-up port. The correct password must be entered before the user is granted access to the computer.</p> <p>d_passwd is an ASCII file which contains a list of executable programs (typically shells) that require a dial-up password and the associated encrypted passwords. When a user attempts to log in on any of the ports listed in the dialups file (see dialups(4)), the login program looks at the user's login entry stored in the passwd file (see passwd(4)), and compares the login shell field to the entries in d_passwd. These entries determine whether the user will be required to supply a dial-up password.</p> <p>Each entry in d_passwd is a single line of the form:</p> <pre>login-shell : password :</pre> <p>where</p> <table><tr><td><i>login-shell</i></td><td>The name of the login program that will require an additional dial-up password.</td></tr><tr><td><i>password</i></td><td>A 13-character encrypted password. Users accessing the computer through a dial-up port or modem using <i>login-shell</i> will be required to enter this password before gaining access to the computer.</td></tr></table> <p>d_passwd should be owned by the root user and the root group. The file should have read and write permissions for the owner (root) only.</p> <p>If the user's login program in the passwd file is not found in d_passwd or if the login shell field in passwd is empty, the user must supply the default password. The default password is the entry for /usr/bin/sh. If d_passwd has no entry for /usr/bin/sh, then those users whose login shell field in passwd is empty or does not match any entry in d_passwd will not be prompted for a dial-up password.</p> <p>Dial-up logins are disabled if d_passwd has only the following entry:</p> <pre>/usr/bin/sh:* :</pre>	<i>login-shell</i>	The name of the login program that will require an additional dial-up password.	<i>password</i>	A 13-character encrypted password. Users accessing the computer through a dial-up port or modem using <i>login-shell</i> will be required to enter this password before gaining access to the computer.
<i>login-shell</i>	The name of the login program that will require an additional dial-up password.				
<i>password</i>	A 13-character encrypted password. Users accessing the computer through a dial-up port or modem using <i>login-shell</i> will be required to enter this password before gaining access to the computer.				
EXAMPLES	<p>EXAMPLE 1 Sample d_passwd file.</p> <p>Here is a sample d_passwd file:</p> <pre>/usr/lib/uucp/uucico:q.mJzTnu8icF0: /usr/bin/csh:6k/7KCFRPNVXg: /usr/bin/ksh:9df/FDf.4jkRt: /usr/bin/sh:41FuGVzGcDJlw:</pre>				

EXAMPLE 1 Sample d_passwd file. (Continued)

Generating An Encrypted Password

The passwd (see passwd(1)) utility can be used to generate the encrypted password for each login program. passwd generates encrypted passwords for users and places the password in the shadow (see shadow(4)) file. Passwords for the d_passwd file will need to be generated by first adding a temporary user id using useradd (see useradd(1M)), and then using passwd(1) to generate the desired password in the shadow file. Once the encrypted version of the password has been created, it can be copied to the d_passwd file.

For example:

1. Type useradd tempuser and press Return. This creates a user named tempuser.
2. Type passwd tempuser and press Return. This creates an encrypted password for tempuser and places it in the shadow file.
3. Find the entry for tempuser in the shadow file and copy the encrypted password to the desired entry in the d_passwd file.
4. Type userdel tempuser and press Return to delete tempuser.

These steps must be executed as the root user.

FILES	/etc/d_passwd	dial-up password file
	/etc/dialups	list of dial-up ports requiring dial-up passwords
	/etc/passwd	password file
	/etc/shadow	shadow password file

SEE ALSO passwd(1), useradd(1M), dialups(4), passwd(4), shadow(4)

WARNINGS When creating a new dial-up password, be sure to remain logged in on at least one terminal while testing the new password. This ensures that there is an available terminal from which you can correct any mistakes that were made when the new password was added.

driver.conf(4)

NAME	driver.conf – driver configuration files
SYNOPSIS	<code>driver.conf</code>
DESCRIPTION	<p>Driver configuration files pass information about device drivers and their configuration to the system. Most device drivers do not have to have configuration files. Drivers for devices that are self-identifying, such as the SBus devices on many systems, can usually obtain all the information they need from the FCode PROM on the SBus card using the DDI property interfaces. See <code>ddi_prop_get_int(9F)</code> and <code>ddi_prop_lookup(9F)</code> for details.</p> <p>The system associates a driver with its configuration file by name. For example, a driver in <code>/usr/kernel/drv</code> called <code>wombat</code> has the driver configuration file <code>wombat.conf</code> associated with it. On systems capable of support 64-bit drivers, the driver configuration file should be placed in the directory in which the 32-bit driver is (or would be) located, even if only a 64-bit version is provided.</p> <p>The value of the <code>name</code> property (see the <code>name</code> field, below) needs to match the binding name of the device. The binding name is the name chosen by the system to bind a driver to a device and is either an alias associated with the driver or the hardware node name of the device.</p> <p>The syntax of a single entry in a driver configuration file takes one of three forms:</p> <pre>name="node name" parent="parent name" [property-name=value ...];</pre> <p>In this form, the <code>parent</code> name can be either a simple nexus driver name to match all instances of that parent/node, or the <code>parent</code> name can be a specific full pathname, beginning with a slash (/) character, identifying a specific instance of a parent bus.</p> <p>Alternatively, the <code>parent</code> can be specified by the type of interface it presents to its children.</p> <pre>name="node name" class="class name" [property-name=value ...];</pre> <p>For example, the driver for the SCSI host adapter may have different names on different platforms, but the target drivers can use class <code>scsi</code> to insulate themselves from these differences.</p> <p>Entries of either form above correspond to a device information (<code>devinfo</code>) node in the kernel device tree. Each node has a <code>name</code> which is usually the name of the driver, and a <code>parent</code> name which is the name of the parent <code>devinfo</code> node it will be connected to. Any number of name-value pairs may be specified to create properties on the prototype <code>devinfo</code> node. These properties can be retrieved using the DDI property interfaces (for example, <code>ddi_prop_get_int(9F)</code> and <code>ddi_prop_lookup(9F)</code>). The prototype <code>devinfo</code> node specification must be terminated with a semicolon (;).</p> <p>The third form of an entry is simply a list of properties.</p> <pre>[property-name=value ...];</pre>

A property created in this way is treated as global to the driver. It can be overridden by a property with the same name on a particular `devinfo` node, either by creating one explicitly on the prototype node in the `driver.conf` file or by the driver.

Items are separated by any number of newlines, SPACE or TAB characters.

The configuration file may contain several entries to specify different device configurations and parent nodes. The system may call the driver for each possible prototype `devinfo` node, and it is generally the responsibility of the driver's `probe(9E)` routine to determine if the hardware described by the prototype `devinfo` node is really present.

Property names must not violate the naming conventions for Open Boot PROM properties or for IEEE 1275 names. In particular, property names should contain only printable characters, and should not contain at-sign (@), slash (/), backslash (\), colon (:), or square brackets ([]). Property values can be decimal integers or strings delimited by double quotes ("). Hexadecimal integers can be constructed by prefixing the digits with 0x.

A comma separated list of integers can be used to construct properties whose value is an integer array. The value of such properties can be retrieved inside the driver using `ddi_prop_lookup_int_array(9F)`.

Comments are specified by placing a # character at the beginning of the comment string, the comment string extends for the rest of the line.

EXAMPLES

EXAMPLE 1 Configuration File for a PCI Bus Frame Buffer

The following is an example of a configuration file called `ACME, simple.conf` for a PCI bus frame buffer called `ACME, simple`.

```
#
# Copyright (c) 1993, by ACME Fictitious Devices, Inc.
#
#ident "@(#)ACME,simple.conf 1.3 1999/09/09"

name="ACME,simple" class="pci" unit-address="3,1"
        debug-mode=12;
```

This example creates a prototype `devinfo` node called `ACME, simple` under all parent nodes of class `pci`. The node has device and function numbers of 3 and 1, respectively; the property `debug-mode` is provided for all instances of the driver.

EXAMPLE 2 Configuration File for a Pseudo Device Driver

The following is an example of a configuration file called `ACME, example.conf` for a pseudo device driver called `ACME, example`.

```
#
# Copyright (c) 1993, ACME Fictitious Devices, Inc.
#
```

driver.conf(4)

EXAMPLE 2 Configuration File for a Pseudo Device Driver (Continued)

```
#ident      "@(#) ACME,example.conf  1.2  93/09/09"
name="ACME,example" parent="pseudo" instance=0
    debug-level=1;

name="ACME,example" parent="pseudo" instance=1;

whizzy-mode="on";
debug-level=3;
```

This creates two devinfo nodes called `ACME,example` which will attach below the `pseudo` node in the kernel device tree. The `instance` property is only interpreted by the `pseudo` node, see `pseudo(4)` for further details. A property called `debug-level` will be created on the first devinfo node which will have the value 1. The `example` driver will be able to fetch the value of this property using `ddi_prop_get_int(9F)`.

Two global driver properties are created, `whizzy-mode` (which will have the string value "on") and `debug-level` (which will have the value 3). If the driver looks up the property `whizzy-mode` on either node, it will retrieve the value of the global `whizzy-mode` property ("on"). If the driver looks up the `debug-level` property on the first node, it will retrieve the value of the `debug-level` property on that node (1). Looking up the same property on the second node will retrieve the value of the global `debug-level` property (3).

SEE ALSO `pci(4)`, `pseudo(4)`, `sbus(4)`, `scsi(4)`, `pci(4)`, `probe(9E)`, `ddi_getlongprop(9F)`, `ddi_getprop(9F)`, `ddi_getproplen(9F)`, `ddi_prop_op(9F)`

Writing Device Drivers

WARNINGS To avoid namespace collisions between multiple driver vendors, it is strongly recommended that the `name` property of the driver should begin with a vendor-unique string. A reasonably compact and unique choice is the vendor over-the-counter stock symbol.

NOTES The `update_drv(1M)` command should be used to prompt the kernel to reread `driver.conf` files. Using `modunload(1M)` to update `driver.conf` continues to work in release 9 of the Solaris operating environment, but the behavior will change in a future release.

NAME	environ, pref, variables – user-preference variables files for AT&T FACE
SYNOPSIS	<pre>\$HOME/pref/.environ \$HOME/pref/.variables \$HOME/FILECABINET/.pref \$HOME/WASTEBASKET/.pref</pre>
DESCRIPTION	<p>The .environ, .pref, and .variables files contain variables that indicate user preferences for a variety of operations. The .environ and .variables files are located under the user's \$HOME/pref directory. The .pref files are found under \$HOME/FILECABINET, \$HOME/WASTEBASKET, and any directory where preferences were set via the organize command. Names and descriptions for each variable are presented below. Variables are listed one per line and are of the form <i>variable=value</i>.</p>
.environ Variables	<p>Variables found in .environ include:</p> <p>LOGINWIN [1-4] Windows that are opened when FACE is initialized.</p> <p>SORTMODE Sort mode for file folder listings. Values include the following hexadecimal digits:</p> <p style="padding-left: 40px;">1 Sorted alphabetically by name.</p> <p style="padding-left: 40px;">2 Files most recently modified first.</p> <p style="padding-left: 40px;">800 Sorted alphabetically by object type.</p> <p style="padding-left: 40px;">The values above may be listed in reverse order by ORing the following value:</p> <p style="padding-left: 40px;">1000 List objects in reverse order. For example, a value of 1002 will produce a folder listing with files LEAST recently modified displayed first. A value of 1001 would produce a "reverse" alphabetical by name listing of the folder.</p> <p>DISPLAYMODE Display mode for file folders. Values include the following hexadecimal digits:</p> <p style="padding-left: 40px;">0 File names only.</p> <p style="padding-left: 40px;">4 File names and brief description.</p> <p style="padding-left: 40px;">8 File names, description, plus additional information.</p> <p>WASTEPROMPT Prompt before emptying wastebasket (yes/no?).</p> <p>WASTEDAYS Number of days before emptying wastebasket.</p> <p>PRINCMD[1-3] Print command defined to print files.</p> <p>UMASK Holds default permissions with which files will be created.</p>

environ(4)

.pref Variables | Variables found in `.pref` are the following:

`SORTMODE` Contains the same values as the `SORTMODE` variable described in `.environ` above.

`DISPMODE` Contains the same values as the `DISPLAYMODE` variable described in `.environ` above.

.variable Variables | Variables found in `.variables` include:

`EDITOR` Default editor.

`PS1` Shell prompt.

NAME	ethers – Ethernet address to hostname database or domain
DESCRIPTION	<p>The <code>ethers</code> file is a local source of information about the (48 bit) Ethernet addresses of hosts on the Internet. The <code>ethers</code> file can be used in conjunction with or instead of other <code>ethers</code> sources, including the NIS maps <code>ethers.byname</code> and <code>ethers.byaddr</code> and the NIS+ table <code>ethers</code>. Programs use the <code>ethers(3SOCKET)</code> routines to access this information.</p> <p>The <code>ethers</code> file has one line for each host on an Ethernet. The line has the following format:</p> <p><i>Ethernet-address official-host-name</i></p> <p>Items are separated by any number of SPACE and/or TAB characters. A '#' indicates the beginning of a comment extending to the end of line.</p> <p>The standard form for Ethernet addresses is "<code>x:x:x:x:x:x</code>" where <code>x</code> is a hexadecimal number between 0 and ff, representing one byte. The address bytes are always in network order. Host names may contain any printable character other than SPACE, TAB, NEWLINE, or comment character.</p>
FILES	<code>/etc/ethers</code>
SEE ALSO	<code>ethers(3SOCKET)</code> , <code>hosts(4)</code> , <code>nsswitch.conf(4)</code>

exec_attr(4)

NAME	exec_attr – execution profiles database
SYNOPSIS	/etc/security/exec_attr
DESCRIPTION	<p>/etc/security/exec_attr is a local database that specifies the execution attributes associated with profiles. The <code>exec_attr</code> file can be used with other sources for execution profiles, including the <code>exec_attr</code> NIS map and NIS+ table. Programs use the <code>getexecattr(3SECDB)</code> routines to access this information.</p> <p>The search order for multiple execution profile sources is specified in the <code>/etc/nsswitch.conf</code> file, as described in the <code>nsswitch.conf(4)</code> man page. The search order follows the entry for <code>prof_attr(4)</code>.</p> <p>A profile is a logical grouping of authorizations and commands that is interpreted by a profile shell to form a secure execution environment. The shells that interpret profiles are <code>pfsh</code>, <code>pfksh</code>, and <code>pfsh</code>. See the <code>pfsh(1)</code> man page. Each user's account is assigned zero or more profiles in the <code>user_attr(4)</code> database file.</p> <p>Each entry in the <code>exec_attr</code> database consists of one line of text containing seven fields separated by colons (:). Line continuations using the backslash (\) character are permitted. The basic format of each entry is:</p> <pre><i>name:policy:type:res1:res2:id:attr</i></pre> <p><i>name</i> The name of the profile. Profile names are case-sensitive.</p> <p><i>policy</i> The policy that is associated with the profile entry. The only valid <i>policy</i> is <code>suser</code>.</p> <p><i>type</i> The type of object defined in the profile. The only valid type is <code>cmd</code>.</p> <p><i>res1</i> Reserved for future use.</p> <p><i>res2</i> Reserved for future use.</p> <p><i>id</i> A string that uniquely identifies the object described by the profile. For a profile of type <code>cmd</code>, the <i>id</i> is either the full path to the command or the asterisk (*) symbol, which is used to allow all commands. An asterisk that replaces the filename component in a pathname indicates all files in a particular directory. To specify arguments, the pathname should point to a shell script written to execute the command with the desired arguments.</p> <p><i>attr</i> An optional list of semicolon-separated (;) key-value pairs that describe the security attributes to apply to the object upon execution. Zero or more keys may be specified. The list of valid key words depends on the policy enforced. The following key words are valid: <code>euid</code>, <code>uid</code>, <code>egid</code>, and <code>gid</code>.</p>

exec_attr(4)

`eid` and `uid` contain a single user name or a numeric user ID. Commands designated with `eid` run with the effective UID indicated, which is similar to setting the `setuid` bit on an executable file. Commands designated with `uid` run with both the real and effective UIDs. Setting `uid` may be more appropriate than setting the `eid` on privileged shell scripts.

`egid` and `gid` contain a single group name or a numeric group ID. Commands designated with `egid` run with the effective GID indicated, which is similar to setting the `setgid` bit on a file. Commands designated with `gid` run with both the real and effective GIDs. Setting `gid` may be more appropriate than setting `gid` on privileged shell scripts.

EXAMPLES **EXAMPLE 1** Using effective user and group IDs

The following example shows the `audit` command specified in the Audit Control profile to execute with an effective user ID of `root` (0) and effective group ID of `bin` (3):

```
Audit Control:suser:cmd:::/etc/init.d/audit:eid=0;egid=3
```

FILES `/etc/nsswitch.conf`
`/etc/user_attr`
`/etc/security/exec_attr`

CAVEATS When deciding which authorization source to use (see **DESCRIPTION**), keep in mind that NIS+ provides stronger authentication than NIS.

Because the list of legal keys is likely to expand, any code that parses this database must be written to ignore unknown key-value pairs without error. When any new keywords are created, the names should be prefixed with a unique string, such as the company's stock symbol, to avoid potential naming conflicts.

The following characters are used in describing the database format and must be escaped with a backslash if used as data: colon (:), semicolon (;), equals (=), and backslash (\).

SEE ALSO `auths(1)`, `profiles(1)`, `roles(1)`, `makedbm(1M)`, `getauthattr(3SECDB)`, `getauusernam(3BSM)`, `getexecattr(3SECDB)`, `getprofattr(3SECDB)`, `getuserattr(3SECDB)`, `kva_match(3SECDB)`, `auth_attr(4)`, `prof_attr(4)`, `user_attr(4)`

fd(4)

NAME	fd – file descriptor files
DESCRIPTION	<p>These files, conventionally called <code>/dev/fd/0</code>, <code>/dev/fd/1</code>, <code>/dev/fd/2</code>, and so on, refer to files accessible through file descriptors. If file descriptor <i>n</i> is open, these two system calls have the same effect:</p> <pre>fd = open("/dev/fd/n", mode); fd = dup(n);</pre> <p>On these files <code>creat(2)</code> is equivalent to <code>open</code>, and <code>mode</code> is ignored. As with <code>dup</code>, subsequent reads or writes on <code>fd</code> fail unless the original file descriptor allows the operations.</p> <p>For convenience in referring to standard input, standard output, and standard error, an additional set of names is provided: <code>/dev/stdin</code> is a synonym for <code>/dev/fd/0</code>, <code>/dev/stdout</code> for <code>/dev/fd/1</code>, and <code>/dev/stderr</code> for <code>/dev/fd/2</code>.</p>
SEE ALSO	<code>creat(2)</code> , <code>dup(2)</code> , <code>open(2)</code>
DIAGNOSTICS	<code>open(2)</code> returns <code>-1</code> and <code>EBADF</code> if the associated file descriptor is not open.

NAME	flash_archive – format of flash archive
SYNOPSIS	flash_archive
DESCRIPTION	<p>A flash archive is an easily transportable version of a reference configuration of the Solaris operating environment, plus optional other software. Such an archive is used for the rapid installation of Solaris on large numbers of machines. The machine that contains a flash archive is referred to as a master system. A machine that receives a copy of a flash archive is called a clone system.</p> <p>Flash archives are monolithic files containing both archive identification information and the actual files that have been copied from a master system and that will be extracted onto a clone system.</p> <p>The flash archive is laid out in the following sections:</p> <ul style="list-style-type: none"> ■ archive cookie ■ archive identification ■ user-defined (optional) ■ archive files <p>The only assumptions regarding section number and placement that an application processing the archive can make is that there is an identification section located immediately after the archive cookie and that the last section in the archive is an archive files section.</p> <p>These sections are described in the following subsections.</p> <p>Archive Cookie The very beginning of the archive contains a cookie, which serves to identify the file as a flash archive. It is also used by the deployment code for identification and validation purposes.</p> <p>The case-sensitive, newline-terminated cookie that identifies version 1.0 flash archives, is <code>FLAsH-aRcHiVe-1.0</code>.</p> <p>The archive version is designed to allow for the future evolution of the flash archive specification while allowing applications that process flash archives to determine whether specific archives are of a format that can be handled correctly. The archive version is a number of the form <code>x.y</code>, where <code>x</code> is the major version number, and <code>y</code> is the minor version number.</p> <p>The major and/or minor version numbers must be incremented when changes are made to the archive specification. The type and impact of the changes being made determine which of the version numbers must be incremented. A minor change, indicated by an incrementing of the minor version number, is one that will not negatively impact an application's ability to extract the archive. A major change, indicated by an incrementing of the major version number, is the converse. When an application encounters a flash archive with an unknown major version number, it should issue an error message and exit.</p>

flash_archive(4)

Archive Identification Section

The archive identification section is plain text, delimited with newline characters. It is composed of a series of keyword/value pairs, with one pair allowed per line. Keywords and values are separated by a single equal sign. There are no limits to the length of individual lines. Binary data to be included as the value to a keyword is base64 encoded. The keywords themselves are case-insensitive. The case-sensitivity of the values is determined by the definition of the keyword, though most are case-insensitive.

The global order of the keywords within the identification section is undefined, save for the section boundary keywords. The identification section must begin with `section_begin=ident` and must end with `section_end=ident`.

In addition to the keywords defined for the flash archive and enumerated below, users can define their own. These user-defined keywords are ignored by the flash mechanisms, but can be used by user-provided scripts or programs that process the identification section. User-defined keywords must begin with `X`, and contain characters other than linefeeds, equal signs, and null characters. For example, `X-department` is a valid user-defined keyword. `department`, which lacks the `X`-prefix, is not. Suggested naming conventions for user-defined keyword include the underscore-delimited descriptive method used for the pre-defined keywords, or a federated convention similar to that used to name Java packages.

Applications that process the identification section will process unrecognized non-user-defined keyword differently, depending on whether the archive version is known. If the application recognizes the archive specification version, it will reject any unrecognized non-user-defined keyword. If the application does not recognize the specification version, that is, if the minor version number is higher than the highest minor version it knows how to process, unrecognized non-user-defined keywords will be ignored. These ignored keyword are reported to the user by means of a non-fatal warning message.

The keywords defined for this version of the Flash archive specification are listed below.

Keyword	Value	Required
<code>section_begin</code>	text	yes
<code>section_end</code>	text	yes
<code>archive_id</code>	text	no
<code>files_archived_method</code>	text	no
<code>files_compressed_method</code>	text	no
<code>files_archived_size</code>	numeric	no
<code>files_unarchived_size</code>	numeric	no

Keyword	Value	Required
creation_date	text	no
creation_master	text	no
content_name	text	yes
content_type	text	no
content_description	text	no
content_author	text	no
content_architectures	text list	no

Note that future versions of the identification section might define additional keywords. The only guarantee regarding the new keywords is that they will not intrude upon the user-defined keyword namespace as given above.

The following is an example identification section:

```
section_begin=identification
files_archived_method=cpio
files_compressed_method=compress
files_archived_size=259323342
files_unarchived_size=591238111
creation_date=20000131221409
creation_master=pumbaa
content_name=Finance Print Server
content_type=server

```

The following are descriptions of the identification section keywords:

```
section_begin
section_end
```

These keywords are used to delimit sections in the archive and are not limited exclusively to the identification section. For example, the archive files section includes a `section_begin` keyword, though with a different value. User-defined archive sections will be delimited by `section_begin` and `section_end` keywords, with values appropriate to each section. The currently defined section names are given in the table below. User-defined names should follow the same convention as user-defined identification sections, with the additional restriction that they not contain forward slashes (/).

flash_archive(4)

Section	Boundary
identification	identification
archive files	archive
archive cookie	cookie

Note that while the archive cookie does not use section boundaries, and thus has no need for a section name within the archive itself, the `flar(1M)` command uses section names when splitting the archive, and thus requires a section name for the archive cookie. The name `cookie` is reserved for that purpose.

The following four keywords, used in the archive identification section, describe the contents of the archive files section.

`archive_id`

This optional keyword *uniquely* describes the contents of the archive. It is computed as a unique hash value of the bytes representing the archive. Currently this value is represented as an ASCII hexadecimal 128-bit MD5 hash of the archive contents. This value is used by the installation software only to validate the contents of the archive during archive installation.

If the keyword is present, the hash value is recomputed during extraction based on the contents of the archive being extracted. If the recomputed value does not match the stored value in the identification section, then the archive is deemed corrupt, and appropriate actions can be taken by the application.

If the keyword is not present, then no integrity check is performed.

`files_archived_method`

This keyword describes the archive method used in the files section. If this keyword is not present, the files section is assumed to be in CPIO format with ASCII headers (the `-c` option to `cpio`). If the keyword is present, it can have the following value:

`cpio` The archive format in the files section is CPIO with ASCII headers.

The compression method indicated by the `files_compressed_method` keyword (if present) is applied to the archive file created by the archive method.

The introduction of additional archive methods will require a change in the major archive specification version number, as applications aware only of `cpio` will be unable to extract archives that use other archive methods.

`files_compressed_method`

This keyword describes the compression algorithm (if any) used on the files section. If this keyword is not present, the files section is assumed to be uncompressed. If the keyword is present, it can have one of the following values:

`none` The files section is not compressed.
`compress` The files section is compressed using `compress(1)`.

The compression method indicated by this keyword is applied to the archive file created by the archive method indicated by the value of the `files_archived_method` keyword (if any). `gzip` compression of the flash archive is not currently supported, as the `gzip` decompression program is not included in the standard miniroot.

Introduction of an additional compression algorithm would require a change in the major archive specification version number, as applications aware only of the above methods will be unable to extract archives that use other compression algorithms.

`files_archived_size`

The value associated with this keyword is the size of the archived files section, in bytes. This value is used by the deployment software only to give extraction progress information to the user. While the deployment software can easily determine the size of the archived files section prior to extraction, it cannot do so in the case of archive retrieval via a stream. To determine the compressed size when extracting from a stream, the extraction software would have to read the stream twice. This double read would result in an unacceptable performance penalty compared to the value of the information gathered.

If the keyword is present, the value is used only for the provision of status information. Because this keyword is only advisory, deployment software must be able to handle extraction of archives for which the actual file section size does not match the size given in `files_archive_size`.

If `files_archive_size` is not present and the archive is being read from a stream device that does not allow the prior determination of size information, such as a tape drive, completion status information will not be generated. If the keyword is not present and the archive is being read from a random-access device such as a mounted filesystem, or from a stream that provides size information, the compressed size will be generated dynamically and used for the provision of status information.

`files_unarchived_size`

This keyword defines the cumulative size in bytes of the extracted archive. The value is used for filesystem size verification. The following verification methods are possible using this approach:

No checking If the `files_unarchived_size` keyword is absent, no spacechecking will be performed.

flash_archive(4)

Aggregate checking If the `files_unarchived_size` keyword is present and the associated value is an integer, the integer will be compared against the aggregate free space created by the requested filesystem configuration.

The following keywords provide descriptive information about the archive as a whole. They are generally used to assist the user in archive selection and to aid in archive management. These keywords are all optional and are used by the deployment programs only to assist the user in distinguishing between individual archives.

`creation_date`

The value of the `creation_date` keyword is a textual timestamp representing the time of creation for the archive. The value of this keyword can be overridden at archive creation time through the `flarcreate(1M)`. The timestamp must be in ISO-8601 complete basic calendar format without the time designator (ISO-8601, §5.4.1(a)) as follows:

```
CCYYMMDDhhmmss
```

For example:

```
20000131221409  
(January 31st, 2000 10:14:09pm)
```

The date and time included in the value should be in GMT.

`creation_master`

The value of the `creation_master` keyword is the name of the master machine used to create the archive. The value can be overridden at archive creation time.

`content_name`

The value of the `content_name` keyword should describe the archive's function and purpose. It is similar to the `NAME` parameter found in Solaris packages.

The value of the `content_name` keyword is used by the deployment utilities to identify the archive and can be presented to the user during the archive selection process and/or the extraction process. The value must be no longer than 256 characters.

`content_type`

The value of this keyword specifies a category for the archive. This category is defined by the user and is used by deployment software for display purposes. This keyword is the flash analog of the Solaris packaging `CATEGORY` keyword.

`content_description`

The value of this keyword is used to provide the user with a description of what the archive contains and should build on the description provided in `content_name`. In this respect, `content_description` is analogous to the `DESC` keyword used in Solaris packages.

There is no length limit to the value of `content_description`. To facilitate display, the value can contain escaped newline characters. As in C, the escaped newline takes the form of `\n`. Due to the escaped newline, backslashes must be included as `\\`. The description is displayed in a non-proportional font, with at least 40 characters available per line. Lines too long for display are wrapped.

`content_author`

The value of this keyword is a user-defined string identifying the creator of the archive. Suggested values include the full name of the creator, the creator's email address, or both.

`content_architectures`

The value of this keyword is a comma-delimited list of the kernel architectures supported by the given archive. The value of this keyword is generated at archive creation time, and can be overridden by the user at that time. If this keyword is present in the archive, the extraction mechanism validates the kernel architecture of the clone system with the list of architectures supported by the archive. The extraction fails if the kernel architecture of the clone is not supported by the archive. If the keyword is not present, no architecture validation is performed.

User-Defined Sections

Following the identification section may be zero or more user-defined sections. These sections are not processed by the archive extraction code and can be used for any purpose.

User-defined sections must be line-oriented, terminated with newline (ASCII 0x0a) characters. There is no limit on the length of individual lines. If binary data is to be included in a user-defined section, it should be encoded using base64 or a similar algorithm.

Archive Files Section

The archive files section contains the files gathered from the master system. While the length of this section should be the same as the value of the `files_archived_size` keyword in the identification section, you should not assume that these two values are equal. This section begins with `section_begin=archive`, but it does not have an ending section boundary.

NAME	format.dat – disk drive configuration for the format command
DESCRIPTION	<p>format .dat enables you to use your specific disk drives with <code>format(1M)</code>. On Solaris 2.3 and compatible systems, <code>format</code> will automatically configure and label SCSI drives, so that they need not be defined in <code>format .dat</code>. Three things can be defined in the data file:</p> <ul style="list-style-type: none"> ■ search paths ■ disk types ■ partition tables.
Syntax	<p>The following syntax rules apply to the data file:</p> <ul style="list-style-type: none"> ■ The pound # sign is the comment character. Any text on a line after a pound sign is not interpreted by <code>format</code>. ■ Each definition in the <code>format .dat</code> file appears on a single logical line. If the definition is more than one line long, all but the last line of the definition must end with a backslash (\). ■ A definition consists of a series of assignments that have an identifier on the left side and one or more values on the right side. The assignment operator is the equal sign (=). Assignments within a definition must be separated by a colon (:). ■ White space is ignored by <code>format(1M)</code>. If you want an assigned value to contain white space, enclose the entire value in double quotes ("). This will cause the white space within quotes to be preserved as part of the assignment value. ■ Some assignments can have multiple values on the right hand side. Separate values by a comma (,).
Keywords	<p>The data file contains disk definitions that are read in by <code>format(1M)</code> when it starts up. Each definition starts with one of the following keywords: <code>search_path</code>, <code>disk_type</code>, and <code>partition</code>.</p> <p><code>search_path</code> 4.x: Tells <code>format</code> which disks it should search for when it starts up. The list in the default data file contains all the disks in the GENERIC configuration file. If your system has disks that are not in the GENERIC configuration file, add them to the <code>search_path</code> definition in your data file. The data file can contain only one <code>search_path</code> definition. However, this single definition lets you specify all the disks you have in your system.</p> <p>5.x: By default, <code>format(1M)</code> understands all the logical devices that are of the form <code>/dev/rdisk/cntndnsn</code>; hence <code>search_path</code> is not normally defined on a 5.x system.</p> <p><code>disk_type</code> Defines the controller and disk model. Each <code>disk_type</code> definition contains information concerning the physical geometry of the disk. The default data file contains definitions for the controllers and disks that the Solaris operating environment supports. You need to</p>

add a new `disk_type` only if you have an unsupported disk. You can add as many `disk_type` definitions to the data file as you want.

The following controller types are supported by `format(1M)`:

XY450	Xylogics 450 controller (SMD)
XD7053	Xylogics 7053 controller (SMD)
SCSI	True SCSI (CCS or SCSI-2)
ISP-80	IPI panther controller

The keyword itself is assigned the name of the disk type. This name appears in the disk's label and is used to identify the disk type whenever `format(1M)` is run. Enclose the name in double quotes to preserve any white space in the name.

Below are lists of identifiers for supported controllers. Note that an asterisk (*) indicates the identifier is mandatory for that controller -- it is not part of the keyword name.

The following identifiers are assigned values in all `disk_type` definitions:

<code>acyl*</code>	alternate cylinders
<code>asect</code>	alternate sectors per track
<code>atrks</code>	alternate tracks
<code>fmt_time</code>	formatting time per cylinder
<code>ncyl*</code>	number of logical cylinders
<code>nhead*</code>	number of logical heads
<code>nsect*</code>	number of logical sectors per track
<code>pcyl*</code>	number of physical cylinders
<code>phead</code>	number of physical heads
<code>psect</code>	number of physical sectors per track
<code>rpm*</code>	drive RPM

These identifiers are for SCSI and MD-21 Controllers

<code>read_retries</code>	page 1 byte 3 (read retries)
<code>write_retries</code>	page 1 byte 8 (write retries)
<code>cyl_skew</code>	page 3 bytes 18-19 (cylinder skew)

trk_skew page 3 bytes 16-17 (track skew)
 trks_zone page 3 bytes 2-3 (tracks per zone)
 cache page 38 byte 2 (cache parameter)
 prefetch page 38 byte 3 (prefetch parameter)
 max_prefetch page 38 byte 4 (minimum prefetch)
 min_prefetch page 38 byte 6 (maximum prefetch)

Note: The Page 38 values are device-specific. Refer the user to the particular disk's manual for these values.

For SCSI disks, the following geometry specifiers may cause a mode select on the byte(s) indicated:

asect page 3 bytes 4-5 (alternate sectors per zone)
 atrks page 3 bytes 8-9 (alt. tracks per logical unit)
 phead page 4 byte 5 (number of heads)
 psect page 3 bytes 10-11 (sectors per track)

And these identifiers are for SMD Controllers Only

bps* bytes per sector (SMD)
 bpt* bytes per track (SMD)

Note: under SunOS 5.x, bpt is only required for SMD disks. Under SunOS 4.x, bpt was required for all disk types, even though it was only used for SMD disks.

And this identifier is for XY450 SMD Controllers Only

drive_type* drive type (SMD) (just call this "xy450 drive type")

partition

Defines a partition table for a specific disk type. The partition table contains the partitioning information, plus a name that lets you refer to it in `format(1M)`. The default data file contains default partition definitions for several kinds of disk drives. Add a partition definition if you repartitioned any of the disks on your system. Add as many partition definitions to the data file as you need.

Partition naming conventions differ in SunOS 4.x and in SunOS 5.x.

4.x: the partitions are named as a, b, c, d, e, f, g, h.

5.x: the partitions are referred to by numbers 0, 1, 2, 3, 4, 5, 6, 7.

format.dat(4)

EXAMPLES **EXAMPLE 1** A sample `disk_type` and partition.

Following is a sample `disk_type` and partition definition in `format.dat` file for SUN0535 disk device.

```
disk_type = "SUN0535" \  
: ctrl = SCSI : fmt_time = 4 \  
: ncyl = 1866 : acyl = 2 : pcyl = 2500 : nhead = 7 : nsect = 80 \  
: rpm = 5400  
partition = "SUN0535" \  
: disk = "SUN0535" : ctrl = SCSI \  
: 0 = 0, 64400 : 1 = 115, 103600 : 2 = 0, 1044960 : 6 = 300, 876960
```

FILES `/etc/format.dat` default data file if `format -x` is not specified, nor is there a `format.dat` file in the current directory.

SEE ALSO `format(1M)`

System Administration Guide: Basic Administration

NAME	fspec – format specification in text files
DESCRIPTION	<p>It is sometimes convenient to maintain text files on the system with non-standard tabs, (tabs that are not set at every eighth column). Such files must generally be converted to a standard format, frequently by replacing all tabs with the appropriate number of spaces, before they can be processed by system commands. A format specification occurring in the first line of a text file specifies how tabs are to be expanded in the remainder of the file.</p> <p>A format specification consists of a sequence of parameters separated by blanks and surrounded by the brackets < : and : >. Each parameter consists of a keyletter, possibly followed immediately by a value. The following parameters are recognized:</p> <p><i>t</i> <i>tabs</i> The <i>t</i> parameter specifies the tab settings for the file. The value of <i>t</i> <i>tabs</i> must be one of the following:</p> <ul style="list-style-type: none"> ■ A list of column numbers separated by commas, indicating tabs set at the specified columns. ■ A '-' followed immediately by an integer <i>n</i>, indicating tabs at intervals of <i>n</i> columns. ■ A '-' followed by the name of a "canned" tab specification. <p>Standard tabs are specified by <i>t</i>-8, or equivalently, <i>t</i>1, 9, 17, 25, etc. The canned tabs that are recognized are defined by the <i>t</i>abs(1) command.</p> <p><i>s</i> <i>size</i> The <i>s</i> parameter specifies a maximum line size. The value of <i>s</i> <i>size</i> must be an integer. Size checking is performed after tabs have been expanded, but before the margin is prepended.</p> <p><i>m</i> <i>margin</i> The <i>m</i> parameter specifies a number of spaces to be prepended to each line. The value of <i>m</i> <i>margin</i> must be an integer.</p> <p><i>d</i> The <i>d</i> parameter takes no value. Its presence indicates that the line containing the format specification is to be deleted from the converted file.</p> <p><i>e</i> The <i>e</i> parameter takes no value. Its presence indicates that the current format is to prevail only until another format specification is encountered in the file.</p> <p>Default values, which are assumed for parameters not supplied, are <i>t</i>-8 and <i>m</i>0. If the <i>s</i> parameter is not specified, no size checking is performed. If the first line of a file does not contain a format specification, the above defaults are assumed for the entire file. The following is an example of a line containing a format specification:</p> <pre>* <:t5,10,15 s72:> *</pre> <p>If a format specification can be disguised as a comment, it is not necessary to code the <i>d</i> parameter.</p>

NAME	<code>fstypes</code> – file that registers distributed file system packages
DESCRIPTION	<p><code>fstypes</code> resides in directory <code>/etc/dfs</code> and lists distributed file system utilities packages installed on the system. For each installed distributed file system type, there is a line that begins with the file system type name (for example, “<code>nfs</code>”), followed by white space and descriptive text.</p> <p>The file system indicated in the first line of the file is the default file system; when Distributed File System (DFS) Administration commands are entered without the option <code>-F fstypes</code>, the system takes the file system type from the first line of the <code>fstypes</code> file.</p> <p>The default file system can be changed by editing the <code>fstypes</code> file with any supported text editor.</p>
SEE ALSO	<code>dfmounts(1M)</code> , <code>dfshares(1M)</code> , <code>share(1M)</code> , <code>shareall(1M)</code> , <code>unshare(1M)</code>

fs_ufs(4)

NAME	fs_ufs, inode_ufs, inode – format of a ufs file system volume
SYNOPSIS	<pre>#include <sys/param.h> #include <sys/types.h> #include <sys/fs/ufs_fs.h> #include <sys/fs/ufs_inode.h></pre>
DESCRIPTION	<p>Standard UFS file system storage volumes have a common format for certain vital information. Every volume is divided into a certain number of blocks. The block size is a parameter of the file system. Sectors 0 to 15 contain primary and secondary bootstrapping programs.</p> <p>The actual file system begins at sector 16 with the super-block. The layout of the super-block is defined by the header <code><sys/fs/ufs_fs.h></code>.</p> <p>Each disk drive contains some number of file systems. A file system consists of a number of cylinder groups. Each cylinder group has inodes and data.</p> <p>A file system is described by its super-block, and by the information in the cylinder group blocks. The super-block is critical data and is replicated before each cylinder group block to protect against catastrophic loss. This is done at file system creation time and the critical super-block data does not change, so the copies need not be referenced.</p>
fs_clean	<p><code>fs_clean</code> indicates the state of the file system. The <code>FSCLEAN</code> state indicates an undamaged, cleanly unmounted file system. The <code>FSACTIVE</code> state indicates a mounted file system that has been updated. The <code>FSSTABLE</code> state indicates an idle mounted file system. The <code>FSFIX</code> state indicates that this fs is mounted, contains inconsistent file system data and is being repaired by <code>fsck</code>. The <code>FSBAD</code> state indicates that this file system contains inconsistent file system data. It is not necessary to run <code>fsck</code> on any unmounted file systems with a state of <code>FSCLEAN</code> or <code>FSSTABLE</code>. <code>mount(2)</code> will return <code>ENOSPC</code> if a UFS file system with a state of <code>FSACTIVE</code> is being mounted for read-write.</p> <p>To provide additional safeguard, <code>fs_clean</code> could be trusted only if <code>fs_state</code> contains a value equal to <code>FSOKAY - fs_time</code>, where <code>FSOKAY</code> is a constant integer. Otherwise, <code>fs_clean</code> is treated as though it contains the value of <code>FSACTIVE</code>.</p> <p>Addresses stored in inodes are capable of addressing fragments of "blocks." File system blocks of at most, size <code>MAXBSIZE</code> can be optionally broken into 2, 4, or 8 pieces, each of which is addressable; these pieces may be <code>DEV_BSIZE</code> or some multiple of a <code>DEV_BSIZE</code> unit.</p> <p>Large files consist exclusively of large data blocks. To avoid undue wasted disk space, the last data block of a small file is allocated only as many fragments of a large block as are necessary. The file system format retains only a single pointer to such a fragment, which is a piece of a single large block that has been divided. The size of</p>

such a fragment is determinable from information in the inode, using the `blksize(fs, ip, lbn)` macro.

The file system records space availability at the fragment level; aligned fragments are examined to determine block availability.

The root inode is the root of the file system. Inode 0 cannot be used for normal purposes and historically, bad blocks were linked to inode 1. Thus the root inode is 2 (inode 1 is no longer used for this purpose; however numerous dump tapes make this assumption, so we are stuck with it). The *lost+found* directory is given the next available inode when it is initially created by `mkfs(1M)`.

fs_minfree `fs_minfree` gives the minimum acceptable percentage of file system blocks which may be free. If the freelist drops below this level only the super-user may continue to allocate blocks. `fs_minfree` may be set to 0 if no reserve of free blocks is deemed necessary, however severe performance degradations will be observed if the file system is run at greater than 90% full; thus the default value of `fs_minfree` is 10%.

Empirically the best trade-off between block fragmentation and overall disk utilization at a loading of 90% comes with a fragmentation of 8; thus the default fragment size is an eighth of the block size.

fs_optim `fs_optim` specifies whether the file system should try to minimize the time spent allocating blocks, or if it should attempt to minimize the space fragmentation on the disk. If the value of `fs_minfree` is less than 10%, then the file system defaults to optimizing for space to avoid running out of full sized blocks. If the value of `fs_minfree` is greater than or equal to 10%, fragmentation is unlikely to be problematical, and the file system defaults to optimizing for time.

Cylinder group related limits: Each cylinder keeps track of the availability of blocks at different rotational positions, so that sequential blocks can be laid out with minimum rotational latency. `fs_nrpos` is the number of rotational positions which are distinguished. With the default `fs_nrpos` of 8, the resolution of the summary information is 2ms for a typical 3600 rpm drive.

fs_rotdelay `fs_rotdelay` gives the minimum number of milliseconds to initiate another disk transfer on the same cylinder. It is used in determining the rotationally optimal layout for disk blocks within a file; the default value for `fs_rotdelay` varies from drive to drive (see `tunefs(1M)`).

fs_maxcontig `fs_maxcontig` gives the maximum number of blocks, belonging to one file, that will be allocated contiguously before inserting a rotational delay.

Each file system has a statically allocated number of inodes. An inode is allocated for each NBPI bytes of disk space. The inode allocation strategy is extremely conservative.

MINBSIZE is the smallest allowable block size. With a MINBSIZE of 4096 it is possible to create files of size 2^{32} with only two levels of indirection. MINBSIZE must be large

fs_ufs(4)

enough to hold a cylinder group block, thus changes to `(struct cg)` must keep its size within `MINBSIZE`. Note: super-blocks are never more than size `SBSIZE`.

The path name on which the file system is mounted is maintained in `fs_fsmnt`. `MAXMNTLEN` defines the amount of space allocated in the super-block for this name.

The limit on the amount of summary information per file system is defined by `MAXCSBUFS`. It is currently parameterized for a maximum of two million cylinders.

Per cylinder group information is summarized in blocks allocated from the first cylinder group's data blocks. These blocks are read in from `fs_csaddr` (size `fs_cssize`) in addition to the super-block.

Note: `sizeof (struct csum)` must be a power of two in order for the `fs_cs` macro to work.

The inode is the focus of all file activity in the file system. There is a unique inode allocated for each active file, each current directory, each mounted-on file, text file, and the root. An inode is "named" by its device/i-number pair. For further information, see the header `<sys/fs/ufs_inode.h>`.

NAME	ftppaccess – FTP Server configuration file
SYNOPSIS	<code>/etc/ftpd/ftppaccess</code>
DESCRIPTION	The <code>ftppaccess</code> file is used to configure the operation of the FTP Server.
Access Capabilities	<p>The following access capabilities are supported:</p> <p><code>autogroup <i>groupname</i> <i>class</i> [<i>class</i>...]</code> If an <i>anonymous</i> user is a member of any of <i>class</i>, the FTP Server will perform a <code>setegid(2)</code> to <i>groupname</i>. This allows access to group and owner read-only files and directories to a particular class of anonymous users. <i>groupname</i> is a valid group returned by <code>getgrnam(3C)</code>.</p> <p><code>class <i>class</i> <i>typelist</i> <i>addrglob</i> [<i>addrglob</i>...]</code> Define <i>class</i> of users, with source addresses of the form <i>addrglob</i>. Multiple members of <i>class</i> may be defined. There may be multiple <code>class</code> commands listing additional members of the class. If multiple <code>class</code> commands can apply to the current session, the first one listed in the access file is used. If a valid class for a host is not defined, access will be denied. <i>typelist</i> is a comma-separated list of any of the keywords <i>anonymous</i>, <i>guest</i>, and <i>real</i>. If the <i>real</i> keyword is included, the class can match users using FTP to access real accounts. If the <i>anonymous</i> keyword is included the class can match users using anonymous FTP. The <i>guest</i> keyword matches guest access accounts.</p> <p><i>addrglob</i> may be a globbed domain name or a globbed numeric IPv4 address. It may also be the name of a file, starting with a slash (<code>/</code>), which contains additional address globs. IPv4 numeric addresses may also be specified in the form <code>address:netmask</code> or <code>address/CIDR</code>. IPv6 numeric addresses can only be specified with an optional CIDR, not using globs or netmasks.</p> <p>Placing an exclamation (!) before an <i>addrglob</i> negates the test. For example,</p> <pre>class rmtuser real !*.example.com</pre> <p>will classify real users from outside the <code>example.com</code> domain as the class <code>rmtuser</code>. Use care with this option. Remember, the result of each test is OR'ed with other tests on the line.</p> <p><code>deny <i>addrglob</i> [<i>message_file</i>]</code> Deny access to host(s) that match <i>addrglob</i> and display <i>message_file</i>. If the value of <i>addrglob</i> is <code>!nameserved</code> access to sites without a working nameservers is denied. <i>message_file</i> may contain magic cookies. See <code>message</code> for more details.</p> <p><code>guestgroup <i>groupname</i> [<i>groupname</i>...]</code> <code>guestuser <i>username</i> [<i>username</i>...]</code> <code>realgroup <i>groupname</i> [<i>groupname</i>...]</code> <code>realuser <i>username</i> [<i>username</i>...]</code> For <code>guestgroup</code>, if a <i>real</i> user is a member of any <i>groupname</i>, the session is set up like anonymous FTP. <i>groupname</i> is a valid group returned by <code>getgrnam(3C)</code>. The user's home directory must be set up exactly as anonymous FTP would be. The</p>

ftppaccess(4)

home directory field of the passwd entry is divided into two directories. The first field is the root directory that will be the argument to the `chroot(2)` call. The second field is the user's home directory, relative to the root directory. Use a `"/./"` to separate the two fields. For example, the following is the real entry in `/etc/passwd`:

```
guest1:x:100:92:Guest FTP:/export/home/guests/./guest1:/bin/true
```

When `guest1` successfully logs in, the FTP Server will `chroot()` to `/export/home/guests` and then `chdir(2)` to `/guest1`. The guest user will only be able to access the directory structure under `/export/home/guests`, which will look and act as `/` to `guest1`, just as an anonymous FTP user would. The `-d` option to `ftpconfig(1M)` is useful when creating guest FTP user accounts. The group name may be specified by either name or numeric ID. To use a numeric group ID, place a `'%'` before the number. You can give ranges. Use an asterisk to indicate all groups. `guestuser` works like `guestgroup`, except that it uses the user name or numeric ID. `realuser` and `realgroup` have the same syntax, but they reverse the effect of `guestuser` and `guestgroup`. They allow real user access when the remote user would otherwise be determined a guest.

```
guestuser *
realgroup admin
```

causes all non-anonymous users to be treated as guest, with the sole exception of users in the `admin` group, who are granted real user access.

`nice nice-delta [class]`

Adjust the process `nice` value of the FTP server process by the indicated `nice-delta` value if the remote user is a member of the named `class`. If `class` is not specified, then use `nice-delta` as the default adjustment to the FTP server process `nice` value. This default `nice` value adjustment is used to adjust the `nice` value of the server process only for those users who do not belong to any class for which a class-specific `nice` directive exists in the `ftppaccess` file.

`defumask umask [class]`

Set the `umask` applied to files created by the FTP server if the remote user is a member of the named class. If `class` is not specified, then use the `umask` as the default for classes that do not have one specified.. The mode of files created may be specified by using the `upload` directive.

`tcpwindow size [class]`

Set the TCP window size (socket buffer size) for the data connection. Use this to control network traffic. For instance, slow PPP dialin links may need smaller TCP windows to speed up throughput. If you do not know what this does, do not set it.

`keepalive yes|no`

Set the TCP `SO_KEEPALIVE` option for control and data sockets. This can be used to control network disconnect. If `yes`, then set it. If `no`, then use the system default (usually off). You probably want to set this.

timeout accept *seconds*
 timeout connect *seconds*
 timeout data *seconds*
 timeout idle *seconds*
 timeout maxidle *seconds*
 timeout RFC931 *seconds*

Set various timeout conditions.

- accept How long the FTP Server will wait for an incoming (PASV) data connection. The default is 120 seconds.
- connect How long the FTP Server will wait attempting to establish an outgoing (PORT) data connection. This effects the actual connection attempt. The daemon makes several attempts, sleeping between each attempt, before giving up. The default is 120 seconds.
- data How long the FTP Server will wait for some activity on the data connection. You should keep this long because the remote client may have a slow link, and there can be quite a bit of data queued for the client. The default is 1200 seconds.
- idle How long the FTP Server will wait for the next command. The default is 900 seconds. The default can also be overridden by using the `-t` option at the command-line. This access clause overrides both.
- maxidle The `SITE IDLE` command allows the remote client to establish a higher value for the idle timeout. The `maxidle` clause sets the upper limit that the client may request. The default can also be overridden by using the `-T` option at the command-line. This access clause overrides both. The default is 7200 seconds.
- RFC931 The maximum time the FTP server allows for the entire RFC931 (AUTH/ident) conversation. Setting this to zero (0) disables the server's use of this protocol. The information obtained by means of RFC931 is recorded in the system logs and is not actually used in any authentication. The default is 10 seconds.

`file-limit [raw] in|out|total count [class]`

Limit the number of data files a user in the given class may transfer. The limit may be placed on files *in*, *out*, or *total*. If no class is specified, the limit is the default for classes which do not have a limit specified. The optional parameter *raw* applies the limit to the total traffic rather than just data files.

`data-limit [raw] in|out|total count [class]`

Limit the number of data bytes a user in the given class may transfer. The limit may be placed on bytes *in*, *out*, or *total*. If no class is specified, the limit is the default for classes which do not have a limit specified. Note that once it has been exceeded, this limit will prevent transfers, but it will not terminate a transfer in progress. The optional parameter *raw* applies the limit to total traffic rather than just data files.

ftppaccess(4)

`limit-time` *|*anonymous*|*guest* *minutes*

Limit the total time a session can take. By default, there is no limit. Real users are never limited.

`guestserver` [*hostname*...]

Control which hosts may be used for anonymous access. If used without *hostname*, all anonymous access is denied to this site. More than one *hostname* may be specified. Anonymous access will only be allowed on the named machines. If access is denied, the user will be asked to use the first *hostname* listed.

`limit class n times` [*message_file*]

Limit *class* to *n* users at times *times*, displaying *message_file* if the user is denied access. A `limit` check is performed at login time only. If multiple `limit` commands can apply to the current session, the first applicable one is used. Failing to define a valid limit, or a limit of -1, is equivalent to no limits. The format of *times* is ;:

```
day [day . . .] [time-range] [ [day [day . . .] [time-range]] . . .
```

The value of *day* can be *Su*, *Mo*, *Tu*, *We*, *Th*, *Fr*, *Sa*, *Wk* (for any weekday Monday through Friday), or *Any*. *time-range* is in 24-hour clock notation. If a time range is not specified, any time of the day is matched. Multiple *day* and *time-range* may be specified by the “|” symbol. For example, `Wk1730-0900|Sa|Su` specifies 5:30 p.m. to 9:00 a.m., Monday through Friday, and anytime on weekends. *message_file* may contain magic cookies. See `message` for more details.

`noretrieve` [*absolute*|*relative*]

[*class=classname*...][*-*] *filename* [*filename*...]

Always deny retrievability of these files. If *filename* specifies a pathname that begins with ‘/’ character, then only those files are marked no retrieve. Otherwise all files that match the *filename* are refused transfer. For example, `noretrieve /etc/passwd core` specifies no one will be able to retrieve the `/etc/passwd` file. You will be allowed to transfer any file named `passwd` that is not in `/etc`.

On the other hand, no one will be able to get files named `core`, wherever they are. Directory specifications mark all files and subdirectories in the named directory unretrievable. The *filename* may be specified as a file glob. For example,

```
noretrieve /etc /home/*/.htaccess
```

specifies that no files in `/etc` or any of its subdirectories may be retrieved. Also, no files named `.htaccess` anywhere under the `/home` directory may be retrieved. The optional first parameter selects whether names are interpreted as absolute or relative to the current `chroot'd` environment. The default is to interpret names beginning with a slash as absolute. The `noretrieve` restrictions may be placed upon members of particular classes. If any `class=` is specified, the named files cannot be retrieved only if the current user is a member of one of the given classes.

`allow-retrieve` [*absolute*|*relative*]

[*class=classname*...][*-*] *filename* [*filename*...]

Allows retrieval of files which would otherwise be denied by noretrieve.

`loginfails` *number*

After *number* login failures, log a "repeated login failures" message and terminate the FTP connection. The default value for *number* is 5.

`private` *yes* | *no*

Allow or deny use of the `SITE GROUP` and `SITE GPASS` commands after the user logs in. The `SITE GROUP` and `SITE GPASS` commands specify an enhanced access group and associated password. If the group name and password are valid, the user becomes a member of the group specified in the group access file `/etc/ftpd/ftpgroups` by means of `setegid(2)`. See `ftpgroups(4)` for the format of the file. For this option to work for anonymous FTP users, the FTP Server must keep `/etc/group` permanently open and load the group access file into memory. This means that the FTP Server now has an additional file descriptor open, and the necessary passwords and access privileges granted to users by means of `SITE GROUP` will be static for the duration of an FTP session. If you have an urgent need to change the access groups or passwords now, you have to kill all of the running FTP Servers.

Informational Capabilities

The following informational capabilities are supported:

`greeting` *full* | *brief* | *terse*

`greeting` *text* *message*

The greeting command allows you to control how much information is given out before the remote user logs in. `greeting full`, which is the default greeting, shows the hostname and daemon version. `greeting brief` shows the hostname. `greeting terse` simply says "FTP Server ready." Although `full` is the default, `brief` is suggested.

The `text` form allows you to specify any greeting message. *message* can be any string. Whitespace (spaces and tabs) is converted to a single space.

`banner` *path*

The banner command operates similarly to the `message` command, except that the banner is displayed before the user enters the username. The *path* is relative to the real system root, not to the base of the anonymous FTP directory.

Use of the `banner` command can completely prevent non-compliant FTP clients from making use of the FTP Server. Not all clients can handle multi-line responses, which is how the banner is displayed.

`email` *name*

Use this command to define the email address for the FTP Server administrator. This string will be printed every time the `%E` magic cookie is used in message files.

`hostname` *some.host.name*

Defines the default host name of the FTP Server. This string will be printed on the greeting message and every time the `%L` magic cookie is used. The host name for

ftppaccess(4)

virtual servers overrides this value. If no host name is specified, the default host name for the local machine is used.

message *path* [*when* [*class*...]]

Define a file with *path* such that the FTP Server will display the contents of the file to the user at login time or upon using the change working directory command. The *when* parameter may be LOGIN or CWD=*dirglob*. If *when* is CWD=*dirglob*, *dirglob* specifies the new default directory that will trigger the notification. A *dirglob* of "*" matches all directories.

The optional *class* specification allows the message to be displayed only to members of a particular class. More than one class may be specified.

"Magic cookies" can be present in *path* that cause the FTP Server to replace the cookie with a specified text string:

%T	Local time. For example, Thu Nov 15 17:12:42 1990.
%F	Free space in partition of CWD, in Kbytes.
%C	Current working directory.
%E	The email address for the FTP Server administrator.
%R	Remote host name.
%L	Local host name.
%U	Username given at login time.
%u	Username as defined by means of RFC 931 authentication.
%M	Maximum allowed number of users in this class.
%N	Current number of users in this class.

The message is displayed only once to avoid annoying the user. Remember that when messages are triggered by an anonymous or guest FTP user, they must be relative to the base of the anonymous or guest FTP directory tree.

readme *pathglob* [*when* [*class*...]]

Define a file with *pathglob* such that the FTP Server will notify the user at login time or upon using the change working directory command that the file exists and the date that it was modified. The *when* parameter may be LOGIN or CWD=*dirglob*. If *when* is CWD=*dirglob*, *dirglob* specifies the new default directory that will trigger the notification. A *dirglob* of "*" matches all directories. The message will only be displayed once, to avoid bothering users. Remember that when README messages are triggered by an anonymous or guest FTP user, the *pathglob* must be relative to the base of the anonymous or guest FTP directory tree.

The optional *class* specification allows the message to be displayed only to members of a particular class. You can specify more than one class.

Logging Capabilities

The following logging capabilities are supported:

log commands *typelist*

Enables logging of the individual FTP commands sent by users. *typelist* is a comma-separated list of any of the keywords *anonymous*, *guest*, and *real*. Command logging information is written to the system log.

log transfers *typelist directions*

Log file transfers made by FTP users to the *xferlog*(4) file. Logging of incoming transfers to the server can be enabled separately from outbound transfers from the server. *directions* is a comma-separated list of any of the two keywords *inbound* and *outbound*, and will respectively cause transfers to be logged for files sent to and from the server.

log security *typelist*

Enables logging of violations of security rules to the system log, including for example, *notretrieve* and *.notar*.

log syslog**log syslog+xferlog**

Redirect the logging messages for incoming and outgoing transfers to *syslog*. Without this option the messages are written to *xferlog*. When you specify *syslog+xferlog*, the transfer log messages are sent to both the system log file and the *xferlog* file.

Miscellaneous Capabilities

The following miscellaneous capabilities are supported:

alias *string dir*

Define an alias, *string*, for a directory. Use this command to add the concept of logical directories. For example: `alias rfc: /pub/doc/rfc` would allow the user to access `/pub/doc/rfc` from any directory by the command "`cd rfc:`". Aliases only apply to the `cd` command.

cdpath *dir*

Define an entry in the *cdpath*. This command defines a search path that is used when changing directories. For example:

```
cdpath /pub/packages
cdpath /.aliases
```

would allow the user to move into any directory directly under either the `/pub/packages` or the `/.aliases` directories. The search path is defined by the order in which the lines appear in the *ftppaccess* file. If the user were to give the command `ftp> cd foo` the directory will be searched for in the following order:

```
./foo
an alias called foo
/pub/packages/foo
/.aliases/foo
```

The *cdpath* is only available with the `cd` command. If you have a large number of aliases, you might want to set up an *aliases* directory with links to all of the areas you wish to make available to users.

ftppass(4)

`compress` *yes* | *no* *classglob* [*classglob*...]

`tar` *yes* | *no* *classglob* [*classglob*...]

Enable the use of conversions marked with the `O_COMPRESS`, `O_UNCOMPRESS`, and `O_TAR` options in `/etc/ftpd/ftpconversions`. See `ftpconversions(4)`.

`shutdown` *path*

If the file pointed to by *path* exists, the server will check the file regularly to see if the server is going to be shut down. If a shutdown is planned, the user is notified. New connections are denied after a specified time before shutdown. Current connections are dropped at a specified time before shutdown.

The format of the file specified by *path* is:

year month day hour minute deny_offset disc_offset text

year A value of 1970 or greater.

month A value of 0 to 11.

day A value of 1 to 31.

hour A value of 0 to 23.

minute A value of 0 to 59.

deny_offset

disc_offset

The offsets in HHMM format that new connections will be denied and existing connections will be disconnected before the shutdown time.

text Follows the normal rules for any *message*. The following additional magic cookies are available:

%s The time at which the system is going to shut down.

%r The time at which new connections will be denied.

%d The time at which current connections will be dropped.

All times are in the form: `ddd MMM DD hh:mm:ss YYYY`. Only one `shutdown` command can be present in the configuration file. You can use the external program `ftpshtut(1M)` to automate generation of this file.

`daemonaddress` *address*

Listen only on the IP address specified. If the value is not set, then the FTP Server will listen for connections on every IP address. This applies only when the FTP Server is run in standalone mode.

`virtual` *address* *root* | *banner* | *logfile* *path*

Enable the FTP Server limited virtual hosting capabilities. The *address* is the IP address of the virtual server. The second argument specifies that the *path* is either the path to the *root* of the filesystem for this virtual server, the *banner* presented to the user when connecting to this virtual server, or the *logfile* where transfers are recorded for this virtual server. If the *logfile* is not specified the default log

file will be used. All other message files and permissions as well as any other settings in this file apply to all virtual servers. The *address* may also be specified as a hostname rather than as an IP number. This is strongly discouraged since, if DNS is not available at the time the FTP session begins, the hostname will not be matched.

`root | logfile path`

In contrast to limited virtual hosting, complete virtual hosting allows separate configuration files to be virtual host specific. See `ftpservers(4)`. The only additions that are necessary in a virtual host's `ftppaccess` file is the `root` directive that ensures the correct root directory is used for the virtual host. This only works with complete virtual hosting, which in contrast to limited virtual hosting, allows separate configuration files to be specified for each virtual host.

path is either the root of the filesystem for this virtual server or the logfile where transfers for this virtual server are recorded. `root` and `logfile` may only be specified when not preceded by `virtual address` in a virtual host's `ftppaccess` file.

`virtual address hostname | email string`

Set the hostname shown in the greeting message and status command, or the email address used in message files and on the HELP command, to the given *string*.

`virtual address allow username [username...]`

`virtual address deny username [username...]`

By default, real and guest users are not allowed to log in on the virtual server, unless they are guests that are chroot'd to the virtual root. The users listed on the `virtual allow` line(s) are granted access. You can grant access to all users by giving '*' as the *username*. The `virtual deny` clauses are processed after the `virtual allow` clauses. Thus specific users can be denied access although all users were allowed in an earlier clause.

`virtual address private`

Deny log in access to anonymous users on the virtual server. Anonymous users are generally allowed to log in on the virtual server if this option is not specified.

`virtual address passwd file`

Use a different `passwd` file for the virtual host.

`virtual address shadow file`

Use a different `shadow` file for the virtual host.

`defaultserver deny username [username...]`

`defaultserver allow username [username...]`

By default, all users are allowed access to the non-virtual FTP Server. Use `defaultserver deny` to revoke access for specific real and guest users. Specify '*' to deny access to all users, except anonymous users. Specific real and guest users can then be allowed access by using `defaultserver allow`.

`defaultserver private`

By default, all users are allowed access to the non-virtual FTP Server. Use `defaultserver private` to revoke access for anonymous users.

ftppaccess(4)

The `virtual` and `defaultserver` `allow`, `deny` and `private` clauses provide a means to control which users are allowed access to which FTP Servers.

`passive address externalip cidr`

Allow control of the address reported in response to a `passive` command. When any control connection matching `cidr` requests a passive data connection (PASV), the `externalip` address is reported. This does not change the address that the daemon actually listens on, only the address reported to the client. This feature allows the daemon to operate correctly behind IP renumbering firewalls. For example:

```
passive address 10.0.1.15 10.0.0.0/8
passive address 192.168.1.5 0.0.0.0/0
```

Clients connecting from the class-A network 10 will be told the passive connection is listening on IP address 10.0.1.15 while all others will be told the connection is listening on 192.168.1.5 Multiple passive addresses may be specified to handle complex, or multi-gatewayed, networks.

`passive ports cidr min max`

Allows control of the TCP port numbers which may be used for a passive data connection. If the control connection matches the `cidr`, a port in the range `min` to `max` will be randomly selected for the daemon to listen on. This feature allows firewalls to limit the ports that remote clients may use to connect into the protected network.

`cidr` is shorthand for an IP address followed by a slash and the number of left-most bits that represent the network address, as opposed to the machine address. For example, if you are using the reserved class-A network 10, instead of a netmask of 255.0.0.0, use a CIDR of /8, as in 10.0.0.0/8, to represent your network.

`pasv-allow class [addrglob...]`

`port-allow class [addrglob...]`

Normally, the FTP Server does not allow a `PORT` command to specify an address different than that of the control connection. Nor does it allow a PASV connection from another address.

The `port-allow` clause provides a list of addresses that the specified class of user may give on a `PORT` command. These addresses will be allowed even if they do not match the IP address of the client-side of the control connection.

The `pasv-allow` clause provides a list of addresses that the specified class of user may make data connections from. These addresses will be allowed even if they do not match the IP address of the client-side of the control connection.

`lslong command [options...]`

`lsshort command [options...]`

`lsplain command [options...]`

Use the `lslong`, `lsshort`, and `lsplain` clauses to specify the commands and options to use to generate directory listings. The options cannot contain spaces, and the default values for these clauses are generally correct. Use `lslong`, `lsshort`, or `lsplain` only if absolutely necessary.

`mailserver` *hostname*

Specify the name of a mail server that will accept upload notifications for the FTP Server. Multiple mail servers may be listed. The FTP Server will attempt to deliver the upload notification to each, in order, until one accepts the message. If no mail servers are specified, `localhost` is used. This option is only meaningful if anyone is to be notified of anonymous uploads. See `incmail`.

`incmail` *emailaddress*

`virtual` *address* `incmail` *emailaddress*

`defaultserver` `incmail` *emailaddress*

Specify email addresses to be notified of anonymous uploads. Multiple addresses can be specified. Each will receive a notification. If no addresses are specified, no notifications are sent.

If addresses are specified for a virtual host, only those addresses will be sent notification of anonymous uploads on that host. Otherwise, notifications will be sent to the global addresses.

`defaultserver` addresses only apply when the FTP session is not using one of the virtual hosts. In this way, you can receive notifications for your default anonymous area, but not see notifications to virtual hosts that do not have their own notifications.

`mailfrom` *emailaddress*

`virtual` *address* `mailfrom` *emailaddress*

`defaultserver` `mailfrom` *emailaddress*

Specify the sender's email address for anonymous upload notifications. Only one address may be specified. If no `mailfrom` applies, email is sent from the default mailbox name `wu-ftp`. To avoid problems if the recipient attempts to reply to a notification, or if downstream mail problems generate bounces, you should ensure the `mailfrom` address is deliverable.

Permission Capabilities

The following permission capabilities are supported:

`chmod` `yes|no` *typelist*

`delete` `yes|no` *typelist*

`overwrite` `yes|no` *typelist*

`rename` `yes|no` *typelist*

`umask` `yes|no` *typelist*

Allows or disallows the ability to perform the specified function. By default, all real and guest users are allowed. Anonymous users are only allowed `overwrite` and `umask`.

typelist is a comma-separated list of any of the keywords `anonymous`, `guest`, `real` and `class=`. When `class=` appears, it must be followed by a classname. If any `class=` appears, the *typelist* restriction applies only to users in that class.

`passwd-check` `none|trivial|rfc822` [`enforce|warn`]

Define the level and enforcement of password checking done by the FTP Server for anonymous FTP.

ftppass(4)

none	No password checking is performed.
trivial	The password must contain an '@'.
rfc822	The password must be <i>RFC 822</i> compliant.
warn	Warn, but permit the login.
enforce	Notify and deny the login.

deny-email *case-insensitive-emailaddress*

Consider the email address given as an argument as invalid. If `passwd-check` is set to `enforce`, anonymous users giving this address as a password cannot log in. That way, you can stop users from having stupid WWW browsers use fake addresses like `IE?0User@` or `mozilla@`. (by using this, you are not shutting out users using a WWW browser for ftp - you just make them configure their browser correctly.) Only one address is allowed per line, but you can have as many `deny-email` addresses as you like.

path-filter *typelist message allowed_regexp* [*disallowed_regexp...*]

For users in *typelist*, `path-filter` defines regular expressions that control what characters can be used in the filename of an uploaded file or created directory. There may be multiple disallowed regular expressions. If a filename is invalid due to failure to match the regular expression criteria, *message* will be displayed to the user. For example:

```
path-filter anonymous /etc/pathmsg ^[-A-Za-z0-9._]*$ ^\.\ ^-
```

specifies that all upload filenames for anonymous users must be made of only the characters A-Z, a-z, 0-9, and "._" and may not begin with a "." or "-". If the filename is invalid, `/etc/pathmsg` will be displayed to the user.

upload [*absolute|relative*] [*class=classname*]... [-] *root-dir dirglob* *yes|no* *owner group mode* [*dirs|nodirs*] [*d_mode*]

Define a directory with *dirglob* that permits or denies uploads. If it does permit uploads, all newly created files will be owned by *owner* and *group* and will have their permissions set according to *mode*. Existing files that are overwritten will retain their original ownership and permissions. Directories are matched on a best-match basis. For example:

```
upload /var/ftp * no
upload /var/ftp /incoming yes ftp daemon 0666
upload /var/ftp /incoming/gifs yes jlc guest 0600 nodirs
```

would only allow uploads into `/incoming` and `/incoming/gifs`. Files that were uploaded to `/incoming` are owned by `ftp/daemon` and have permissions of `0666`. Files uploaded to `/incoming/gifs` are owned by `jlc/guest` and have permissions of `0600`. The optional "`dirs`" and "`nodirs`" keywords can be specified to allow or disallow the creation of new subdirectories using the `mkdir` command. If the `upload` command is used, directory creation is allowed by default. To turn it

off by default, you must specify a user, group and mode followed by the "nodirs" keyword as the first line where the `upload` command is used in this file. If directories are permitted, the optional `d_mode` determines the permissions for a newly created directory. If `d_mode` is omitted, the permissions are inferred from `mode`. The permissions are 0777 if `mode` is also omitted. The `upload` keyword only applies to users who have a home directory of `root-dir`. `root-dir` may be specified as "*" to match any home directory. The `owner` or `group` may each be specified as "*", in which case any uploaded files or directories will be created with the ownership of the directory in which they are created. The optional first parameter selects whether `root-dir` names are interpreted as absolute or relative to the current `chroot 'd` environment. The default is to interpret `<root-dir>` names as absolute. You can specify any number of `class=classname` restrictions. If any are specified, this upload clause only takes effect if the current user is a member of one of the classes.

In the absence of any matching `upload` clause, real and guest users can upload files and make directories, but anonymous users cannot. The mode of uploaded files is 0666. For created directories, the mode is 0777. Both modes are modified by the current `umask` setting.

`throughput root-dir subdir-glob file-glob-list`

`bytes-per-second bytes-per-second-multiply remote-glob-list`

Define files by means of a comma-separated `file-glob-list` in `subdir` matched by `subdir-glob` under `root-dir` that have restricted transfer throughput of `bytes-per-second` on download when the remote hostname or remote IP address matches the comma-separated `remote-glob-list`. Entries are matched on a best-match basis. For example:

```
throughput /e/ftp * * oo - *
throughput /e/ftp /sw* * 1024 0.5 *
throughput /e/ftp /sw* README oo - *
throughput /e/ftp /sw* * oo - *.foo.com
```

would set maximum throughput per default, but restrict download to 1024 bytes per second for any files under `/e/ftp/sw/` that are not named `README`. The only exceptions are remote hosts from within the domain `foo.com` which always get maximum throughput. Every time a remote client has retrieved a file under `/e/ftp/sw/` the bytes per seconds of the matched entry line are internally multiplied by a factor, here 0.5. When the remote client retrieves its second file, it is served with 512 bytes per second, the third time with only 256 bytes per second, the fourth time with only 128 bytes per second, and so on. The string "oo" for the bytes per second field means no throughput restriction. A multiply factor of 1.0 or "-" means no change of the throughput after every successful transfer. The `root-dir` here must match the home directory specified in the password database. The `throughput` keyword only applies to users who have a home directory of `root-dir`.

`anonymous-root root-dir [class...]`

`root-dir` specifies the `chroot ()` path for anonymous users. If no `anonymous-root` is matched, the old method of parsing the home directory for the FTP user is used. If no `class` is specified, this is the root directory for anonymous users who do not

ftppaccess(4)

match any other anonymous-root specification. Multiple classes may be specified on this line. If an anonymous-root is chosen for the user, the FTP user's home directory in the *root-dir/etc/passwd* file is used to determine the initial directory and the FTP user's home directory in the system-wide */etc/passwd* is not used. For example:

```
anonymous-root /home/ftp
anonymous-root /home/localftp localnet
```

causes all anonymous users to be `chroot`'d to the directory */home/ftp*. If the FTP user exists in */home/ftp/etc/passwd*, their initial CWD is that home directory. Anonymous users in the class *localnet*, however, are `chroot`'d to the directory */home/localftp* and their initial CWD is taken from the FTP user's home directory in */home/localftp/etc/passwd*.

`guest-root root-dir [uid-range...]`

root-dir specifies the `chroot()` path for guest users. If no `guest-root` is matched, the old method of parsing the user's home directory is used. If no *uid-range* is specified, this is the root directory for guestusers who do not match any other `guest-root` specification. Multiple UID ranges may be given on this line. If a `guest-root` is chosen for the user, the user's home directory in the *root-dir/etc/passwd* file is used to determine the initial directory and the home directory in the system-wide */etc/passwd* is not used. *uid-range* specifies names or numeric UID values. To use numbers, put a % symbol before it or before the range. Ranges are specified by giving the lower and upper bounds (inclusive), separated by a dash. If the lower bound is omitted, it means "all up to." If the upper bound is omitted, it means "all starting from." For example:

```
guest-root /home/users
guest-root /home/staff %100-999 sally
guest-root /home/users/owner/ftp frank
```

causes all guest users to `chroot()` to */home/users* then starts each user in the user's home directory, as specified in */home/users/etc/passwd*. Users in the range 100 through 999, inclusive, and user *sally*, will be `chroot`'d to */home/staff* and the CWD will be taken from their entries in */home/staff/etc/passwd*. The single user *frank* will be `chroot`'d to */home/users/owner/ftp* and the CWD will be from his entry in */home/users/owner/ftp/etc/passwd*.

The order is important for both `anonymous-root` and `guest-root`. If a user would match multiple clauses, only the first applies; with the exception of the clause which has no *class* or *uid-range*, which applies only if no other clause matches.

`deny-uid uid-range [uid-range...]`

`deny-gid gid-range [gid-range...]`

`allow-uid uid-range [uid-range...]`

`allow-gid gid-range [gid-range...]`

Use these clauses to specify UID and GID values that will be denied access to the FTP Server. The `allow-uid` and `allow-gid` clauses may be used to allow access

for UID and GID values which would otherwise be denied. These checks occur before all others. `deny` is checked before `allow`. The default is to allow access. These clauses do not apply to anonymous users. Use `defaultserver private` to deny access to anonymous users. In most cases, these clauses obviate the need for an `ftpusers(4)` file. For example, the following clauses deny FTP Server access to all privileged or special users and groups, except the `guest1` user or group.

```
deny-gid %-99 nobody noaccess nogroup
deny-uid %-99 nobody noaccess nobody4
allow-gid guest1
allow-uid guest1
```

Support for the `ftpusers` file still exists, so it may be used when changing the `ftppaccess` file is not desired. In any place a single UID or GID is allowed throughout the `ftppaccess` file, either names or numbers also may be used. To use a number, put a `'%'` symbol before it. In places where a range is allowed, put the `'%'` before the range. A `"*"` matches all UIDs or GIDs.

```
restricted-uid uid-range [uid-range...]
restricted-gid gid-range [gid-range...]
unrestricted-uid uid-range [uid-range...]
unrestricted-gid gid-range [gid-range...]
```

These clauses control whether or not real or guest users will be allowed access to areas on the FTP site outside their home directories. These clauses are not meant to replace the use of `guestgroup` and `guestuser`. Instead, use these clauses to supplement the operation of guests. The `unrestricted-uid` and `unrestricted-gid` clauses may be used to allow users outside their home directories who would otherwise be restricted.

The following example shows the intended use for these clauses. Assume user `dick` has a home directory `/home/dick` and `jane` has a home directory `/home/jane`:

```
guest-root /home dick jane
restricted-uid dick jane
```

While both `dick` and `jane` are `chroot`'d to `/home`, they cannot access each other's files because they are restricted to their home directories. However, you should not rely solely upon the FTP restrictions to control access. As with all other FTP access rules, you should also use directory and file permissions to support the operation of the `ftppaccess` configuration.

```
site-exec-max-lines number [class...]
```

The `SITE EXEC` feature traditionally limits the number of lines of output that may be sent to the remote client. Use this clause to set this limit. If this clause is omitted, the limit is 20 lines. A limit of 0 (zero) implies no limit. Be very careful if you choose to remove the limit. If a clause is found matching the remote user's class, that limit is used. Otherwise, the clause with class `'*'`, or no class given, is used. For example:

```
site-exec-max-lines 200 remote
site-exec-max-lines 0 local
```

ftppaccess(4)

site-exec-max-lines 25

limits output from SITE EXEC (and therefore SITE INDEX) to 200 lines for remote users, specifies there is no limit at all for local users, and sets a limit of 25 lines for all other users.

dns refuse_mismatch *filename* [override]

Refuse FTP sessions when the forward and reverse lookups for the remote site do not match. Display the named file, like a message file, admonishing the user. If the optional override is specified, allow the connection after complaining.

dns refuse_no_reverse *filename* [override]

Refuse FTP sessions when there is no reverse DNS entry for the remote site. Display the named file, like a message file, admonishing the user. If the optional override is specified, allow the connection after complaining.

dns resolveroptions [options]

The dns resolveroptions option allows you to adjust name server options. The line takes a series of flags as documented in resolver(3resolv), with the leading RES_ removed. Each can be preceded by an optional + or -. For example:

```
dns resolveroptions +aaonly -dnsrc
```

turns on the aaonly option (only accept authoritative answers) and turns off the dnsrc option (search the domain path).

Lines that begin with a # sign are treated as comment lines and are ignored.

NAME	ftpconversions – FTP Server conversions database																						
SYNOPSIS	/etc/ftpd/ftpconversions																						
DESCRIPTION	<p>When the FTP Server, in <code>ftpd(1M)</code>, receives the retrieve (<code>RETR</code>) command, if the specified file does not exist, it looks for a conversion to change an existing file or directory of the same base name into the format requested, subject to the <code>ftppass(4)</code> <code>compress</code> and <code>tar</code> capabilities.</p> <p>The conversions and their attributes known by <code>in.ftpd(1M)</code> are stored in an ASCII file of the following format. Each line in the file provides a description for a single conversion. The fields in this file are separated by colons (:).</p> <pre>%s:%s:%s:%s:%s:%s:%s:%s 1 2 3 4 5 6 7 8</pre> <p>The fields are described as follows:</p> <table> <tr> <td>1</td> <td>Strip prefix.</td> </tr> <tr> <td>2</td> <td>Strip postfix.</td> </tr> <tr> <td>3</td> <td>Addon prefix.</td> </tr> <tr> <td>4</td> <td>Addon postfix.</td> </tr> <tr> <td>5</td> <td>External command.</td> </tr> <tr> <td>6</td> <td>Types.</td> </tr> <tr> <td>7</td> <td>Options.</td> </tr> <tr> <td>8</td> <td>Description.</td> </tr> </table> <p>The <code>Strip prefix</code> and <code>Addon prefix</code> fields are not currently supported.</p> <p>The <code>Strip postfix</code> and <code>addon postfix</code> fields are extensions to be added to or removed from the requested <code>filename</code> in attempting to produce the name of an existing file or directory. When the attempt succeeds, the FTP Server runs the external command associated with the conversion. The magic cookie <code>%s</code> in the argument is passed to the command, replaced with the name of the existing file or directory.</p> <p><code>External command</code> is the absolute pathname of a command to run followed by the appropriate options to carry out the conversion. The standard output of the command is sent back in response to the <code>RETR</code> (retrieve) command. For anonymous and guest users to be able to execute the command, it must be present in their <code>chroot'd</code> hierarchy along with any necessary dynamic libraries.</p> <p><code>Types</code> specifies the conversion type. The following values are recognized:</p> <table> <tr> <td><code>T_ASCII</code></td> <td>ASCII transfers are allowed of a file produced by the conversion.</td> </tr> <tr> <td><code>T_DIR</code></td> <td>Directories can be converted.</td> </tr> <tr> <td><code>T_REG</code></td> <td>Regular files can be converted.</td> </tr> </table>	1	Strip prefix.	2	Strip postfix.	3	Addon prefix.	4	Addon postfix.	5	External command.	6	Types.	7	Options.	8	Description.	<code>T_ASCII</code>	ASCII transfers are allowed of a file produced by the conversion.	<code>T_DIR</code>	Directories can be converted.	<code>T_REG</code>	Regular files can be converted.
1	Strip prefix.																						
2	Strip postfix.																						
3	Addon prefix.																						
4	Addon postfix.																						
5	External command.																						
6	Types.																						
7	Options.																						
8	Description.																						
<code>T_ASCII</code>	ASCII transfers are allowed of a file produced by the conversion.																						
<code>T_DIR</code>	Directories can be converted.																						
<code>T_REG</code>	Regular files can be converted.																						

ftpconversions(4)

Options are checked against the `ftppaccess(4)` `compress` and `tar` capabilities and are recorded in the `special-action-flag` field that is written to the FTP Server logfile. See `xferlog(4)`. The following options are supported:

`O_COMPRESS` conversion compresses
`O_TAR` conversion archives
`O_UNCOMPRESS` conversion uncompresses

You can specify more than one option by using "|" to separate options. For example, `O_TAR|O_COMPRESS` specifies that the conversion archives and compresses.

`Description` is a one word description of the conversion that is used in error messages returned to the FTP client.

Lines that begin with a # sign are treated as comment lines and are ignored.

EXAMPLES **EXAMPLE 1** Compressing a Regular File for Transfer

The following example specifies a conversion which generates `filename.Z` by compressing an existing file `filename`. The conversion can only be applied to regular files, not directories, and the absence of `T_ASCII` prevents the resulting file from being transferred in ASCII mode.

```
:.Z: : /usr/bin/compress -c %s:T_REG:O_COMPRESS:COMPRESS
```

EXAMPLE 2 Uncompressing and Transferring in ASCII Mode

The following example specifies a conversion that takes `filename.Z` and uncompresses it to produce `filename`, which then can be transferred in ASCII mode.

```
:.Z: : /usr/bin/compress -cd %s:T_REG|T_ASCII:O_UNCOMPRESS:UNCOMPRESS
```

NAME	ftpgroups – FTP Server enhanced group access file				
SYNOPSIS	/etc/ftpd/ftpgroups				
DESCRIPTION	<p>The ftpgroups file contains the enhanced group access information.</p> <p>After login, if the ftpaccess(4) file includes <i>private yes</i>, the user may use the SITE GROUP and SITE GPASS commands to specify an enhanced access group and a password for that group. If the access group name and password are valid, the the FTP Server executes setegid(2) to make the user a member of the real group listed in the ftpgroups file.</p> <p>The format for the ftpgroups file is:</p> <pre>accessgroup:encrypted_password:real_group_name</pre> <p>The fields are defined as follows:</p> <p><i>accessgroup</i> An arbitrary string of alphanumeric and punctuation characters.</p> <p><i>encrypted_password</i> The group password encrypted exactly like in /etc/shadow.</p> <p><i>real_group_name</i> The name of a valid group returned by getgrnam(3C).</p> <p>The privatepw utility is an administrative tool to add, delete and list enhanced access group information in the ftpgroups file. See privatepw(1M). Lines that begin with a # sign are treated as comment lines and are ignored.</p>

ftphosts(4)

NAME	ftphosts – FTP Server individual user host access file				
SYNOPSIS	/etc/ftpd/ftphosts				
DESCRIPTION	<p>The <code>ftphosts</code> file is used to allow or deny access to accounts from specified hosts. The following access capabilities are supported:</p> <pre>allow <i>username addrglob</i> [<i>addrglob</i> . . .]</pre> <p>Only allow users to login as <i>username</i> from host(s) that match <i>addrglob</i>.</p> <pre>deny <i>username addrglob</i> [<i>addrglob</i> . . .]</pre> <p>Do not allow users to login as <i>username</i> from host(s) that match <i>addrglob</i>.</p> <p>A <i>username</i> of <code>*</code> matches all users. A <i>username</i> of <code>anonymous</code> or <code>ftp</code> specifies the anonymous user.</p> <p><i>addrglob</i> is a regular expression that is matched against hostnames or IP addresses. <i>addrglob</i> may also be in the form <code>address:netmask</code> or <code>address/CIDR</code>, or be the name of a file that starts with a slash (<code>/</code>) and contains additional address globs. An exclamation mark (<code>!</code>) placed before the <i>addrglob</i> negates the test.</p> <p>The first <code>allow</code> or <code>deny</code> entry in the <code>ftphosts</code> file that matches a <i>username</i> and host is used. If no entry exists for a <i>username</i>, then access is allowed. Otherwise, a matching <code>allow</code> entry is required to permit access.</p>				
EXAMPLES	<p>You can use the following <code>ftphosts</code> file to allow anonymous access from any host except those on the class A network 10, with the exception of 10.0.0.* IP addresses, which are allowed access:</p> <pre>allow ftp 10.0.0.* deny ftp 10.*.*.* allow ftp *</pre> <p>10.0.0.* can be written as 10.0.0.0:255.255.255.0 or 10.0.0.0/24.</p>

NAME	ftpservers – FTP Server virtual hosting configuration file										
SYNOPSIS	<code>/etc/ftpd/ftpservers</code>										
DESCRIPTION	<p>The <code>ftpservers</code> file is used to configure complete virtual hosting. In contrast to limited virtual hosting, complete virtual hosting allows separate configuration files to be specified for each virtual host.</p> <p>The set of configuration files for each virtual host are placed in their own directory. The <code>ftpservers</code> file associates the address of each virtual host with the directory its configuration files are stored in. The virtual host configuration files must be named:</p> <table border="0"> <tr> <td><code>ftpaccess</code></td> <td>Virtual host's access file</td> </tr> <tr> <td><code>ftpusers</code></td> <td>Restricts the accounts that can use the virtual host</td> </tr> <tr> <td><code>ftpgroups</code></td> <td>Virtual hosts enhanced group access file</td> </tr> <tr> <td><code>ftphosts</code></td> <td>Allow or deny usernames access to the virtual host</td> </tr> <tr> <td><code>ftpconversions</code></td> <td>Customize conversions available from the virtual host</td> </tr> </table> <p>You do not need to put every file in each virtual host directory. If you want a virtual host to use the master copy of a file, then do not include it in the virtual host directory. If the file is not included, the master copy from the <code>/etc/ftpd</code> directory will be used.</p> <p>The file names must match exactly. If you misspell any of them or name them differently, the server will not find them, and the server will use the master copy instead.</p> <p>The <code>ftppaddhost</code> utility is an administrative tool to configure virtual hosts. See <code>ftppaddhost(1M)</code>.</p>	<code>ftpaccess</code>	Virtual host's access file	<code>ftpusers</code>	Restricts the accounts that can use the virtual host	<code>ftpgroups</code>	Virtual hosts enhanced group access file	<code>ftphosts</code>	Allow or deny usernames access to the virtual host	<code>ftpconversions</code>	Customize conversions available from the virtual host
<code>ftpaccess</code>	Virtual host's access file										
<code>ftpusers</code>	Restricts the accounts that can use the virtual host										
<code>ftpgroups</code>	Virtual hosts enhanced group access file										
<code>ftphosts</code>	Allow or deny usernames access to the virtual host										
<code>ftpconversions</code>	Customize conversions available from the virtual host										
File Format	<p>There are two fields to each entry in the <code>ftpservers</code> file:</p> <pre>address directory-containing-configuration-files</pre> <p>For example:</p> <pre>10.196.145.10 /etc/ftpd/virtual-ftp/10.196.145.10 10.196.145.200 /etc/ftpd/virtual-ftp/10.196.145.200 some.domain INTERNAL</pre> <p>When an FTP client connects to the FTP Server, <code>in.ftpd(1M)</code> tries to match the IP address to which the FTP client connected with one found in the <code>ftpservers</code> file.</p> <p>The address can be an IPv4 or IPv6 address, or a hostname.</p> <p>If a match is found, The FTP server uses any configuration files found in the associated directory.</p>										

ftpservers(4)

If a match is not found, or an invalid directory path is encountered, the default paths to the configuration files are used. The use of `INTERNAL` in the example above fails the check for a specific directory, and the master configuration files will be used.

Either the actual IP address or a specific hostname can be used to specify the virtual host. It is better to specify the actual IP of the virtual host, as it reduces the need for a domain lookup and eliminates DNS security related naming issues, for example:

```
10.196.145.20    /etc/ftpd/config/faqs.org/  
ftp.some.domain /etc/ftpd/config/faqs.org/
```

Lines that begin with a # sign are treated as comment lines and are ignored.

NAME	ftputers – file listing users to be disallowed ftp login privileges
SYNOPSIS	<code>/etc/ftpd/ftputers</code>
DESCRIPTION	<p>The <code>ftputers</code> file lists users for whom ftp login privileges are disallowed. Each <code>ftputer</code> entry is a single line of the form:</p> <pre>name</pre> <p>where <code>name</code> is the user's login name.</p> <p>The FTP Server, in <code>ftpd(1M)</code>, reads the <code>ftputers</code> file. If the login name of the user matches one of the entries listed, it rejects the login attempt.</p> <p>The <code>ftputers</code> file has the following default configuration entries:</p> <pre>root daemon bin sys adm lp uucp nuucp smmsp listen nobody noaccess nobody4</pre> <p>These entries match the default instantiated entries from <code>passwd(4)</code>. The list of default entries typically contains the superuser <code>root</code> and other administrative and system application identities.</p> <p>The <code>root</code> entry is included in the <code>ftputers</code> file as a security measure since the default policy is to disallow remote logins for this identity. This policy is also set in the the default value of the <code>CONSOLE</code> entry in the <code>/etc/default/login</code> file. See <code>login(1)</code>. If you allow <code>root</code> login privileges by deleting the <code>root</code> entry in <code>ftputers</code>, you should also modify the security policy in <code>/etc/default/login</code> to reflect the site security policy for remote login access by <code>root</code>.</p> <p>Other default entries are administrative identities that are typically assumed by system applications but never used for local or remote login, for example <code>sys</code> and <code>nobody</code>. Since these entries do not have a valid password field instantiated in <code>shadow(4)</code>, no login can be performed.</p> <p>If a site adds similar administrative or system application identities in <code>passwd(4)</code> and <code>shadow(4)</code>, for example, <code>major_domo</code>, the site should consider including them in the <code>ftputers</code> file for a consistent security policy.</p> <p>Lines that begin with <code>#</code> are treated as comment lines and are ignored.</p>

ftusers(4)

FILES /etc/ftpd/ftusers A file that lists users for whom ftp login privileges are disallowed.

/etc/ftusers See /etc/ftpd/ftusers. This file is deprecated, although its use is still supported.

NAME	fx_dptbl – fixed priority dispatcher parameter table
SYNOPSIS	fx_dptbl
DESCRIPTION	<p>The process scheduler (or dispatcher) is the portion of the kernel that controls allocation of the CPU to processes. The scheduler supports the notion of scheduling classes, where each class defines a scheduling policy used to schedule processes within that class. Associated with each scheduling class is a set of priority queues on which ready-to-run processes are linked. These priority queues are mapped by the system configuration into a set of global scheduling priorities, which are available to processes within the class. (The dispatcher always selects for execution the process with the highest global scheduling priority in the system.) The priority queues associated with a given class are viewed by that class as a contiguous set of priority levels numbered from 0 (lowest priority) to <i>n</i> (highest priority—a configuration-dependent value). The set of global scheduling priorities that the queues for a given class are mapped into might not start at zero and might not be contiguous, depending on the configuration.</p> <p>Processes in the fixed priority class are scheduled according to the parameters in a fixed-priority dispatcher parameter table (<code>fx_dptbl</code>). The <code>fx_dptbl</code> table consists of an array (<code>config_fx_dptbl []</code>) of parameter structures (<code>struct fxdpent_t</code>), one for each of the <i>n</i> priority levels used by fixed priority processes in user mode. The structures are accessed via a pointer, (<code>fx_dptbl</code>), to the array. The properties of a given priority level <i>i</i> are specified by the <i>i</i>th parameter structure in this array (<code>fx_dptbl [i]</code>).</p> <p>A parameter structure consists of the following members. These are also described in the <code>/usr/include/sys/fx.h</code> header.</p> <p><code>fx_globpri</code> The global scheduling priority associated with this priority level. The mapping between fixed-priority priority levels and global scheduling priorities is determined at boot time by the system configuration. <code>fx_globpri</code> can not be changed with <code>dispadmin(1M)</code>.</p> <p><code>fx_quantum</code> The length of the time quantum allocated to processes at this level in ticks (Hz). The time quantum value is only a default or starting value for processes at a particular level, as the time quantum of a fixed priority process can be changed by the user with the <code>priocntl(1)</code> command or the <code>priocntl(2)</code> system call.</p> <p>An administrator can affect the behavior of the fixed priority portion of the scheduler by reconfiguring the <code>fx_dptbl</code>. There are two methods available for doing this: reconfigure with a loadable module at boot-time or by using <code>dispadmin(1M)</code> at run-time.</p> <p><code>fx_dptbl</code> Loadable Module</p> <p>The <code>fx_dptbl</code> can be reconfigured with a loadable module that contains a new fixed priority dispatch table. The module containing the dispatch table is separate from the FX loadable module, which contains the rest of the fixed priority software. This is the</p>

fx_dptbl(4)

dispadmin
Configuration
File

only method that can be used to change the number of fixed priority priority levels or the set of global scheduling priorities used by the fixed priority class. The relevant procedure and source code is described in "Replacing the `fx_dptbl` Loadable Module," below.

The `fx_quantum` values in the `fx_dptbl` can be examined and modified on a running system using the `dispadmin(1M)` command. Invoking `dispadmin` for the fixed-priority class allows the administrator to retrieve the current `fx_dptbl` configuration from the kernel's in-core table or overwrite the in-core table with values from a configuration file. The configuration file used for input to `dispadmin` must conform to the specific format described as follows:

- Blank lines are ignored and any part of a line to the right of a `#` symbol is treated as a comment.
- The first non-blank, non-comment line must indicate the resolution to be used for interpreting the time quantum values. The resolution is specified as:

```
RES=res
```

where *res* is a positive integer between 1 and 1,000,000,000 inclusive and the resolution used is the reciprocal of *res* in seconds (for example, `RES=1000` specifies millisecond resolution). Although you can specify very fine (nanosecond) resolution, the time quantum lengths are rounded up to the next integral multiple of the system clock's resolution.

- The remaining lines in the file are used to specify the `fx_quantum` values for each of the fixed-priority priority levels. The first line specifies the quantum for fixed-priority level 0, the second line specifies the quantum for fixed-priority level 1, and so forth. There must be exactly one line for each configured fixed priority priority level. Each `fx_quantum` entry must be a positive integer specifying the desired time quantum in the resolution given by *res*.

See EXAMPLES, below, for an example of an excerpt of a `dispadmin` configuration file.

Replacing the
fx_dptbl
Loadable
Module

To change the size of the fixed priority dispatch table, you must build the loadable module that contains the dispatch table information. Save the existing module before using the following procedure.

1. Place the dispatch table code shown below in a file called `fx_dptbl.c`. See EXAMPLES, below, for an example of this file.

2. Compile the code using the given compilation and link lines supplied:

```
cc -c -o -D_KERNEL fx_dptbl.c  
ld -r -o FX_DPTBL fx_dptbl.o
```

3. Copy the current dispatch table in `/usr/kernel/sched` to `FX_DPTBL.bak`.
4. Replace the current `FX_DPTBL` in `/usr/kernel/sched`.
5. Make changes in the `/etc/system` file to reflect the changes to the sizes of the tables. See `system(4)`. The variables affected is `fx_maxupri`. The syntax for setting this is as follows:

```
set FX:fx_maxupri= (value for max fixed-priority user priority)
```

6. Reboot the system to use the new dispatch table.

Note – Exercise great care in using the preceding method to replace the dispatch table. A mistake can result in panics, thus making the system unusable.

EXAMPLES

EXAMPLE 1 Configuration File Excerpt

The following excerpt from a `dispadmin` configuration file illustrates the correct format. Note that, for each line specifying a set of parameters, there is a comment indicating the corresponding priority level. These level numbers indicate priority within the fixed priority class; the mapping between these fixed-priority priorities and the corresponding global scheduling priorities is determined by the configuration specified in the `FX_DPTBL` loadable module. The level numbers are strictly for the convenience of the administrator reading the file and, as with any comment, they are ignored by `dispadmin`. The `dispadmin` command assumes that the lines in the file are ordered by consecutive, increasing priority level (from 0 to the maximum configured fixed-priority priority). For the sake of someone reading the file, the level numbers in the comments should agree with this ordering. If for some reason they do not, `dispadmin` is unaffected.

```
# Fixed Priority Dispatcher Configuration File RES=1000
```

```
RES=1000
#   TIME QUANTUM           PRIORITY
# (fx_quantum)           LEVEL
200                          #   0
200                          #   1
200                          #   2
200                          #   3
200                          #   4
200                          #   5
200                          #   6
200                          #   7
.                             .   .
.                             .   .
.                             .   .
20                           #  58
20                           #  59
```

EXAMPLE 2 `fx_dptbl.c` File Used for Building the New `fx_dptbl`

The following is an example of a `fx_dptbl.c` file used for building the new `fx_dptbl`.

```
/* BEGIN fx_dptbl.c */

#include <sys/proc.h>
#include <sys/priocntl.h>
#include <sys/class.h>

System Administration Guide, Volume 1, System Interface Guide

NAME	geniconvtbl – geniconvtbl input file format																								
DESCRIPTION	<p>An input file to <code>geniconvtbl</code> is an ASCII text file that contains an <code>iconv</code> code conversion definition from one codeset to another codeset.</p> <p>The <code>geniconvtbl</code> utility accepts the code conversion definition file(s) and writes code conversion binary table file(s) that can be used in <code>iconv(1)</code> and <code>iconv(3C)</code> to support user-defined code conversions. See <code>iconv(1)</code> and <code>iconv(3C)</code> for more detail on the <code>iconv</code> code conversion and <code>geniconvtbl(1)</code> for more detail on the utility.</p>																								
The Lexical Conventions	<p>The following lexical conventions are used in the <code>iconv</code> code conversion definition:</p> <p>CONVERSION_NAME A string of characters representing the name of the <code>iconv</code> code conversion. The <code>iconv</code> code conversion name should start with one or more printable ASCII characters followed by a percentage character <code>'%'</code> followed by another one or more of printable ASCII characters. Examples: ISO8859-1%ASCII, 646%eucJP, CP_939%ASCII.</p> <p>NAME A string of characters starts with any one of the ASCII alphabet characters or the underscore character, <code>'_'</code>, followed by one or more ASCII alphanumeric characters and underscore character, <code>'_'</code>. Examples: <code>_a1</code>, <code>ABC_codeset</code>, <code>K1</code>.</p> <p>HEXADECIMAL A hexadecimal number. The hexadecimal representation consists of an escape character, <code>'0'</code> followed by the constant <code>'x'</code> or <code>'X'</code> and one or more hexadecimal digits. Examples: <code>0x0</code>, <code>0x1</code>, <code>0x1a</code>, <code>0X1A</code>, <code>0x1B3</code>.</p> <p>DECIMAL A decimal number, represented by one or more decimal digits. Examples: <code>0</code>, <code>123</code>, <code>2165</code>.</p> <p>Each comment starts with <code>'//'</code> ends at the end of the line.</p> <p>The following keywords are reserved:</p> <table border="0" style="width: 100%;"> <tr> <td>automatic</td> <td>between</td> <td>binary</td> </tr> <tr> <td>break</td> <td>condition</td> <td>default</td> </tr> <tr> <td>dense</td> <td>direction</td> <td>discard</td> </tr> <tr> <td>else</td> <td>error</td> <td>escapeseq</td> </tr> <tr> <td>false</td> <td>if</td> <td>index</td> </tr> <tr> <td>init</td> <td>input</td> <td>inputsize</td> </tr> <tr> <td>map</td> <td>maptype</td> <td>no_change_copy</td> </tr> <tr> <td>operation</td> <td>output</td> <td>output_byte_length</td> </tr> </table>	automatic	between	binary	break	condition	default	dense	direction	discard	else	error	escapeseq	false	if	index	init	input	inputsize	map	maptype	no_change_copy	operation	output	output_byte_length
automatic	between	binary																							
break	condition	default																							
dense	direction	discard																							
else	error	escapeseq																							
false	if	index																							
init	input	inputsize																							
map	maptype	no_change_copy																							
operation	output	output_byte_length																							

geniconvtbl(4)

```
outputsize          printchr          printhd
printint            reset            return
true
```

Additionally, the following symbols are also reserved as tokens:

```
{ } [ ] ( ) ; , ...
```

The precedence and associativity

The following table shows the precedence and associativity of the operators from lower precedence at the top to higher precedence at the bottom of the table allowed in the iconv code conversion definition:

Operator (Symbol)	Associativity
Assignment (=)	Right
Logical OR ()	Left
Logical AND (&&)	Left
Bitwise OR ()	Left
Exclusive OR (^)	Left
Bitwise AND (&)	Left
Equal-to (= =), Inequality (!=)	Left
Less-than (<), Less-than-or-equal-to (<=), Greater-than (>), Greater-than-or-equal-to (>=)	Left
Left-shift (<<), Right-shift (>>)	Left
Addition (+), Subtraction (-)	Left
Multiplication (*), Division (/), Remainder (%)	Left
Logical negation (!),	Right

The Syntax

```
Bitwise complement (~),
Unary minus (-)
-----
```

Each iconv code conversion definition starts with `CONVERSION_NAME` followed by one or more semi-colon separated code conversion definition elements:

```
// a US-ASCII to ISO8859-1 iconv code conversion example:
US-ASCII%ISO8859-1 {

    // one or more code conversion definition elements here.

    :
    :
}
```

Each code conversion definition element can be any one of the following elements:

```
direction
condition
operation
map
```

To have a meaningful code conversion, there should be at least one direction, operation, or map element in the iconv code conversion definition.

The direction element contains one or more semi-colon separated condition-action pairs that direct the code conversion:

```
direction For_US-ASCII_2_ISO8859-1 {

    // one or more condition-action pairs here.
    :
    :
}
```

Each condition-action pair contains a conditional code conversion that consists of a condition element and an action element.

```
condition action
```

If the pre-defined condition is met, the corresponding action is executed. If there is no pre-defined condition met, `iconv(3C)` will return `-1` with `errno` set to `EILSEQ`. The condition can be a condition element, a name to a pre-defined condition element, or a condition literal value, `true`. The `'true'` condition literal value always yields success and thus the corresponding action is always executed. The action also can be an action element or a name to a pre-defined action element.

The condition element specifies one or more condition expression elements. Since each condition element can have a name and also can exist stand-alone, a pre-defined condition element can be referenced by the name at any action pairs later. To be used in that way, the corresponding condition element should be defined beforehand:

```
condition For_US-ASCII_2_ISO8859-1 {
    // one or more condition expression elements here.
    :
    :
}
```

The name of the condition element in the above example is `For_US-ASCII_2_ISO8859-1`. Each condition element can have one or more condition expression elements. If there are more than one condition expression elements, the condition expression elements are checked from top to bottom to see if any one of the condition expression elements will yield a true. Any one of the following can be a condition expression element:

between
escapeseq
expression

The between condition expression element defines one or more comma-separated ranges:

```
between 0x0...0x1f, 0x7f...0x9f ;
between 0xa1a1...0xfe fe ;
```

In the first expression in the example above, the covered ranges are 0x0 to 0x1f and 0x7f to 0x9f inclusively. In the second expression, the covered range is the range whose first byte is 0xa1 to 0xfe and whose second byte is between 0xa1 to 0xfe. This means that the range is defined by each byte. In this case, the sequence 0xa280 does not meet the range.

The escapeseq condition expression element defines an equal-to condition for one or more comma-separated escape sequence designators:

```
// ESC $ ) C sequence:
escapeseq 0x1b242943;

// ESC $ ) C sequence or ShiftOut (SO) control character code, 0x0e:
escapeseq 0x1b242943, 0x0e;
```

The expression can be any one of the following and can be surrounded by a pair of parentheses, '(' and ')':

```
// HEXADECIMAL:
0xa1a1
```

```
// DECIMAL
12

// A boolean value, true:
true

// A boolean value, false:
false

// Addition expression:
1 + 2

// Subtraction expression:
10 - 3

// Multiplication expression:
0x20 * 10

// Division expression:
20 / 10

// Remainder expression:
17 % 3

// Left-shift expression:
1 << 4

// Right-shift expression:
0xa1 >> 2

// Bitwise OR expression:
0x2121 | 0x8080

// Exclusive OR expression:
0xa1a1 ^ 0x8080

// Bitwise AND expression:
0xa1 & 0x80

// Equal-to expression:
0x10 == 16

// Inequality expression:
0x10 != 10

// Less-than expression:
0x20 < 25

// Less-than-or-equal-to expression:
10 <= 0x10

// Bigger-than expression:
0x10 > 12

// Bigger-than-or-equal-to expression:
0x10 >= 0xa
```

geniconvtbl(4)

```
// Logical OR expression:
0x10 || false

// Logical AND expression:
0x10 && false

// Logical negation expression:
! false

// Bitwise complement expression:
~0

// Unary minus expression:
-123
```

There is a single type available in this expression: integer. The boolean values are two special cases of integer values. The 'true' boolean value's integer value is 1 and the 'false' boolean value's integer value is 0. Also, any integer value other than 0 is a true boolean value. Consequently, the integer value 0 is the false boolean value. Any boolean expression yields integer value 1 for true and integer value 0 for false as the result.

Any literal value shown at the above expression examples as operands, that is, DECIMAL, HEXADECIMAL, and boolean values, can be replaced with another expression. There are a few other special operands that you can use as well in the expressions: 'input', 'inputsize', 'outputsize', and variables. input is a keyword pointing to the current input buffer. inputsize is a keyword pointing to the current input buffer size in bytes. outputsize is a keyword pointing to the current output buffer size in bytes. The NAME lexical convention is used to name a variable. The initial value of a variable is 0. The following expressions are allowed with the special operands:

```
// Pointer to the third byte value of the current input buffer:
input[2]

// Equal-to expression with the 'input':
input == 0x8020

// Alternative way to write the above expression:
0x8020 == input

// The size of the current input buffer size:
inputsize

// The size of the current output buffer size:
outputsize

// A variable:
saved_second_byte

// Assignment expression with the variable:
saved_second_byte = input[1]
```

The input keyword without index value can be used only with the equal-to operator, '=='. When used in that way, the current input buffer is consecutively compared with another operand byte by byte. An expression can be another operand. If the input keyword is used with an index value n , it is a pointer to the $(n+1)$ th byte from the beginning of the current input buffer. An expression can be the index. Only a variable can be placed on the left hand side of an assignment expression.

The action element specifies an action for a condition and can be any one of the following elements:

direction
operation
map

The operation element specifies one or more operation expression elements:

```
operation For_US-ASCII_2_ISO8859-1 {
    // one or more operation expression element definitions here.
    :
    :
}
```

If the name of the operation element, in the case of the above example, For_US-ASCII_2_ISO8859-1, is either `init` or `reset`, it defines the initial operation and the reset operation of the iconv code conversion:

```
// The initial operation element:
operation init {
    // one or more operation expression element definitions here.
    :
    :
}

// The reset operation element:
operation reset {
    // one or more operation expression element definitions here.
    :
    :
}
```

The initial operation element defines the operations that need to be performed in the beginning of the iconv code conversion. The reset operation element defines the operations that need to be performed when a user of the iconv(3) function requests a state reset of the iconv code conversion. For more detail on the state reset, refer to iconv(3C).

The operation expression can be any one of the following three different expressions and each operation expression should be separated by an ending semicolon:

if-else operation expression
 output operation expression
 control operation expression

The if-else operation expression makes a selection depend on the boolean expression result. If the boolean expression result is true, the true task that follows the 'if' is executed. If the boolean expression yields false and if a false task is supplied, the false task that follows the 'else' is executed. There are three different kinds of if-else operation expressions:

```
// The if-else operation expression with only true task:
if (expression) {

    // one or more operation expression element definitions here.
    :
    :

}

// The if-else operation expression with both true and false
// tasks:
if (expression) {

    // one or more operation expression element definitions here.
    :
    :

} else {

    // one or more operation expression element definitions here.
    :
    :

}

// The if-else operation expression with true task and
// another if-else operation expression as the false task:
if (expression) {

    // one or more operation expression element definitions here.
    :
    :

} else if (expression) {

    // one or more operation expression element definitions here.
    :
    :

} else {
```

```

    // one or more operation expression element definitions here.
    :
    :
}

```

The last if-else operation expression can have another if-else operation expression as the false task. The other if-else operation expression can be any one of above three if-else operation expressions.

The output operation expression saves the right hand side expression result to the output buffer:

```

// Save 0x8080 at the output buffer:
output = 0x8080;

```

If the size of the output buffer left is smaller than the necessary output buffer size resulting from the right hand side expression, the iconv code conversion will stop with E2BIG errno and (size_t)-1 return value to indicate that the code conversion needs more output buffer to complete. Any expression can be used for the right hand side expression. The output buffer pointer will automatically move forward appropriately once the operation is executed.

The control operation expression can be any one of the following expressions:

```

// Return (size_t)-1 as the return value with an EINVAL errno:
error;

// Return (size_t)-1 as the return value with an EBADF errno:
error 9;

// Discard input buffer byte operation. This discards a byte from
// the current input buffer and move the input buffer pointer to
// the 2'nd byte of the input buffer:
discard;

// Discard input buffer byte operation. This discards
// 10 bytes from the current input buffer and move the input
// buffer pointer to the 11'th byte of the input buffer:
discard 10;

// Return operation. This stops the execution of the current
// operation:
return;

// Operation execution operation. This executes the init
// operation defined and sets all variables to zero:
operation init;

// Operation execution operation. This executes the reset
// operation defined and sets all variables to zero:
operation reset;

```

geniconvtbl(4)

```
// Operation execution operation. This executes an operation
// defined and named 'ISO8859_1_to_ISO8859_2':
operation ISO8859_1_to_ISO8859_2;

// Direction operation. This executes a direction defined and
// named 'ISO8859_1_to_KOI8_R':
direction ISO8859_1_to_KOI8_R;

// Map execution operation. This executes a mapping defined
// and named 'Map_ISO8859_1_to_US_ASCII':
map Map_ISO8859_1_to_US_ASCII;

// Map execution operation. This executes a mapping defined
// and named 'Map_ISO8859_1_to_US_ASCII' after discarding
// 10 input buffer bytes:
map Map_ISO8859_1_to_US_ASCII 10;
```

In case of init and reset operations, if there is no pre-defined init and/or reset operations in the iconv code conversions, only system-defined internal init and reset operations will be executed. The execution of the system-defined internal init and reset operations will clear the system-maintained internal state.

There are three special operators that can be used in the operation:

```
printchr expression;
printhd expression;
printint expression;
```

The above three operators will print out the given expression as a character, a hexadecimal number, and a decimal number, respectively, at the standard error stream. These three operators are for debugging purposes only and should be removed from the final version of the iconv code conversion definition file.

In addition to the above operations, any valid expression separated by a semi-colon can be an operation, including an empty operation, denoted by a semi-colon alone as an operation.

The map element specifies a direct code conversion mapping by using one or more map pairs. When used, usually many map pairs are used to represent an iconv code conversion definition:

```
map For_US-ASCII_2_ISO8859-1 {
    // one or more map pairs here
    :
    :
}
```

Each map element also can have one or two comma-separated map attribute elements like the following examples:

```

// Map with densely encoded mapping table map type:
map maptype = dense {

    // one or more map pairs here
    :
    :
}

// Map with hash mapping table map type with hash factor 10.
// Only hash mapping table map type can have hash factor. If
// the hash factor is specified with other map types, it will be
// ignored.
map maptype = hash : 10 {

    // one or more map pairs here.
    :
    :
}

// Map with binary search tree based mapping table map type:
map maptype = binary {

    // one more more map pairs here.
    :
    :
}

// Map with index table based mapping table map type:
map maptype = index {

    // one or more map pairs here.
    :
    :
}

// Map with automatic mapping table map type. If defined,
// system will assign the best possible map type.
map maptype = automatic {

    // one or more map pairs here.
    :
    :
}

// Map with output_byte_length limit set to 2.
map output_byte_length = 2 {

    // one or more map pairs here.
    :
    :
}
}

```

geniconvtbl(4)

```
// Map with densely encoded mapping table map type and
// output_bute_length limit set to 2:
map maptype = dense, output_byte_length = 2 {

    // one or more map pairs here.
    :
    :
}
}
```

If no maptype is defined, automatic is assumed. If no output_byte_length is defined, the system figures out the maximum possible output byte length for the mapping by scanning all the possible output values in the mappings. If the actual output byte length scanned is bigger than the defined output_byte_length, the geniconvtbl utility issues an error and stops generating the code conversion binary table(s).

The following are allowed map pairs:

```
// Single mapping. This maps an input character denoted by
// the code value 0x20 to an output character value 0x21:
0x20      0x21

// Multiple mapping. This maps 128 input characters to 128
// output characters. In this mapping, 0x0 maps to 0x10, 0x1 maps
// to 0x11, 0x2 maps to 0x12, ..., and, 0x7f maps to 0x8f:
0x0...0x7f 0x10

// Default mapping. If specified, every undefined input character
// in this mapping will be converted to a specified character
// (in the following case, a character with code value of 0x3f):
default    0x3f;

// Default mapping. If specified, every undefined input character
// in this mapping will not be converted but directly copied to
// the output buffer:
default    no_change_copy;

// Error mapping. If specified, during the code conversion,
// if input buffer contains the byte value, in this case, 0x80,
// the iconv(3) will stop and return (size_t)-1 as the return
// value with EILSEQ set to the errno:
0x80      error;
```

If no default mapping is specified, every undefined input character in the mapping will be treated as an error mapping, and thus the iconv(3C) will stop the code conversion and return (size_t)-1 as the return value with EILSEQ set to the errno.

The syntax of the iconv code conversion definition in extended BNF is illustrated below:

```
iconv_conversion_definition
    : CONVERSION_NAME '{' definition_element_list '}'

maximum length of a variable is 255. The maximum nest level is 16.

NAME	group – group file
DESCRIPTION	<p>The <code>group</code> file is a local source of group information. The <code>group</code> file can be used in conjunction with other group sources, including the NIS maps <code>group.byname</code> and <code>group.bygid</code> and the NIS+ table <code>group</code>. Programs use the <code>getgrnam(3C)</code> routines to access this information.</p> <p>The <code>group</code> file contains a one-line entry for each group recognized by the system, of the form:</p> <pre>groupname:password:gid:user-list</pre> <p>where</p> <p><i>groupname</i> The name of the group.</p> <p><i>gid</i> The group's unique numerical ID (GID) within the system.</p> <p><i>user-list</i> A comma-separated list of users allowed in the group.</p> <p>The maximum value of the <i>gid</i> field is 2147483647. To maximize interoperability and compatibility, administrators are recommended to assign groups using the range of GIDs below 60000 where possible.</p> <p>If the password field is empty, no password is demanded. During user identification and authentication, the supplementary group access list is initialized sequentially from information in this file. If a user is in more groups than the system is configured for, {NGROUPS_MAX}, a warning will be given and subsequent group specifications will be ignored.</p> <p>Malformed entries cause routines that read this file to halt, in which case group assignments specified further along are never made. To prevent this from happening, use <code>grpck(1B)</code> to check the <code>/etc/group</code> database from time to time.</p> <p>Previous releases used a group entry beginning with a '+' (plus sign) or '-' (minus sign) to selectively incorporate entries from NIS maps for group. If still required, this is supported by specifying <code>group:compat</code> in <code>nsswitch.conf(4)</code>. The "compat" source may not be supported in future releases. The preferred sources are, "files" followed by "nisplus". This has the effect of incorporating the entire contents of the NIS+ group table after the group file.</p>
EXAMPLES	<p>EXAMPLE 1 Sample of a group file.</p> <p>Here is a sample group file:</p> <pre>root::0:root stooges:q.mJzTnu8icF.:10:larry,moe,curly</pre> <p>and the sample group entry from <code>nsswitch.conf</code>:</p> <pre>group: files nisplus</pre>

group(4)

EXAMPLE 1 Sample of a group file. (Continued)

With these entries, the group `stooges` will have members `larry`, `moe`, and `curly`, and all groups listed in the NIS+ group table are effectively incorporated after the entry for `stooges`.

If the group file was:

```
root::0:root
stooges:q.mJzTnu8icF.:10:larry,moe,curly
+:
```

and the group entry from `nsswitch.conf`:

```
group: compat
```

all the groups listed in the NIS `group.bygid` and `group.byname` maps would be effectively incorporated after the entry for `stooges`.

System Administration Guide: Basic Administration

NAME holidays – prime/nonprime table for the accounting system

SYNOPSIS /etc/acct/holidays

DESCRIPTION The /etc/acct/holidays file describes which hours are considered prime time and which days are holidays. Holidays and weekends are considered non-prime time hours. /etc/acct/holidays is used by the accounting system.

All lines beginning with an "*" are comments.

The /etc/acct/holidays file consists of two sections. The first non-comment line defines the current year and the start time of prime and non-prime time hours, in the form:

```
current_year    prime_start    non_prime_start
```

The remaining non-comment lines define the holidays in the form:

```
month/day    company_holiday
```

Of these two fields, only the *month/day* is actually used by the accounting system programs.

The /etc/acct/holidays file must be updated each year.

EXAMPLES **EXAMPLE 1** Example of the /etc/acct/holidays file.

The following is an example of the /etc/acct/holidays file:

```
* Prime/Nonprime Table for the accounting system
*
* Curr      Prime      Non-Prime
* Year      Start      Start
*
  1991      0830      1800
*
* only the first column (month/day) is significant.
*
* month/day    Company Holiday
*
  1/1          New Years Day
  5/30         Memorial Day
  7/4          Indep. Day
  9/5          Labor Day
  11/24        Thanksgiving Day
  11/25        day after Thanksgiving
  12/25        Christmas
  12/26        day after Christmas
```

SEE ALSO acct(1M)

hosts(4)

NAME	hosts – host name database
SYNOPSIS	<pre>/etc/inet/hosts /etc/hosts</pre>
DESCRIPTION	<p>The <code>hosts</code> file is a local database that associates the names of hosts with their Internet Protocol (IP) addresses. The <code>hosts</code> file can be used in conjunction with, or instead of, other hosts databases, including the Domain Name System (DNS), the NIS <code>hosts</code> map and the NIS+ <code>hosts</code> table. Programs use library interfaces to access information in the <code>hosts</code> file.</p> <p>The <code>hosts</code> file has one entry for each IP address of each host. If a host has more than one IP address, it will have one entry for each, on consecutive lines. The format of each line is:</p> <pre>IP-address official-host-name nicknames . . .</pre> <p>Items are separated by any number of SPACE and/or TAB characters. The first item on a line is the host's IP address. The second entry is the host's official name. Subsequent entries on the same line are alternative names for the same machine, or "nicknames." Nicknames are optional.</p> <p>For a host with more than one IP address, consecutive entries for these addresses may contain the same or differing nicknames. Different nicknames are useful for assigning distinct names to different addresses.</p> <p>A call to <code>gethostbyname(3NSL)</code> returns a <code>hostent</code> structure containing the union of all addresses and nicknames from each line containing a matching official name or nickname.</p> <p>A '#' indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines that search the file.</p> <p>Network addresses are written in the conventional "decimal dot" notation and interpreted using the <code>inet_addr</code> routine from the Internet address manipulation library, <code>inet(3SOCKET)</code>.</p> <p>This interface supports host names as defined in Internet RFC 952 which states:</p> <p>A "name" (Net, Host, Gateway, or Domain name) is a text string up to 24 characters drawn from the alphabet (A-Z), digits (0-9), minus sign (-), and period (.). Note that periods are only allowed when they serve to delimit components of "domain style names". (See RFC 921, "Domain Name System Implementation Schedule," for background). No blank or space characters are permitted as part of a name. No distinction is made between upper and lower case. The first character must be an alpha character. The last character must not be a minus sign or period.</p>

Although the interface accepts host names longer than 24 characters for the host portion (exclusive of the domain component), choosing names for hosts that adhere to the 24 character restriction will insure maximum interoperability on the Internet.

A host which serves as a GATEWAY should have “-GATEWAY” or “-GW” as part of its name. Hosts which do not serve as Internet gateways should not use “-GATEWAY” and “-GW” as part of their names. A host which is a TAC should have “-TAC” as the last part of its host name, if it is a DoD host. Single character names or nicknames are not allowed.

RFC 952 has been modified by RFC 1123 to relax the restriction on the first character being a digit.

EXAMPLES **EXAMPLE 1** Example of a typical line from the `hosts` file.

Here is a typical line from the `hosts` file:

```
192.9.1.20      gaia                # John Smith
```

SEE ALSO `in.named(1M)`, `gethostbyname(3NSL)`, `inet(3SOCKET)`, `nsswitch.conf(4)`, `resolv.conf(4)`

NOTES `/etc/inet/hosts` is the official SVR4 name of the `hosts` file. The symbolic link `/etc/hosts` exists for BSD compatibility.

hosts.equiv(4)

NAME	hosts.equiv, rhosts – trusted remote hosts and users
DESCRIPTION	<p>The <code>/etc/hosts.equiv</code> and <code>.rhosts</code> files provide the “remote authentication” database for <code>rlogin(1)</code>, <code>rsh(1)</code>, <code>rcp(1)</code>, and <code>rcmd(3SOCKET)</code>. The files specify remote hosts and users that are considered “trusted”. Trusted users are allowed to access the local system without supplying a password. The library routine <code>ruserok()</code> (see <code>rcmd(3SOCKET)</code>) performs the authentication procedure for programs by using the <code>/etc/hosts.equiv</code> and <code>.rhosts</code> files. The <code>/etc/hosts.equiv</code> file applies to the entire system, while individual users can maintain their own <code>.rhosts</code> files in their home directories.</p> <p>These files bypass the standard password-based user authentication mechanism. To maintain system security, care must be taken in creating and maintaining these files.</p> <p>The remote authentication procedure determines whether a user from a remote host should be allowed to access the local system with the identity of a local user. This procedure first checks the <code>/etc/hosts.equiv</code> file and then checks the <code>.rhosts</code> file in the home directory of the local user who is requesting access. Entries in these files can be of two forms. Positive entries allow access, while negative entries deny access. The authentication succeeds when a matching positive entry is found. The procedure fails when the first matching negative entry is found, or if no matching entries are found in either file. The order of entries is important. If the files contain both positive and negative entries, the entry that appears first will prevail. The <code>rsh(1)</code> and <code>rcp(1)</code> programs fail if the remote authentication procedure fails. The <code>rlogin</code> program falls back to the standard password-based login procedure if the remote authentication fails.</p> <p>Both files are formatted as a list of one-line entries. Each entry has the form:</p> <pre>hostname [username]</pre> <p>Hostnames must be the official name of the host, not one of its nicknames.</p> <p>Negative entries are differentiated from positive entries by a ‘-’ character preceding either the <i>hostname</i> or <i>username</i> field.</p> <p>Positive Entries If the form:</p> <pre>hostname</pre> <p>is used, then users from the named host are trusted. That is, they may access the system with the same user name as they have on the remote system. This form may be used in both the <code>/etc/hosts.equiv</code> and <code>.rhosts</code> files.</p> <p>If the line is in the form:</p> <pre>hostname username</pre> <p>then the named user from the named host can access the system. This form may be used in individual <code>.rhosts</code> files to allow remote users to access the system <i>as a</i></p>

hosts.equiv(4)

different local user. If this form is used in the `/etc/hosts.equiv` file, the named remote user will be allowed to access the system as *any* local user.

`netgroup(4)` can be used in either the *hostname* or *username* fields to match a number of hosts or users in one entry. The form:

`+@netgroup`

allows access from all hosts in the named `netgroup`. When used in the *username* field, `netgroups` allow a group of remote users to access the system as a particular local user. The form:

`hostname +@netgroup`

allows all of the users in the named `netgroup` from the named host to access the system as the local user. The form:

`+@netgroup1 +@netgroup2`

allows the users in `netgroup2` from the hosts in `netgroup1` to access the system as the local user.

The special character '+' can be used in place of either *hostname* or *username* to match any host or user. For example, the entry

`+`

will allow a user from any remote host to access the system with the same username. The entry

`+ username`

will allow the named user from any remote host to access the system. The entry

`hostname +`

will allow any user from the named host to access the system as the local user.

Negative Entries

Negative entries are preceded by a '-' sign. The form:

`-hostname`

will disallow all access from the named host. The form:

`-@netgroup`

means that access is explicitly disallowed from all hosts in the named `netgroup`. The form:

`hostname -username`

disallows access by the named user only from the named host, while the form:

`+ -@netgroup`

hosts.equiv(4)

Search Sequence

will disallow access by all of the users in the named netgroup from all hosts.

To help maintain system security, the `/etc/hosts.equiv` file is not checked when access is being attempted for super-user. If the user attempting access is not the super-user, `/etc/hosts.equiv` is searched for lines of the form described above. Checks are made for lines in this file in the following order:

1. `+`
2. `+%netgroup`
3. `-%netgroup`
4. `-hostname`
5. `hostname`

The user is granted access if a positive match occurs. Negative entries apply only to `/etc/hosts.equiv` and may be overridden by subsequent `.rhosts` entries.

If no positive match occurred, the `.rhosts` file is then searched if the user attempting access maintains such a file. This file is searched whether or not the user attempting access is the super-user. As a security feature, the `.rhosts` file must be owned by the user who is attempting access. Checks are made for lines in `.rhosts` in the following order:

1. `+`
2. `+%netgroup`
3. `-%netgroup`
4. `-hostname`
5. `hostname`

FILES	<code>/etc/hosts.equiv</code>	system trusted hosts and users
	<code>~/.rhosts</code>	user's trusted hosts and users

SEE ALSO `rcp(1)`, `rlogin(1)`, `rsh(1)`, `rcmd(3SOCKET)`, `hosts(4)`, `netgroup(4)`, `passwd(4)`

WARNINGS Positive entries in `/etc/hosts.equiv` that include a *username* field (either an individual named user, a netgroup, or '+' sign) should be used with extreme caution. Because `/etc/hosts.equiv` applies system-wide, these entries allow one, or a group of, remote users to access the system *as any local user*. This can be a security hole. For example, because of the search sequence, an `/etc/hosts.equiv` file consisting of the entries

```
+
-hostxxx
```

will not deny access to "hostxxx".

NAME	ike.config – configuration file for IKE policy
SYNOPSIS	/etc/inet/ike/config
DESCRIPTION	<p>The /etc/inet/ike/config file contains rules for matching inbound IKE requests. It also contains rules for preparing outbound IKE requests.</p> <p>You can test the syntactic correctness of an /etc/inet/ike/config file by using the -c or -f options of in.iked(1M). You must use the -c option to test a config file. You may need to use the -f option if it is not in /etc/inet/ike/config.</p>
Lexical Components	<p>On any line, an unquoted # character introduces a comment; the remainder of that line is ignored. Additionally, on any line, an unquoted // sequence introduces a comment; the remainder of that line is ignored.</p> <p>There are several types of lexical tokens in the ike.config file:</p> <p><i>num</i> A decimal, hex, or octal number representation is as in 'C'.</p> <p><i>IPaddr/prefix/range</i> An IPv4 or IPv6 addresses; with an optional /<i>NNN</i> suffix (where "NNN" is a <i>num</i>) indicates an address (CIDR) prefix (for example, 10.1.2.0/24); with an optional /<i>ADDR</i> suffix (where <i>ADDR</i> is a second IP address) indicates an address / mask pair (for example, 10.1.2.0/255.255.255.0); with an optional -<i>ADDR</i> suffix (where <i>ADDR</i> is a second IP address) indicates an inclusive range of addresses (for example, 10.1.2.0-10.1.2.255). The / or - can be surrounded by an arbitrary amount of whitespace.</p> <p>in.iked(1M) does not support IPv6.</p> <p><i>XXX YYY ZZZ</i> Either the words <i>XXX</i>, <i>YYY</i>, or <i>ZZZ</i>, for example, {yes,no}.</p> <p><i>p1-id-type</i> An IKE phase 1 identity type. IKE phase 1 identity includes:</p> <p>dn, DN dns, DNS fqdn, FQDN gn, GN ip, IP ipv4 ipv4_prefix ipv4_range ipv6 ipv6_prefix ipv6_range mbox, MBOX user_fqdn</p>

ike.config(4)

"string"

A quoted string. Examples include: "Label foo", or "C=US, OU=Sun Microsystems\\, Inc., N=danmcd@eng.sun.com"

A backslash (\) is only an escape character. If the string needs an actual backslash, two must be presented.

cert-sel

A certificate selector, a *string* which specifies the identities of zero or more certificates. The specifiers can conform to X.509 naming conventions. A *cert-sel* can also use various shortcuts to match either subject alternative names, the filename or slot of a certificate in `/etc/inet/ike/publickeys`, or even the ISSUER.

Examples:

```
"SLOT=0"
"EMAIL=postmaster@domain.org"
"webmaster@domain.org" # Some just work w/o TYPE=
"IP=10.0.0.1"
"10.21.11.11"          # Some just work w/o TYPE=
"DNS=www.domain.org"
"mailhost.domain.org" # Some just work w/o TYPE=
"ISSUER=C=US, O=Sun Microsystems\\, Inc., CN=Sun CA"
```

Any *cert-sel* preceded by the character ! indicates a negative match, that is, not matching this specifier. These are the same kind of strings used in `ikecert(1M)`.

ldap-list

A quoted, comma-separated list of LDAP servers and ports, for example, "ldap1.sun.com", "ldap1.sun.com:389", "ldap1.sun.com:389,ldap2.sun.com".

The default port for LDAP is 389.

parameter-list

A list of parameters.

File Body Entries

There are four main types of entries:

- global parameters
- IKE phase 1 transform defaults
- IKE rule defaults
- IKE rules

The global parameter entries are as follows:

<i>cert_root cert-sel</i>	The X.509 distinguished name of a certificate that is a trusted root CA certificate. It must be encoded in a file in the <code>/etc/inet/ike/publickeys</code> directory. It must have a CRL in <code>/etc/inet/ike/crls</code> . Multiple <i>cert_root</i> parameters aggregate.
<i>cert_trust cert-sel</i>	Specifies an X.509 distinguished name of a certificate that is self-signed, or has otherwise been verified as trustworthy for

signing IKE exchanges. It must be encoded in a file in `/etc/inet/ike/publickeys`. Multiple `cert_trust` parameters aggregate.

`ldap_server` *ldap-list* A list of LDAP servers to query for certificates. Can be additive.

The following IKE phase 1 transform parameters can be prefigured using file-level defaults. Values specified within any given transform override these defaults.

The IKE Phase 1 transform defaults are as follows:

`p1_lifetime_secs` *num* The proposed default lifetime, in seconds, of an IKE Phase 1 security association (SA).

`p1_nonce_len` *num* The length, in bytes, of the phase 2 (quick mode) nonce data. N.B.: this cannot be specified on a per-rule basis.

The following IKE rule parameters can be prefigured using file-level defaults. Values specified within any given rule override these defaults, unless a rule cannot.

`p2_nonce_len` *num* The length, in bytes, of the phase 2 (quick mode) nonce data. This cannot be specified on a per-rule basis.

`local_id_type` *p1-id-type* The local identity for IKE requires a type. This identity type is reflected in the IKE exchange. The type can be: IP IP address (for example, 10.1.1.2) DNS DNS name (for example, test.domain.com) MBOX RFC 822 name (for example, root@domain.com) DN X.509 distinguished name (for example, "C=US, O=Sun Microsystems\, Inc., CN=Sun Test cert").

`p1_xform` '{' parameter-list '}' A phase 1 transform specifies a method for protecting an IKE phase 1 exchange. An initiator offers up lists of phase 1 transforms, and a receiver is expected to only accept such an entry if it matches one in a phase 1 rule. There can be several of these, and they are additive. There must be either at least one phase 1 transform in a rule, or a global default phase 1 transform list. A config file without a global default phase 1 transform list *and* a rule without a phase 1 transform list is an invalid file. Elements within the parameter-list; unless specified as optional, each element listed must occur exactly once within a given transform's parameter-list:

`oakley_group` *number*
The Oakley Diffie-Hellman group used for IKE SA key derivation. Acceptable values are currently 1 (768-bit), 2 (1024-bit), or 5 (1536-bit).

ike.config(4)

	<code>encr_alg {3des, 3des-cbc, blowfish, des, des-cbc}</code> An encryption algorithm, as in <code>ipseconf(1m)</code> .
	<code>auth_alg {md5, sha, sha1}</code> An authentication algorithm, as in <code>ipseconf(1m)</code> .
	<code>auth_method {preshared, rsa_sig, rsa_encrypt, dss_sig}</code> The authentication method used for IKE phase 1.
	<code>p1_lifetime_secs num</code> Optional. The lifetime for a phase 1 SA.
<code>p2_lifetime_secs num</code>	If configuring the kernel defaults is not sufficient for different tasks, this parameter can be used on a per-rule basis to set the IPsec SA lifetimes in seconds.
<code>p2_pfs num</code>	The Oakley Diffie-Hellman group used for IPsec SA key derivation. Acceptable values are 0 (do not use Perfect Forward Secrecy for IPsec SAs), 1 (768-bit), 2 (1024-bit), and 5 (1536-bit).
An IKE rule starts with a right-curly-brace (<code>{</code>), ends with a left-curly-brace (<code>}</code>), and has the following parameters in between:	
<code>label string</code>	Required parameter. The administrative interface to <code>in.iked</code> looks up phase 1 policy rules with the label as the search string. The admin interface also converts the label into an index, suitable for an extended ACQUIRE message from PF_KEY - effectively tying IPsec policy to IKE policy in the case of a node initiating traffic. Only one <code>label</code> parameter is allowed per-rule.
<code>local_addr <IPaddr/prefix/range></code>	Required parameter. The local address, address prefix, or address range for this phase 1 rule. Multiple <code>local_addr</code> parameters accumulate within a given rule.
<code>remote_addr <IPaddr/prefix/range></code>	Required parameter. The remote address, address prefix, or address range for this phase 1 rule. Multiple <code>remote_addr</code> parameters accumulate within a given rule.
<code>local_id_type p1-id-type</code>	Which phase 1 identity type I will use. This is needed because a single certificate can contain multiple values for use in IKE phase 1. Within a given rule, all phase 1 transforms must either use preshared or non-preshared authentication (they cannot be mixed). For

local_id <i>cert-sel</i>	rules with preshared authentication, the local_id_type parameter is optional, and defaults to IP. For rules which use non-preshared authentication, the 'local_id_type' parameter is required. Multiple 'local_id_type' parameters within a rule are not allowed.
remote_id <i>cert-sel</i>	Disallowed for preshared authentication method; required parameter for non-preshared authentication method. The local identity string or certificate selector. Multiple local_id parameters accumulate within a given rule.
remote_id <i>cert-sel</i>	Disallowed for preshared authentication method; required parameter for non-preshared authentication method. Selector for which remote phase 1 identities are allowed by this rule. Multiple remote_id parameters accumulate within a given rule. If a single empty string (" ") is given, then this will accept any remote ID for phase1. It is recommended that certificate trust chains or address enforcement be configured strictly to prevent a breakdown in security if this value for remote_id is used.
p2_lifetime_secs <i>num</i>	If configuring the kernel defaults is not sufficient for different tasks, this parameter can be used on a per-rule basis to set the IPsec SA lifetimes in seconds.
p2_pfs <i>num</i>	Use perfect forward secrecy for phase 2 (quick mode). If selected, the oakley group specified will be used for phase 2 PFS. Acceptable values are 0 (do not use Perfect Forward Secrecy for IPsec SAs), 1 (768-bit), 2 (1024-bit), and 5 (1536-bit).
p1_xform { <i>parameter-list</i> }	A phase 1 transform specifies a method for protecting an IKE phase 1 exchange. An initiator offers up lists of phase 1 transforms, and a receiver is expected to only accept such an entry if it matches one in a phase 1 rule. There can be several of these, and they are additive. There must be either at least one phase 1 transform in a rule, or a global default phase 1 transform list. A <code>ike.config</code> file

without a global default phase 1 transform list *and* a rule without a phase 1 transform list is an invalid file. Elements within the parameter-list; unless specified as optional, each element listed must occur exactly once within a given transform's parameter-list:

`oakley_group` *number*

The Oakley Diffie-Hellman group used for IKE SA key derivation. Acceptable values are currently 1 (768-bit), 2 (1024-bit), or 5 (1536-bit).

`encr_alg` {3des, 3des-cbc, blowfish, des, des-cbc}

An encryption algorithm, as in ipsecconf(1m).

`auth_alg` {md5, sha, sha1}

An authentication algorithm, as specified in ipseckey(1M).

`auth_method` {preshared, rsa_sig, rsa_encrypt, dss_sig}

The authentication method used for IKE phase 1.

`p1_lifetime_secs` *num*

Optional. The lifetime for a phase 1 SA.

EXAMPLES **EXAMPLE 1** A Sample `ike.config` File

The following is an example of an `ike.config` file:

```
### BEGINNING OF FILE

### First some global parameters...

### certificate parameters...

# Root certificates. I SHOULD use a full Distinguished Name.
# I must have this certificate in my local filesystem, see ikecert(1m).
cert_root    "C=US, O=Sun Microsystems\\, Inc., CN=Sun CA"

# Explicitly trusted certs that need no signatures, or perhaps self-signed
# ones. Like root certificates, use full DN's for them for now.
cert_trust   "EMAIL=root@domain.org"

# Where do I send LDAP requests?
ldap_server  "ldap1.domain.org,ldap2.domain.org:389"

## Phase 1 transform defaults...
```

EXAMPLE 1 A Sample ike.config File (Continued)

```

p1_lifetime_secs 14400
p1_nonce_len 20

## Parameters that may also show up in rules.

p1_xform { auth_method preshared oakley_group 5 auth_alg sha
           encr_alg 3des }
p2_pfs 2

### Now some rules...

{
  label "simple inheritor"
  local_id_type ip
  local_addr 10.1.1.1
  remote_addr 10.1.1.2
}

{
  # an index-only rule.  If I'm a receiver, and all I
  # have are index-only rules, what do I do about inbound IKE requests?
  # Answer:  Take them all!

  label "default rule"
  # Use whatever "host" (e.g. IP address) identity is appropriate
  local_id_type ipv4

  local_addr 0.0.0.0/0
  remote_addr 0.0.0.0/0

  p2_pfs 5

  # Now I'm going to have the p1_xforms
  p1_xform
  {auth_method preshared oakley_group 5 auth_alg md5 encr_alg blowfish }
  p1_xform
  {auth_method preshared oakley_group 5 auth_alg md5 encr_alg 3des }

  # After said list, another keyword (or a ')') will stop xform parsing.
}

{
  # Let's try something a little more conventional.

  label "host to .80 subnet"
  local_id_type ip
  local_id "10.1.86.51"

  remote_id "" # Take any, use remote_addr for access control.

  local_addr 10.1.86.51
  remote_addr 10.1.80.0/24

  p1_xform

```

EXAMPLE 1 A Sample ike.config File (Continued)

```

    { auth_method rsa_sig oakley_group 5 auth_alg md5 encr_alg 3des }
    p1_xform
    { auth_method rsa_sig oakley_group 5 auth_alg md5 encr_alg blowfish }
    p1_xform
    { auth_method rsa_sig oakley_group 5 auth_alg sha1 encr_alg 3des }
    p1_xform
    { auth_method rsa_sig oakley_group 5 auth_alg sha1 encr_alg blowfish }
  }
  {
    # How 'bout something with a different cert type and name?

    label "punchin-point"
    local_id_type mbox
    local_id "ipsec-wizard@domain.org"

    remote_id "10.5.5.128"

    local_addr 0.0.0.0/0
    remote_addr 10.5.5.128

    p1_xform
    { auth_method rsa_sig oakley_group 5 auth_alg md5 encr_alg blowfish }
  }

  {
    label "receiver side"

    remote_id "ipsec-wizard@domain.org"

    local_id_type ip
    local_id "10.5.5.128"

    local_addr 10.5.5.128
    remote_addr 0.0.0.0/0

    p1_xform
    { auth_method rsa_sig oakley_group 5 auth_alg md5 encr_alg blowfish }
    # NOTE: Specifying pre-shared null-and-voids the remote_id/local_id
    #        fields.
    p1_xform
    { auth_method preshared oakley_group 5 auth_alg md5 encr_alg blowfish }
  }

```

ike.preshared(4)

NAME ike.preshared – pre-shared keys file for IKE

SYNOPSIS /etc/inet/secret/ike.preshared

DESCRIPTION The /etc/inet/secret/ike.preshared file contains secret keying material that two IKE instances can use to authenticate each other. Because of the sensitive nature of this data, it is kept in the /etc/inet/secret directory, which is only accessible by root.

Pre-shared keys are delimited by open-curly-brace ({} and close-curly-brace (}) characters. There are five name-value pairs required inside a pre-shared key:

Name	Value	Example
localidtype	IP	localidtype IP
remoteidtype	IP	remoteidtype IP
localid	IP-address	localid 10.1.1.2
remoteid	IP-address	remoteid 10.1.1.3
key	hex-string	1234567890abcdef

Comment lines with # appearing in the first column are also legal.

Files in this format can also be used by the `ikeadm(1M)` command to load additional pre-shared keys into a running an `in.iked(1M)` process.

EXAMPLES **EXAMPLE 1** A Sample ike.preshared File

The following is an example of an `ike.preshared` file:

```
#
# Two pre-shared keys between myself, 10.1.1.2, and two remote
# hosts. Note that names are not allowed for IP addresses.
#
# A decent hex string can be obtained by performing:
#     od -x </dev/random | head
#
{
    localidtype IP
    localid 10.1.1.2
    remoteidtype IP
    remoteid 10.21.12.4
    key 4b656265207761732068657265210c0a
}

{
    localidtype IP
    localid 10.1.1.2
```

EXAMPLE 1 A Sample ike.preshared File (Continued)

```

remoteidtype IP
remoteid 10.9.1.25
key 536f20776572652042696c6c2c2052656e65652c20616e642043687269732e0a
}

```

SECURITY If this file is compromised, all IPsec security associations derived from secrets in this file will be compromised as well. The default permissions on ike.preshared are 0600. They should stay this way.

inetd.conf(4)

NAME	inetd.conf – Internet servers database										
SYNOPSIS	<pre>/etc/inet/inetd.conf /etc/inetd.conf</pre>										
DESCRIPTION	<p>The <code>inetd.conf</code> file contains the list of servers that <code>inetd(1M)</code> invokes when it receives an Internet request over a socket. Each server entry is composed of a single line of the form:</p> <pre>service-name endpoint-type protocol wait-status uid server-program \ server-arguments</pre> <p>Fields are separated by either SPACE or TAB characters. A '#' (number sign) indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines that search this file.</p> <p><i>service-name</i> The name of a valid service listed in the <code>services</code> file. For RPC services, the value of the <i>service-name</i> field consists of the RPC service name or program number, followed by a '/' (slash) and either a version number or a range of version numbers, for example, <code>rstatd/2-4</code>.</p> <p><i>endpoint-type</i> Can be one of:</p> <table><tr><td><code>stream</code></td><td>for a stream socket</td></tr><tr><td><code>dgram</code></td><td>for a datagram socket</td></tr><tr><td><code>raw</code></td><td>for a raw socket</td></tr><tr><td><code>seqpacket</code></td><td>for a sequenced packet socket</td></tr><tr><td><code>tli</code></td><td>for all TLI endpoints</td></tr></table> <p><i>protocol</i> A recognized protocol listed in the file <code>/etc/inet/protocols</code>. For servers capable of supporting TCP and UDP over IPv6, the following protocol types are also recognized:</p> <pre>tcp6 udp6 tcp6 and udp6 are not official protocols; accordingly, they are not listed in the /etc/inet/protocols file.</pre> <p>Here the <code>inetd</code> program uses an <code>AF_INET6</code> type socket endpoint. These servers can also handle incoming IPv4 client requests in addition to IPv6 client requests.</p> <p>For RPC services, the field consists of the string <code>rpc</code> followed by a '/' (slash) and either a '*' (asterisk), one or more nettypes, one or more netids, or a combination of nettypes and netids. Whatever the value, it is first</p>	<code>stream</code>	for a stream socket	<code>dgram</code>	for a datagram socket	<code>raw</code>	for a raw socket	<code>seqpacket</code>	for a sequenced packet socket	<code>tli</code>	for all TLI endpoints
<code>stream</code>	for a stream socket										
<code>dgram</code>	for a datagram socket										
<code>raw</code>	for a raw socket										
<code>seqpacket</code>	for a sequenced packet socket										
<code>tli</code>	for all TLI endpoints										

		<p>treated as a nettype. If it is not a valid nettype, then it is treated as a netid. For example, <code>rpc/*</code> for an RPC service using all the transports supported by the system (the list can be found in the <code>/etc/netconfig</code> file), equivalent to saying <code>rpc/visible rpc/ticots</code> for an RPC service using the Connection-Oriented Transport Service.</p>
	<i>wait-status</i>	<p>This field has values <code>wait</code> or <code>nowait</code>. This entry specifies whether the server that is invoked by <code>inetd</code> will take over the listening socket associated with the service, and whether once launched, <code>inetd</code> will wait for that server to exit, if ever, before it resumes listening for new service requests. The <i>wait-status</i> for datagram servers must be set to <code>wait</code>, as they are always invoked with the original datagram socket that will participate in delivering the service bound to the specified service. They do not have separate "listening" and "accepting" sockets. Accordingly, do not configure UDP services as <code>nowait</code>. This causes a race condition by which the <code>inetd</code> program selects on the socket and the server program reads from the socket. Many server programs will be forked, and performance will be severely compromised. Connection-oriented services such as TCP stream services can be designed to be either <code>wait</code> or <code>nowait</code> status.</p>
	<i>uid</i>	<p>The user ID under which the server should run. This allows servers to run with access privileges other than those for root.</p>
	<i>server-program</i>	<p>Either the pathname of a server program to be invoked by <code>inetd</code> to perform the requested service, or the value <code>internal</code> if <code>inetd</code> itself provides the service.</p>
	<i>server-arguments</i>	<p>If a server must be invoked with command line arguments, the entire command line (including argument 0) must appear in this field (which consists of all remaining words in the entry). If the server expects <code>inetd</code> to pass it the address of its peer, for compatibility with 4.2BSD executable daemons, then the first argument to the command should be specified as <code>%A</code>. No more than 20 arguments are allowed in this field. The <code>%A</code> argument is implemented only for services whose <i>wait-status</i> value is <code>wait</code>.</p>
FILES	<code>/etc/netconfig</code>	network configuration file
	<code>/etc/inet/protocols</code>	Internet protocols

inetd.conf(4)

`/etc/inet/services` Internet network services

SEE ALSO `rlogin(1)`, `rsh(1)`, `in.tftpd(1M)`, `inetd(1M)`, `services(4)`

NOTES `/etc/inet/inetd.conf` is the official SVR4 name of the `inetd.conf` file. The symbolic link `/etc/inetd.conf` exists for BSD compatibility.

NAME	inet_type – default Internet protocol type						
SYNOPSIS	/etc/default/inet_type						
DESCRIPTION	<p>The <code>inet_type</code> file defines the default IP protocol to use. Currently this file is only used by the <code>ifconfig(1M)</code> and <code>netstat(1M)</code> commands.</p> <p>The <code>inet_type</code> file can contain a number of <code><variable>=<value></code> lines. Currently, the only variable defined is <code>DEFAULT_IP</code>, which can be assigned a value of <code>IP_VERSION4</code>, <code>IP_VERSION6</code>, or <code>BOTH</code>.</p> <p>The output displayed by the <code>ifconfig</code> and <code>netstat</code> commands can be controlled by the value of <code>DEFAULT_IP</code> set in <code>inet_type</code> file. By default, both commands display the IPv4 and IPv6 information available on the system. The user can choose to suppress display of IPv6 information by setting the value of <code>DEFAULT_IP</code>. The following shows the possible values for <code>DEFAULT_IP</code> and the resulting <code>ifconfig</code> and <code>netstat</code> output that will be displayed:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>IP_VERSION4</code></td> <td>Displays only IPv4 related information. The output displayed is backward compatible with older versions of the <code>ifconfig(1M)</code> and <code>netstat(1M)</code> commands.</td> </tr> <tr> <td><code>IP_VERSION6</code></td> <td>Displays both IPv4 and IPv6 related information for <code>ifconfig</code> and <code>netstat</code>.</td> </tr> <tr> <td><code>BOTH</code></td> <td>Displays both IPv4 and IPv6 related information for <code>ifconfig</code> and <code>netstat</code>.</td> </tr> </table> <p>The command-line options to the <code>ifconfig</code> and <code>netstat</code> commands override the effect of <code>DEFAULT_IP</code> as set in the <code>inet_type</code> file. For example, even if the value of <code>DEFAULT_IP</code> is <code>IP_VERSION4</code>, the command</p> <pre>example% ifconfig -a6</pre> <p>will display all IPv6 interfaces.</p>	<code>IP_VERSION4</code>	Displays only IPv4 related information. The output displayed is backward compatible with older versions of the <code>ifconfig(1M)</code> and <code>netstat(1M)</code> commands.	<code>IP_VERSION6</code>	Displays both IPv4 and IPv6 related information for <code>ifconfig</code> and <code>netstat</code> .	<code>BOTH</code>	Displays both IPv4 and IPv6 related information for <code>ifconfig</code> and <code>netstat</code> .
<code>IP_VERSION4</code>	Displays only IPv4 related information. The output displayed is backward compatible with older versions of the <code>ifconfig(1M)</code> and <code>netstat(1M)</code> commands.						
<code>IP_VERSION6</code>	Displays both IPv4 and IPv6 related information for <code>ifconfig</code> and <code>netstat</code> .						
<code>BOTH</code>	Displays both IPv4 and IPv6 related information for <code>ifconfig</code> and <code>netstat</code> .						
EXAMPLES	<p>EXAMPLE 1 Suppressing IPv6 Related Output</p> <p>This is what the <code>inet_type</code> file must contain if you want to suppress IPv6 related output:</p> <pre>DEFAULT_IP=IP_VERSION4</pre>						
SEE ALSO	<code>ifconfig(1M)</code> , <code>netstat(1M)</code>						

init.d(4)

NAME	init.d – initialization and termination scripts for changing init states
SYNOPSIS	/etc/init.d
DESCRIPTION	<p>/etc/init.d is a directory containing initialization and termination scripts for changing init states. These scripts are linked when appropriate to files in the rc?.d directories, where '?' is a single character corresponding to the init state. See init(1M) for definitions of the states.</p> <p>File names in rc?.d directories are of the form [SK]nn<init.d filename>, where S means start this job, K means kill this job, and nn is the relative sequence number for killing or starting the job.</p> <p>When entering a state (init S,0,2,3,etc.) the rc[S0-6] script executes those scripts in /etc/rc[S0-6].d that are prefixed with K followed by those scripts prefixed with S. When executing each script in one of the /etc/rc[S0-6] directories, the /sbin/rc[S0-6] script passes a single argument. It passes the argument 'stop' for scripts prefixed with K and the argument 'start' for scripts prefixed with S. There is no harm in applying the same sequence number to multiple scripts. In this case the order of execution is deterministic but unspecified.</p> <p>Guidelines for selecting sequence numbers are provided in README files located in the directory associated with that target state. For example, /etc/rc[S0-6].d/README. Absence of a README file indicates that there are currently no established guidelines.</p>
EXAMPLES	<p>EXAMPLE 1 Example of /sbin/rc2.</p> <p>When changing to init state 2 (multi-user mode, network resources not exported), /sbin/rc2 is initiated by the init process. The following steps are performed by /sbin/rc2.</p> <ol style="list-style-type: none">1. In the directory /etc/rc2.d are files used to stop processes that should not be running in state 2. The filenames are prefixed with K. Each K file in the directory is executed (by /sbin/rc2) in alphanumeric order when the system enters init state 2. See example below.2. Also in the rc2.d directory are files used to start processes that should be running in state 2. As in Step 1, each S file is executed. <p>Assume the file /etc/init.d/netdaemon is a script that will initiate networking daemons when given the argument 'start', and will terminate the daemons if given the argument 'stop'. It is linked to /etc/rc2.d/S68netdaemon, and to /etc/rc0.d/K67netdaemon. The file is executed by /etc/rc2.d/S68netdaemon start when init state 2 is entered and by /etc/rc0.d/K67netdaemon stop when shutting the system down.</p>
SEE ALSO	init(1M)

NOTES /sbin/rc2 has references to the obsolescent rc.d directory. These references are for compatibility with old INSTALL scripts. New INSTALL scripts should use the init.d directory for related executables. The same is true for the shutdown.d directory.

inittab(4)

NAME	inittab – script for init
DESCRIPTION	<p>The file <code>/etc/inittab</code> controls process dispatching by <code>init</code>. The processes most typically dispatched by <code>init</code> are daemons.</p> <p>The <code>inittab</code> file is composed of entries that are position dependent and have the following format:</p> <pre><i>id</i> : <i>rstate</i> : <i>action</i> : <i>process</i></pre> <p>Each entry is delimited by a newline; however, a backslash (<code>\</code>) preceding a newline indicates a continuation of the entry. Up to 512 characters for each entry are permitted. Comments may be inserted in the <i>process</i> field using the convention for comments described in <code>sh(1)</code>. There are no limits (other than maximum entry size) imposed on the number of entries in the <code>inittab</code> file. The entry fields are:</p> <p><i>id</i></p> <p>One to four characters used to uniquely identify an entry. Do not use the characters "r" or "t" as the first or only character in this field. These characters are reserved for the use of <code>rlogin(1)</code> and <code>telnet(1)</code>.</p> <p><i>rstate</i></p> <p>Define the run level in which this entry is to be processed. Run-levels effectively correspond to a configuration of processes in the system. That is, each process spawned by <code>init</code> is assigned a run level(s) in which it is allowed to exist. The run levels are represented by a number ranging from 0 through 6. For example, if the system is in run level 1, only those entries having a 1 in the <i>rstate</i> field are processed.</p> <p>When <code>init</code> is requested to change run levels, all processes that do not have an entry in the <i>rstate</i> field for the target run level are sent the warning signal <code>SIGTERM</code> and allowed a 5-second grace period before being forcibly terminated by the kill signal <code>SIGKILL</code>. The <i>rstate</i> field can define multiple run levels for a process by selecting more than one run level in any combination from 0 through 6. If no run level is specified, then the process is assumed to be valid at all run levels 0 through 6.</p> <p>There are three other values, <i>a</i>, <i>b</i> and <i>c</i>, which can appear in the <i>rstate</i> field, even though they are not true run levels. Entries which have these characters in the <i>rstate</i> field are processed only when an <code>init</code> or <code>telinit</code> process requests them to be run (regardless of the current run level of the system). See <code>init(1M)</code>. These differ from run levels in that <code>init</code> can never enter run level <i>a</i>, <i>b</i> or <i>c</i>. Also, a request for the execution of any of these processes does not change the current run level. Furthermore, a process started by an <i>a</i>, <i>b</i> or <i>c</i> command is not killed when <code>init</code> changes levels. They are killed only if their line in <code>inittab</code> is marked <code>off</code> in the <i>action</i> field, their line is deleted entirely from <code>inittab</code>, or <code>init</code> goes into single-user state.</p>

action

Key words in this field tell `init` how to treat the process specified in the *process* field. The actions recognized by `init` are as follows:

`respawn`

If the process does not exist, then start the process; do not wait for its termination (continue scanning the `inittab` file), and when the process dies, restart the process. If the process currently exists, do nothing and continue scanning the `inittab` file.

`wait`

When `init` enters the run level that matches the entry's *rstate*, start the process and wait for its termination. All subsequent reads of the `inittab` file while `init` is in the same run level cause `init` to ignore this entry.

`once`

When `init` enters a run level that matches the entry's *rstate*, start the process, do not wait for its termination. When it dies, do not restart the process. If `init` enters a new run level and the process is still running from a previous run level change, the program is not restarted.

`boot`

The entry is to be processed only at `init`'s boot-time read of the `inittab` file. `init` is to start the process and not wait for its termination; when it dies, it does not restart the process. In order for this instruction to be meaningful, the *rstate* should be the default or it must match `init`'s run level at boot time. This action is useful for an initialization function following a hardware reboot of the system.

`bootwait`

The entry is to be processed the first time `init` goes from single-user to multi-user state after the system is booted. (If `initdefault` is set to 2, the process runs right after the boot.) `init` starts the process, waits for its termination and, when it dies, does not restart the process.

`powerfail`

Execute the process associated with this entry only when `init` receives a power fail signal, `SIGPWR` (see `signal(3C)`).

`powerwait`

Execute the process associated with this entry only when `init` receives a power fail signal, `SIGPWR`, and wait until it terminates before continuing any processing of `inittab`.

`off`

If the process associated with this entry is currently running, send the warning signal `SIGTERM` and wait 5 seconds before forcibly terminating the process with the kill signal `SIGKILL`. If the process is nonexistent, ignore the entry.

`ondemand`

This instruction is really a synonym for the `respawn` action. It is functionally identical to `respawn` but is given a different keyword in order to divorce its

inittab(4)

association with run levels. This instruction is used only with the *a*, *b* or *c* values described in the *rstate* field.

initdefault

An entry with this action is scanned only when *init* is initially invoked. *init* uses this entry to determine which run level to enter initially. It does this by taking the highest run level specified in the *rstate* field and using that as its initial state. If the *rstate* field is empty, this is interpreted as 0123456 and *init* will enter run level 6. This will cause the system to loop (it will go to firmware and reboot continuously). Additionally, if *init* does not find an *initdefault* entry in *inittab*, it requests an initial run level from the user at reboot time.

sysinit

Entries of this type are executed before *init* tries to access the console (that is, before the *Console Login:* prompt). It is expected that this entry will be used only to initialize devices that *init* might try to ask the run level question. These entries are executed and *init* waits for their completion before continuing.

process

Specify a command to be executed. The entire *process* field is prefixed with *exec* and passed to a forked *sh* as *sh -c 'exec command'*. For this reason, any legal *sh* syntax can appear in the *process* field.

NAME	ipnodes – local database associating names of nodes with IP addresses
SYNOPSIS	<code>/etc/inet/ipnodes</code>
DESCRIPTION	<p>The <code>ipnodes</code> file is a local database that associates the names of nodes with their Internet Protocol (IP) addresses. IP addresses can be either an IPv4 or an IPv6 address. The <code>ipnodes</code> file can be used in conjunction with, or instead of, other <code>ipnodes</code> databases, including the Domain Name System (DNS), the NIS <code>ipnodes</code> map, and the NIS+ <code>ipnodes</code> table. Programs use library interfaces to access information in the <code>ipnodes</code> file.</p> <p>The <code>ipnodes</code> file has one entry for each IP address of each node. If a node has more than one IP address, it will have one entry for each, on consecutive lines. The format of each line is:</p> <pre>IP-address official-node-name nicknames...</pre> <p>Items are separated by any number of SPACE and/or TAB characters. The first item on a line is the node's IP address. The second entry is the node's official name. Subsequent entries on the same line are alternative names for the same machine, or "nicknames." Nicknames are optional.</p> <p>For a node with more than one IP address, consecutive entries for these addresses may contain the same or differing nicknames. Different nicknames are useful for assigning distinct names to different addresses.</p> <p>A call to <code>getipnodebyname(3SOCKET)</code> returns a <code>hostent</code> structure containing the union of all addresses and nicknames from each line containing a matching official name or nickname.</p> <p>A '#' indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines that search the file.</p> <p>Network addresses are written in one of two ways:</p> <ul style="list-style-type: none"> ■ The conventional "decimal dot" notation and interpreted using the <code>inet_addr</code> routine from the Internet address manipulation library, <code>inet(3SOCKET)</code>. ■ The IP Version 6 protocol [IPv6], defined in <i>RFC 1884</i> and interpreted using the <code>inet_pton()</code> routine from the Internet address manipulation library. See <code>inet(3SOCKET)</code>. <p>These interfaces supports node names as defined in <i>Internet RFC 952</i> which states:</p> <p>A "name" (Net, Host, Gateway, or Domain name) is a text string up to 24 characters drawn from the alphabet (A-Z), digits (0-9), minus sign (-), and period (.). Note that periods are only allowed when they serve to delimit components of "domain style names". (See <i>RFC 921, "Domain Name System Implementation Schedule,"</i> for background). No blank or space characters are permitted as part of a name. No distinction is made between upper and lower case. The first character must be an alpha character. The last character must not be a minus sign or period.</p>

ipnodes(4)

Although the interface accepts node names longer than 24 characters for the node portion (exclusive of the domain component), choosing names for nodes that adhere to the 24 character restriction will insure maximum interoperability on the Internet.

A node which serves as a GATEWAY should have "-GATEWAY" or "-GW" as part of its name. Nodes which do not serve as Internet gateways should not use "-GATEWAY" and "-GW" as part of their names. A node that is a TAC should have "-TAC" as the last part of its node name, if it is a DoD node. Single character names or nicknames are not allowed.

RFC 952 has been modified by *RFC 1123* to relax the restriction on the first character being a digit.

EXAMPLES **EXAMPLE 1** A Typical Line from the ipnodes File

The following is a typical line from the ipnodes file:

```
2::56:a00:20ff:fe7b:b667      foo      # John Smith
```

SEE ALSO `in.named(1M)`, `getipnodebyname(3SOCKET)`, `inet(3SOCKET)`, `nsswitch.conf(4)`, `resolv.conf(4)`, `hosts(4)`

Braden, B., editor, *RFC 1123, Requirements for Internet Hosts – Application and Support*, Network Working Group, October, 1989.

Harrenstien, K., Stahl, M., and Feinler, E., *RFC 952, DOD INTERNET HOST TABLE SPECIFICATION*, Network Working Group, October 1985.

Hinden, R., and Deering, S., editors, *RFC 1884, IP Version 6 Addressing Architecture*, Network Working Group, December, 1995.

Postel, Jon, *RFC 921, Domain Name System Implementation Schedule — Revised*, Network Working Group, October 1984.

NOTES IPv4 addresses can be defined in the ipnodes file or in the hosts file. See `hosts(4)`. The ipnodes file will be searched for IPv4 addresses when using the `getipnodebyname(3SOCKET)` API. If no matching IPv4 addresses are found in the ipnodes file, then the hosts file will be searched. To prevent delays in name resolution and to keep `/etc/inet/ipnodes` and `/etc/inet/hosts` synchronized, IPv4 addresses defined in the hosts file should be copied to the ipnodes file.

NAME	issue – issue identification file
DESCRIPTION	The file <code>/etc/issue</code> contains the issue or project identification to be printed as a login prompt. <code>issue</code> is an ASCII file that is read by program <code>getty</code> and then written to any terminal spawned or respawned from the <code>lines</code> file.
FILES	<code>/etc/issue</code>
SEE ALSO	<code>login(1)</code>

kadm5.acl(4)

NAME	kadm5.acl – Kerberos access control list (ACL) file																		
SYNOPSIS	<code>/etc/krb5/kadm5.acl</code>																		
DESCRIPTION	<p>The ACL file is used by the <code>kadmind(1M)</code> command to determine which principals are allowed to perform Kerberos administration actions. For operations that affect principals, the ACL file also controls which principals can operate on which other principals. The location of the ACL file is determined by the <code>acl_file</code> configuration variable in the <code>kdc.conf(4)</code> file. The default location is <code>/etc/krb5/kadm5.acl</code>.</p> <p>The ACL file can contain comment lines, null lines, or lines that contain ACL entries. Comment lines start with the pound sign (#) and continue until the end of the line.</p> <p>The order of entries is significant. The first matching entry specifies the principal on which the control access applies, whether it is on just the principal or on the principal when it operates on a target principal.</p> <p>Lines containing ACL entries must have the following format:</p> <pre><i>principal operation-mask [operation-target]</i></pre> <p><i>principal</i></p> <p>Specifies the principal on which the <i>operation-mask</i> applies. Can specify either a partially or fully qualified Kerberos principal name. Each component of the name can be substituted with a wildcard, using the asterisk (*) character.</p> <p><i>operation-mask</i></p> <p>Specifies what operations can or cannot be performed by a principal matching a particular entry. Specify <i>operation-mask</i> as one or more <i>privileges</i>.</p> <p>A <i>privilege</i> is a string of one or more of the following characters: a, A, c, C, d, D, i, I, l, L, m, M, x, or *. Generally, if the character is lowercase, the privilege is allowed and if the character is uppercase, the operation is disallowed. The x and * characters are exceptions to the uppercase convention.</p> <p>The following <i>privileges</i> are supported:</p> <table><tr><td>a</td><td>Allows the addition of principals or policies in the database.</td></tr><tr><td>A</td><td>Disallows the addition of principals or policies in the database.</td></tr><tr><td>c</td><td>Allows the changing of passwords for principals in the database.</td></tr><tr><td>C</td><td>Disallows the changing of passwords for principals in the database.</td></tr><tr><td>d</td><td>Allows the deletion of principals or policies in the database.</td></tr><tr><td>D</td><td>Disallows the deletion of principals or policies in the database.</td></tr><tr><td>i</td><td>Allows inquiries to the database.</td></tr><tr><td>I</td><td>Disallows inquiries to the database.</td></tr><tr><td>l</td><td>Allows the listing of principals or policies in the database.</td></tr></table>	a	Allows the addition of principals or policies in the database.	A	Disallows the addition of principals or policies in the database.	c	Allows the changing of passwords for principals in the database.	C	Disallows the changing of passwords for principals in the database.	d	Allows the deletion of principals or policies in the database.	D	Disallows the deletion of principals or policies in the database.	i	Allows inquiries to the database.	I	Disallows inquiries to the database.	l	Allows the listing of principals or policies in the database.
a	Allows the addition of principals or policies in the database.																		
A	Disallows the addition of principals or policies in the database.																		
c	Allows the changing of passwords for principals in the database.																		
C	Disallows the changing of passwords for principals in the database.																		
d	Allows the deletion of principals or policies in the database.																		
D	Disallows the deletion of principals or policies in the database.																		
i	Allows inquiries to the database.																		
I	Disallows inquiries to the database.																		
l	Allows the listing of principals or policies in the database.																		

L	Disallows the listing of principals or policies in the database.
m	Allows the modification of principals or policies in the database.
M	Disallows the modification of principals or policies in the database.
x	Short for specifying privileges a, d,m,c,i, and l. The same as *.
*	Short for specifying privileges a, d,m,c,i, and l. The same as x.

operation-target

Optional. When specified, the *privileges* apply to the *principal* when it operates on the *operation-target*. For the *operation-target*, you can specify a partially or fully qualified Kerberos principal name. Each component of the name can be substituted by a wildcard, using the asterisk (*) character.

EXAMPLES**EXAMPLE 1** Specifying a Standard, Fully Qualified Name

The following ACL entry specifies a standard, fully qualified name:

```
user/instance@realm adm
```

The *operation-mask* applies only to the `user/instance@realm` principal and specifies that the principal can add, delete, or modify principals and policies, but it cannot change passwords.

EXAMPLE 2 Specifying a Standard Fully Qualified Name and Target

The following ACL entry specifies a standard, fully qualified name:

```
user/instance@realm cim service/instance@realm
```

The *operation-mask* applies only to the `user/instance@realm` principal operating on the `service/instance@realm` target, and specifies that the principal can change the target's password, request information about the target, and modify it.

EXAMPLE 3 Specifying a Name Using a Wildcard

The following ACL entry specifies a name using a wildcard:

```
user/*@realm ac
```

The *operation-mask* applies to all principals in realm `realm` whose first component is `user` and specifies that the principals can add principals and change passwords.

EXAMPLE 4 Specifying a Name Using a Wildcard and a Target

The following ACL entry specifies a name using a wildcard and a target:

```
user/*@realm i */instance@realm
```

The *operation-mask* applies to all principals in realm `realm` whose first component is `user` and specifies that the principals can perform inquiries on principals whose

kadm5.acl(4)

EXAMPLE 4 Specifying a Name Using a Wildcard and a Target *(Continued)*

second component is instance and realm is realm.

FILES /etc/krb5/kdc.conf
KDC configuration information.

SEE ALSO kpasswd(1), gkadmin(1M), kadmind(1M), kadmin.local(1M), kdb5_util(1M),
kdc.conf(4), SEAM(5)

NAME	kdc.conf – Key Distribution Center (KDC) configuration file
SYNOPSIS	<code>/etc/krb5/kdc.conf</code>
DESCRIPTION	<p>The <code>kdc.conf</code> file contains KDC configuration information, including defaults used when issuing Kerberos tickets. This file must reside on all KDC servers. After you make any changes to the <code>kdc.conf</code> file, stop and restart the <code>krb5kdc</code> daemon on the KDC for the changes to take effect.</p> <p>The format of the <code>kdc.conf</code> consists of section headings in square brackets (<code>[]</code>). Each section contains zero or more configuration variables (called relations), of the form of:</p> <pre>relation = relation-value or relation-subsection = { relation = relation-value relation = relation-value }</pre> <p>The <code>kdc.conf</code> file contains one or more of the following three sections:</p> <p><code>kdcdefaults</code> Contains default values for overall behavior of the KDC.</p> <p><code>realms</code> Contains subsections for Kerberos realms, where <i>relation-subsection</i> is the name of a realm. Each subsection contains relations that define KDC properties for that particular realm, including where to find the Kerberos servers for that realm.</p> <p><code>logging</code> Contains relations that determine how Kerberos programs perform logging.</p> <p>The <code>kdcdefaults</code> Section</p> <p>The following relation can be defined in the <code>[kdcdefaults]</code> section:</p> <p><code>kdc_ports</code> This relation lists the ports on which the Kerberos server should listen by default. This list is a comma-separated list of integers. If this relation is not specified, the Kerberos server listens on port 750 and port 88.</p> <p>The <code>realms</code> Section</p> <p>This section contains subsections for Kerberos realms, where <i>relation-subsection</i> is the name of a realm. Each subsection contains relations that define KDC properties for that particular realm.</p> <p>The following relations can be specified in each subsection:</p> <p><code>acl_file</code> (string) Location of the Kerberos V5 access control list (ACL) file that <code>kadmin</code> uses to determine the privileges allowed to each principal on the database. The default location is <code>/etc/krb5/kadm5.acl</code>.</p>

kdc.conf(4)

`admin_keytab`
(string) Location of the `keytab` file that `kadmin` uses to authenticate to the database. The default location is `/etc/krb5/kadm5.keytab`.

`database_name`
(string) Location of the Kerberos database for this realm. The default location is `/var/krb5/principal.db`.

`default_principal_expiration`
(absolute time string) The default expiration date of principals created in this realm. See the `Time Format` section in `kinit(1)` for the valid absolute time formats you can use for `default_principal_expiration`.

`default_principal_flags`
(flag string) The default attributes of principals created in this realm.

`dict_file`
(string) Location of the dictionary file containing strings that are not allowed as passwords. A principal with any password policy is not allowed to select a password in the dictionary. The default location is `/var/krb5/kadm5.dict`.

`encryption_type`
(encryption type string) The encryption type used for this realm. The `des-cbc-crc` and `des-cbc-md5` encryption types are supported at this time.

`kadmind_port`
(port number) The port that the `kadmind` daemon is to listen on for this realm. The assigned port for `kadmind` is 749.

`key_stash_file`
(string) Location where the master key has been stored (by `kdb5_util stash`). The default location is `/var/krb5/.k5.realm`, where `realm` is the Kerberos realm.

`kdc_ports`
(string) The list of ports that the KDC listens on for this realm. By default, the value of `kdc_ports` as specified in the `[kdcdefaults]` section is used.

`master_key_name`
(string) The name of the master key.

`master_key_type`
(key type string) The master key's key type. Only `des-cbc-crc` is supported at this time.

`max_life`
(delta time string) The maximum time period for which a ticket is valid in this realm. See the `Time Format` section in `kinit(1)` for the valid time duration formats you can use for `max_life`.

`max_renewable_life`
(delta time string) The maximum time period during which a valid ticket can be renewed in this realm. See the `Time Format` section in `kinit(1)` for the valid time duration formats you can use for `max_renewable_life`.

**The logging
Section****supported_enctypes**

List of key/salt strings. The default key/salt combinations of principals for this realm. The key is separated from the salt by a period (.). Multiple key/salt strings can be used by separating each string with a space. The salt is additional information encoded within the key that tells what kind of key it is. Only the *normal* salt is supported at this time, for example, *des-cbc-crc:normal*.

This section indicates how Kerberos programs perform logging. The same relation can be repeated if you want to assign it multiple logging methods. The following relations can be defined in the [logging] section:

kdc

Specifies how the KDC is to perform its logging. The default is
FILE:/var/krb5/kdc.log.

admin_server

Specifies how the administration server is to perform its logging. The default is
FILE:/var/krb5/kadmin.log.

default

Specifies how to perform logging in the absence of explicit specifications.

The [logging] relations can have the following values:

FILE:*filename*

or

FILE=*filename*

This value causes the entity's logging messages to go to the specified file. If the '=' form is used, the file is overwritten. If the ':' form is used, the file is appended to.

STDERR

This value sends the entity's logging messages to its standard error stream.

CONSOLE

This value sends the entity's logging messages to the console, if the system supports it.

DEVICE=*devicename*

This sends the entity's logging messages to the specified device.

SYSLOG [:*severity* [:*facility*]]

This sends the entity's logging messages to the system log.

The *severity* argument specifies the default severity of system log messages. This default can be any of the following severities supported by the `syslog(3C)` call, minus the `LOG_` prefix: `LOG_EMERG`, `LOG_ALERT`, `LOG_CRIT`, `LOG_ERR`, `LOG_WARNING`, `LOG_NOTICE`, `LOG_INFO`, and `LOG_DEBUG`. For example, a value of `CRIT` would specify `LOG_CRIT` severity.

kdc.conf(4)

The *facility* argument specifies the facility under which the messages are logged. This can be any of the following facilities supported by the `syslog(3C)` call minus the `LOG_` prefix: `LOG_KERN`, `LOG_USER`, `LOG_MAIL`, `LOG_DAEMON`, `LOG_AUTH`, `LOG_LPR`, `LOG_NEWS`, `LOG_UUCP`, `LOG_CRON`, and `LOG_LOCAL0` through `LOG_LOCAL7`.

If no severity is specified, the default is `ERR`. If no facility is specified, the default is `AUTH`.

In the following example, the logging messages from the KDC go to the console and to the system log under the facility `LOG_DAEMON` with default severity of `LOG_INFO`; the logging messages from the administration server are appended to the `/var/krb5/kadmin.log` file and sent to the `/dev/tty04` device.

```
[logging]
kdc = CONSOLE
kdc = SYSLOG:INFO:DAEMON
admin_server = FILE:/export/logging/kadmin.log
admin_server = DEVICE=/dev/tty04
```

EXAMPLES **EXAMPLE 1** Sample `kdc.conf` File

The following is an example of a `kdc.conf` file:

```
[kdcdefaults]
  kdc_ports = 88

[realms]
  ATHENA.MIT.EDU = {
    kadmind_port = 749
    max_life = 10h 0m 0s
    max_renewable_life = 7d 0h 0m 0s
    master_key_type = des-cbc-crc
    supported_encetypes = des-cbc-crc:normal
  }

[logging]
  kdc = FILE:/export/logging/kdc.log
  admin_server = FILE:/export/logging/kadmin.log
```

FILES

- `/etc/krb5/kadm5.acl`
List of principals and their `kadmin` administrative privileges.
- `/etc/krb5/kadm5.keytab`
Keytab for `kadmin/admin` Principal.
- `/var/krb5/principal.db`
Kerberos principal database.
- `/var/krb5/kadm5.dict`
Dictionary of strings explicitly disallowed as passwords.
- `/var/krb5/kdc.log`
KDC logging file.

kdc.conf(4)

/var/krb5/kadmin.log

Kerberos administration server logging file.

SEE ALSO kpasswd(1), gkadmin(1M), kadmind(1M), kadmin.local(1M), kdb5_util(1M), syslog(3C), kadm5.acl(4), SEAM(5)

keytables(4)

NAME	keytables – keyboard table descriptions for loadkeys and dumpkeys														
DESCRIPTION	<p>These files are used by <code>loadkeys(1)</code> to modify the translation tables used by the keyboard streams module and generated by (see <code>loadkeys(1)</code>) from those translation tables.</p> <p>Any line in the file beginning with <code>#</code> is a comment, and is ignored. <code>#</code> is treated specially only at the beginning of a line.</p> <p>Other lines specify the values to load into the tables for a particular keystation. The format is either:</p> <p><code>key number list_of_entries</code></p> <p>or</p> <p><code>swap number1 with number2</code></p> <p>or</p> <p><code>key number1 same as number2</code></p> <p>or a blank line, which is ignored.</p> <p><code>key number list_of_entries</code></p> <p>sets the entries for keystation <i>number</i> from the list given. An entry in that list is of the form</p> <p><code>tablename code</code></p> <p>where <i>tablename</i> is the name of a particular translation table, or <code>all</code>. The translation tables are:</p> <table><tr><td><code>base</code></td><td>entry when no shifts are active</td></tr><tr><td><code>shift</code></td><td>entry when "Shift" key is down</td></tr><tr><td><code>caps</code></td><td>entry when "Caps Lock" is in effect</td></tr><tr><td><code>ctrl</code></td><td>entry when "Control" is down</td></tr><tr><td><code>altg</code></td><td>entry when "Alt Graph" is down</td></tr><tr><td><code>numl</code></td><td>entry when "Num Lock" is in effect</td></tr><tr><td><code>up</code></td><td>entry when a key goes up</td></tr></table> <p>All tables other than <code>up</code> refer to the action generated when a key goes down. Entries in the <code>up</code> table are used only for shift keys, since the shift in question goes away when the key goes up, except for keys such as "Caps Lock" or "Num Lock"; the keyboard streams module makes the key look as if it were a latching key.</p>	<code>base</code>	entry when no shifts are active	<code>shift</code>	entry when "Shift" key is down	<code>caps</code>	entry when "Caps Lock" is in effect	<code>ctrl</code>	entry when "Control" is down	<code>altg</code>	entry when "Alt Graph" is down	<code>numl</code>	entry when "Num Lock" is in effect	<code>up</code>	entry when a key goes up
<code>base</code>	entry when no shifts are active														
<code>shift</code>	entry when "Shift" key is down														
<code>caps</code>	entry when "Caps Lock" is in effect														
<code>ctrl</code>	entry when "Control" is down														
<code>altg</code>	entry when "Alt Graph" is down														
<code>numl</code>	entry when "Num Lock" is in effect														
<code>up</code>	entry when a key goes up														

A table name of `all` indicates that the entry for all tables should be set to the specified value, with the following exception: for entries with a value other than `hole`, the entry for the `numl` table should be set to `nonl`, and the entry for the `up` table should be set to `nop`.

The *code* specifies the effect of the key in question when the specified shift key is down. A *code* consists of either:

- A character, which indicates that the key should generate the given character. The character can either be a single character, a single character preceded by `^` which refers to a "control character" (for instance, `^c` is control-C), or a C-style character constant enclosed in single quote characters (`'`), which can be expressed with C-style escape sequences such as `\r` for RETURN or `\000` for the null character. Note that the single character may be any character in an 8-bit character set, such as ISO 8859/1.
- A string, consisting of a list of characters enclosed in double quote characters (`"`). Note that the use of the double quote character means that a *code* of double quote must be enclosed in single quotes.
- One of the following expressions:

<code>shiftkeys+leftshift</code>	the key is to be the left-hand "Shift" key
<code>shiftkeys+rightshift</code>	the key is to be the right-hand "Shift" key
<code>shiftkeys+leftctrl</code>	the key is to be the left-hand "Control" key
<code>shiftkeys+rightctrl</code>	the key is to be the right-hand "Control" key
<code>shiftkeys+alt</code>	the key is to be the "Alt" shift key
<code>shiftkeys+altgraph</code>	the key is to be the "Alt Graph" shift key
<code>shiftkeys+capslock</code>	the key is to be the "Caps Lock" key
<code>shiftkeys+shiftlock</code>	the key is to be the "Shift Lock" key
<code>shiftkeys+numlock</code>	the key is to be the "Num Lock" key
<code>buckybits+systembit</code>	the key is to be the "Stop" key in SunView; this is normally the L1 key, or the SETUP key on the VT100 keyboard
<code>buckybits+metabit</code>	the key is to be the "meta" key. That is, the "Left" or "Right" key on a Sun-2 or Sun-3 keyboard or the "diamond" key on a Sun-4 keyboard
<code>compose</code>	the key is to be the "Compose" key
<code>ctrlq</code>	on the "VT100" keyboard, the key is to transmit the control-Q character (this would be the entry for the "Q" key in the <code>ctrl</code> table)

keytables(4)

<code>ctrls</code>	on the "VT100" keyboard, the key is to transmit the control-S character (this would be the entry for the "S" key in the <code>ctrl</code> table)
<code>noscroll</code>	on the "VT100" keyboard, the key is to be the "No Scroll" key
<code>string+uparrow</code>	the key is to be the "up arrow" key
<code>string+downarrow</code>	the key is to be the "down arrow" key
<code>string+leftarrow</code>	the key is to be the "left arrow" key
<code>string+rightrightarrow</code>	the key is to be the "right arrow" key
<code>string+homearrow</code>	the key is to be the "home" key
<code>fa_acute</code>	the key is to be the acute accent "floating accent" key
<code>fa_cedilla</code>	the key is to be the cedilla "floating accent" key
<code>fa_cflex</code>	the key is to be the circumflex "floating accent" key
<code>fa_grave</code>	the key is to be the grave accent "floating accent" key
<code>fa_tilde</code>	the key is to be the tilde "floating accent" key
<code>fa_umlaut</code>	the key is to be the umlaut "floating accent" key
<code>nonl</code>	this is used only in the Num Lock table; the key is not to be affected by the state of Num Lock
<code>pad0</code>	the key is to be the "0" key on the numeric keypad
<code>pad1</code>	the key is to be the "1" key on the numeric keypad
<code>pad2</code>	the key is to be the "2" key on the numeric keypad
<code>pad3</code>	the key is to be the "3" key on the numeric keypad
<code>pad4</code>	the key is to be the "4" key on the numeric keypad
<code>pad5</code>	the key is to be the "5" key on the numeric keypad
<code>pad6</code>	the key is to be the "6" key on the numeric keypad
<code>pad7</code>	the key is to be the "7" key on the numeric keypad
<code>pad8</code>	the key is to be the "8" key on the numeric keypad
<code>pad9</code>	the key is to be the "9" key on the numeric keypad
<code>paddot</code>	the key is to be the "." key on the numeric keypad
<code>padenter</code>	the key is to be the "Enter" key on the numeric keypad

padplus	the key is to be the "+" key on the numeric keypad
padminus	the key is to be the "-" key on the numeric keypad
padstar	the key is to be the "*" key on the numeric keypad
padslash	the key is to be the "/" key on the numeric keypad
padequal	the key is to be the "=" key on the numeric keypad
padsep	the key is to be the ";" (separator) key on the numeric keypad
lf (<i>n</i>)	the key is to be the left-hand function key <i>n</i>
rf (<i>n</i>)	the key is to be the right-hand function key <i>n</i>
tf (<i>n</i>)	the key is to be the top function key <i>n</i>
bf (<i>n</i>)	the key is to be the "bottom" function key <i>n</i>
nop	the key is to do nothing
error	this code indicates an internal error; to be used only for keystation 126, and must be used there
idle	this code indicates that the keyboard is idle (that is, has no keys down); to be used only for all entries other than the num1 and up table entries for keystation 127, and must be used there
oops	this key exists, but its action is not defined; it has the same effect as nop
reset	this code indicates that the keyboard has just been reset; to be used only for the up table entry for keystation 127, and must be used there.
swap <i>number1</i> with <i>number2</i>	exchanges the entries for keystations <i>number1</i> and <i>number2</i> .
key <i>number1</i> same as <i>number2</i>	sets the entries for keystation <i>number1</i> to be the same as those for keystation <i>number2</i> . If the file does not specify entries for keystation <i>number2</i> , the entries currently in the translation table are used; if the file does specify entries for keystation <i>number2</i> , those entries are used.

EXAMPLES **EXAMPLE 1** Example of setting multiple keystations.

The following entry sets keystation 15 to be a "hole" (that is, an entry indicating that there is no keystation 15); sets keystation 30 to do nothing when Alt Graph is down, generate "!" when Shift is down, and generate "1" under all other circumstances; and sets keystation 76 to be the left-hand Control key.

keytables(4)

EXAMPLE 1 Example of setting multiple keystations. *(Continued)*

```
key 15   all hole
key 30   base 1 shift ! caps 1 ctrl 1 altg nop
key 76   all shiftkeys+leftctrl up shiftkeys+leftctrl
```

EXAMPLE 2 Exchange DELETE and BACKSPACE keys

The following entry exchanges the Delete and Back Space keys on the Type 4 keyboard:

```
swap 43 with 66
```

Keystation 43 is normally the Back Space key, and keystation 66 is normally the Delete key.

EXAMPLE 3 Disable CAPS LOCK key

The following entry disables the Caps Lock key on the Type 3 and U.S. Type 4 keyboards:

```
key 119 all nop
```

EXAMPLE 4 Standard translation tables for the U.S. Type 4 keyboard

The following specifies the standard translation tables for the U.S. Type 4 keyboard:

```
key 0    all hole
key 1    all buckybits+systembit up buckybits+systembit
key 2    all hole
key 3    all lf(2)
key 4    all hole
key 5    all tf(1)
key 6    all tf(2)
key 7    all tf(10)
key 8    all tf(3)

NAME	krb5.conf – Kerberos configuration file												
SYNOPSIS	/etc/krb5/krb5.conf												
DESCRIPTION	<p>The <code>krb5.conf</code> file contains Kerberos configuration information, including the locations of KDCs and administration daemons for the Kerberos realms of interest, defaults for the current realm and for Kerberos applications, and mappings of host names onto Kerberos realms. This file must reside on all Kerberos clients.</p> <p>The format of the <code>krb5.conf</code> consists of sections headings in square brackets. Each section may contain zero or more configuration variables (called <i>relations</i>), of the form:</p> <pre>relation= relation-value</pre> <p>or</p> <pre>relation-subsection = { relation= relation-value relation= relation-value }</pre> <p>The <code>krb5.conf</code> file may contain any or all of the following seven sections:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>libdefaults</code></td> <td>Contains default values used by the Kerberos V5 library.</td> </tr> <tr> <td style="vertical-align: top;"><code>appdefaults</code></td> <td>Contains subsections for Kerberos V5 applications, where <i>relation-subsection</i> is the name of an application. Each subsection describes application-specific defaults.</td> </tr> <tr> <td style="vertical-align: top;"><code>realms</code></td> <td>Contains subsections for Kerberos realms, where <i>relation-subsection</i> is the name of a realm. Each subsection contains relations that define the properties for that particular realm.</td> </tr> <tr> <td style="vertical-align: top;"><code>domain_realm</code></td> <td>Contains relations which map domain names and subdomains onto Kerberos realm names. This is used by programs to determine what realm a host should be in, given its fully qualified domain name.</td> </tr> <tr> <td style="vertical-align: top;"><code>logging</code></td> <td>Contains relations which determine how Kerberos programs are to perform logging.</td> </tr> <tr> <td style="vertical-align: top;"><code>capaths</code></td> <td>Contains the authentication paths used with direct (nonhierarchical) cross-realm authentication. Entries in this section are used by the client to determine the intermediate realms which may be used in cross-realm</td> </tr> </table>	<code>libdefaults</code>	Contains default values used by the Kerberos V5 library.	<code>appdefaults</code>	Contains subsections for Kerberos V5 applications, where <i>relation-subsection</i> is the name of an application. Each subsection describes application-specific defaults.	<code>realms</code>	Contains subsections for Kerberos realms, where <i>relation-subsection</i> is the name of a realm. Each subsection contains relations that define the properties for that particular realm.	<code>domain_realm</code>	Contains relations which map domain names and subdomains onto Kerberos realm names. This is used by programs to determine what realm a host should be in, given its fully qualified domain name.	<code>logging</code>	Contains relations which determine how Kerberos programs are to perform logging.	<code>capaths</code>	Contains the authentication paths used with direct (nonhierarchical) cross-realm authentication. Entries in this section are used by the client to determine the intermediate realms which may be used in cross-realm
<code>libdefaults</code>	Contains default values used by the Kerberos V5 library.												
<code>appdefaults</code>	Contains subsections for Kerberos V5 applications, where <i>relation-subsection</i> is the name of an application. Each subsection describes application-specific defaults.												
<code>realms</code>	Contains subsections for Kerberos realms, where <i>relation-subsection</i> is the name of a realm. Each subsection contains relations that define the properties for that particular realm.												
<code>domain_realm</code>	Contains relations which map domain names and subdomains onto Kerberos realm names. This is used by programs to determine what realm a host should be in, given its fully qualified domain name.												
<code>logging</code>	Contains relations which determine how Kerberos programs are to perform logging.												
<code>capaths</code>	Contains the authentication paths used with direct (nonhierarchical) cross-realm authentication. Entries in this section are used by the client to determine the intermediate realms which may be used in cross-realm												

	authentication. It is also used by the end-service when checking the transited field for trusted intermediate realms.
	<code>kdc</code> For a KDC, may contain the location of the <code>kdc.conf</code> file.
[libdefaults]	The <code>[libdefaults]</code> section may contain any of the following relations:
	<code>default_realm</code> Identifies the default Kerberos realm for the client. Set its value to your Kerberos realm.
	<code>default_tgs_etypes</code> Identifies the supported list of session key encryption types that should be returned by the KDC. The list may be delimited with commas or whitespace. The supported encryption types are <code>des-cbc-crc</code> and <code>des-cbc-md5</code> .
	<code>default_tkt_etypes</code> Identifies the supported list of session key encryption types that should be requested by the client. The format is the same as for <code>default_tkt_etypes</code> . The supported encryption types are <code>des-cbc-crc</code> and <code>des-cbc-md5</code> .
	<code>clockskew</code> Sets the maximum allowable amount of clock skew in seconds that the library will tolerate before assuming that a Kerberos message is invalid. The default value is 300 seconds, or five minutes.
[appdefaults]	This section contains subsections for Kerberos V5 applications, where <i>relation-subsection</i> is the name of an application. Each subsection contains relations that define the default behaviors for that application.
	<pre>gkadmin = { help_url = http://localhost:8888/ab2/coll.384.1/SEAM }</pre>
	The following application defaults can be set to <code>true</code> or <code>false</code> :
	<pre>kinit forwardable proxiable renewable max_life = <i>delta_time</i> max_renewable_life = <i>delta_time</i></pre>
	(See <code>kinit(1)</code> for the valid time duration formats you can specify for <i>delta_time</i> .)
	In the following example, <code>kinit</code> will get forwardable tickets by default, and <code>telnet</code> has three default behaviors specified:

```
[appdefaults]
  kinit = {
    forwardable = true
  }

  telnet = {
    forward = true
    encrypt = true
    autologin = true
  }
```

The application defaults specified here are overridden by those specified in the [realms] section.

[realms] This section contains subsections for Kerberos realms, where *relation-subsection* is the name of a realm. Each subsection contains relations that define the properties for that particular realm. The following relations may be specified in each [realms] subsection:

kdc	The name of a host running a KDC for that realm. An optional port number (separated from the hostname by a colon) may be included.
admin_server	Identifies the host where the Kerberos administration daemon (kadmind) is running. Typically, this is the master KDC.
application defaults	Application defaults that are specific to a particular realm can be specified within a [realms] subsection. Realm-specific application defaults override the global defaults specified in the [appdefaults] section.
kpasswd_server	Identifies the host where the Kerberos password-changing server is running. Typically, this is the same as host indicated in the admin_server. If this parameter is omitted, the host in admin_server is used. You can also specify a port number if the server indicated by kpasswd_server runs on a port other than 464 (the default). The format of this parameter is: <i>hostname[:port]</i> .
kpasswd_protocol	Identifies the protocol to be used when communicating with the server indicated by kpasswd_server. By default, this parameter is defined to be RPCSEC_GSS, which is the protocol used by SEAM-based administration servers. To be able to change a principal's password stored on non-SEAM-based Kerberos server, such as Microsoft Active Directory or MIT Kerberos, this value should be SET_CHANGE. This indicates that a non-RPC-based protocol will be used to communicate the password change request to the

server in the `kpasswd_server` entry.

Note that `kpasswd_server` and `kpasswd_protocol` are realm-specific parameters. Most often, you need to specify them only when using a non-SEAM-based Kerberos server. Otherwise, the change request is sent over `RPCSEC_GSS` to the SEAM administration server.

[domain_realm]

This section provides a translation from a domain name or hostname to a Kerberos realm name. The *relation* can be a host name, or a domain name, where domain names are indicated by a period (`.`) prefix. *relation-value* is the Kerberos realm name for that particular host or domain. Host names and domain names should be in lower case.

If no translation entry applies, the host's realm is considered to be the hostname's domain portion converted to upper case. For example, the following [domain_realm] section maps `crash.mit.edu` into the `TEST.ATHENA.MIT.EDU` realm:

```
[domain_realm]
.mit.edu = ATHENA.MIT.EDU
mit.edu = ATHENA.MIT.EDU
crash.mit.edu = TEST.ATHENA.MIT.EDU
.fubar.org = FUBAR.ORG
fubar.org = FUBAR.ORG
```

All other hosts in the `mit.edu` domain will map by default to the `ATHENA.MIT.EDU` realm, and all hosts in the `fubar.org` domain will map by default into the `FUBAR.ORG` realm. Note the entries for the hosts `mit.edu` and `fubar.org`. Without these entries, these hosts would be mapped into the Kerberos realms `EDU` and `ORG`, respectively.

[logging]

This section indicates how Kerberos programs are to perform logging. There are two types of relations for this section: relations to specify how to log and a relation to specify how to rotate kdc log files.

The following relations may be defined to specify how to log. The same relation can be repeated if you want to assign it multiple logging methods.

<code>admin_server</code>	Specifies how to log the Kerberos administration daemon (<code>kadmind</code>). The default is <code>FILE:/var/krb5/kadmin.log</code> .
<code>default</code>	Specifies how to perform logging in the absence of explicit specifications otherwise.
<code>kdc</code>	Specifies how the KDC is to perform its logging. The default is <code>FILE:/var/krb5/kdc.log</code> .

The `admin_server`, `default`, and `kdc` relations may have the following values:

`FILE:filename`

or

<code>FILE=<i>filename</i></code>	This value causes the entity's logging messages to go to the specified file. If the '=' form is used, the file is overwritten. If the ':' form is used, the file is appended to.
<code>STDERR</code>	This value causes the entity's logging messages to go to its standard error stream.
<code>CONSOLE</code>	This value causes the entity's logging messages to go to the console, if the system supports it.
<code>DEVICE=<i>devicename</i></code>	This causes the entity's logging messages to go to the specified device.
<code>SYSLOG [:<i>severity</i> [:<i>facility</i>]]</code>	This causes the entity's logging messages to go to the system log.

The *severity* argument specifies the default severity of system log messages. This may be any of the following severities supported by the `syslog(3C)` call, minus the `LOG_` prefix: `LOG_EMERG`, `LOG_ALERT`, `LOG_CRIT`, `LOG_ERR`, `LOG_WARNING`, `LOG_NOTICE`, `LOG_INFO`, and `LOG_DEBUG`. For example, a value of `CRIT` would specify `LOG_CRIT` severity.

The *facility* argument specifies the facility under which the messages are logged. This may be any of the following facilities supported by the `syslog(3C)` call minus the `LOG_` prefix: `LOG_KERN`, `LOG_USER`, `LOG_MAIL`, `LOG_DAEMON`, `LOG_AUTH`, `LOG_LPR`, `LOG_NEWS`, `LOG_UUCP`, `LOG_CRON`, and `LOG_LOCAL0` through `LOG_LOCAL7`.

If no severity is specified, the default is `ERR`. If no facility is specified, the default is `AUTH`.

The following relation may be defined to specify how to rotate `kdc` log files if the `FILE:` value is being used to log:

`kdc_rotate` A relation subsection that enables `kdc` logging to be rotated to multiple files based on a time interval. This can be used to avoid logging to one file, which may grow too large and bring the KDC to a halt.

The time interval for the rotation is specified by the `period` relation. The number of log files to be rotated is specified by the `versions` relation. Both the `period` and `versions` (described below) should be included in this subsection. And, this subsection applies only if the `kdc` relation has a `FILE:` value.

The following relations may be specified for the `kdc_rotate` relation subsection:

`period=delta_time` Specifies the time interval before a new log file is created. See the `Time Formats` section in `kinit(1)` for the valid time duration formats you can specify for

delta_time. If *period* is not specified or set to "never", no rotation will occur.

Specifying a time interval does not mean that the log files will be rotated at the time interval based on real time. This is because the time interval is checked at each attempt to write a record to the log, or when logging is actually occurring. Therefore, rotation occurs only when logging has actually occurred for the specified time interval.

versions=number Specifies how many previous versions will be saved before the rotation begins. A number will be appended to the log file, starting with 0 and ending with (*number* - 1). For example, if *versions* is set to 2, up to three logging files will be created (*filename*, *filename.0*, and *filename.1*) before the first one is overwritten to begin the rotation.

Notice that if *versions* is not specified or set to 0, only one log file will be created, but it will be overwritten whenever the time interval is met.

In the following example, the logging messages from the Kerberos administration daemon will go to the console. The logging messages from the KDC will be appended to the `/var/krb5/kdc.log`, which will be rotated between twenty-one log files with a specified time interval of a day.

```
[logging]
  admin_server = CONSOLE
  kdc = FILE:/export/logging/kadmin.log
  kdc_rotate = {
    period = 1d
    versions = 20
  }
```

[capaths] In order to perform direct (non-hierarchical) cross-realm authentication, a database is needed to construct the authentication paths between the realms. This section defines that database.

A client will use this section to find the authentication path between its realm and the realm of the server. The server will use this section to verify the authentication path used by the client, by checking the *transited* field of the received ticket.

There is a subsection for each participating realm, and each subsection has relations named for each of the realms. The *relation-value* is an intermediate realm which may participate in the cross-realm authentication. The relations may be repeated if there is more than one intermediate realm. A value of '.' means that the two realms share keys directly, and no intermediate realms should be allowed to participate.

There are n^2 possible entries in this table, but only those entries which will be needed on the client or the server need to be present. The client needs a subsection

named for its local realm, with relations named for all the realms of servers it will need to authenticate with. A server needs a subsection named for each realm of the clients it will serve.

For example, ANL.GOV, PNL.GOV, and NERSC.GOV all wish to use the ES.NET realm as an intermediate realm. ANL has a sub realm of TEST.ANL.GOV, which will authenticate with NERSC.GOV but not PNL.GOV. The [capath] section for ANL.GOV systems would look like this:

```
[capaths]
  ANL.GOV = {
    TEST.ANL.GOV = .
    PNL.GOV = ES.NET
    NERSC.GOV = ES.NET
    ES.NET = .
  }

  TEST.ANL.GOV = {
    ANL.GOV = .
  }

  PNL.GOV = {
    ANL.GOV = ES.NET
  }

  NERSC.GOV = {
    ANL.GOV = ES.NET
  }

  ES.NET = {
    ANL.GOV = .
  }
```

The [capath] section of the configuration file used on NERSC.GOV systems would look like this:

```
[capaths]
  NERSC.GOV = {
    ANL.GOV = ES.NET
    TEST.ANL.GOV = ES.NET
    TEST.ANL.GOV = ANL.GOV
    PNL.GOV = ES.NET
    ES.NET = .
  }

  ANL.GOV = {
    NERSC.GOV = ES.NET
  }

  PNL.GOV = {
    NERSC.GOV = ES.NET
  }

  ES.NET = {
    NERSC.GOV = .
  }
```

krb5.conf(4)

```
}  
  
TEST.ANL.GOV = {  
    NERSC.GOV = ANL.GOV  
    NERSC.GOV = ES.NET  
}
```

In the above examples, the ordering is not important, except when the same relation is used more than once. The client will use this to determine the path. (It is not important to the server, since the transited field is not sorted.)

EXAMPLES

EXAMPLE 1 Sample file

Here is an example of a generic `krb5.conf` file:

```
[libdefaults]  
    ticket_lifetime = 600  
    default_realm = ATHENA.MIT.EDU  
    default_tkt_enctypes = des-cbc-crc  
    default_tgs_enctypes = des-cbc-crc  
  
[realms]  
    ATHENA.MIT.EDU = {  
        kdc = kerberos.mit.edu  
        kdc = kerberos-1.mit.edu  
        kdc = kerberos-2.mit.edu  
        admin_server = kerberos.mit.edu  
        default_domain = mit.edu  
    }  
  
    FUBAR.ORG = {  
        kdc = kerberos.fubar.org  
        kdc = kerberos-1.fubar.org  
        admin_server = kerberos.fubar.org  
    }  
  
[domain_realm]  
    .mit.edu = ATHENA.MIT.EDU  
    mit.edu = ATHENA.MIT.EDU
```

FILES /var/krb5/kdc.log KDC logging file

SEE ALSO kinit(1), syslog(3C), SEAM(5)

NOTES If the `krb5.conf` file is not formatted properly, the `telnet` command will fail. However, the `dtlogin` and `login` commands will still succeed, even if the `krb5.conf` file is specified as required for the commands. If this occurs, the following error message will be displayed:

```
Error initializing krb5: Improper format of
```

krb5.conf(4)

To bypass any other problems that may occur, you should fix the file as soon as possible.

ldapfilter.conf(4)

NAME	ldapfilter.conf – configuration file for LDAP filtering routines										
SYNOPSIS	/etc/opt/SUNWconn/ldap/current/ldapfilter.conf										
DESCRIPTION	<p>The <code>ldapfilter.conf</code> file contains information used by the LDAP filtering routines.</p> <p>Blank lines and lines that begin with a hash character (<code>#</code>) are treated as comments and ignored. The configuration information consists of lines that contain one to five tokens. Tokens are separated by white space, and double quotes can be used to include white space inside a token.</p> <p>The file consists of a sequence of one or more filter sets. A filter set begins with a line containing a single token called a <i>tag</i>.</p> <p>The filter set consists of a sequence of one or more filter lists. The first line in a filter list must contain four or five tokens: the <i>value pattern</i>, the <i>delimiter list</i>, a <i>filter template</i>, a <i>match description</i>, and an optional <i>search scope</i>. The <i>value pattern</i> is a regular expression that is matched against the <i>value</i> passed to the LDAP library call to select the filter list.</p> <p>The <i>delimiter list</i> is a list of the characters (in the form of a single string) that can be used to break the <i>value</i> into distinct words.</p> <p>The <i>filter template</i> is used to construct an LDAP filter (see description below)</p> <p>The <i>match description</i> is returned to the caller along with a filter as a piece of text that can be used to describe the sort of LDAP search that took place. It should correctly compete both of the following phrases: "One <i>match description</i> match was found for..." and "Three <i>match description</i> matches were found for..."</p> <p>The <i>search scope</i> is optional, and should be one of "base", "onelevel", or "subtree". If <i>search scope</i> is not provided, the default is "subtree".</p> <p>The remaining lines of the filter list should contain two or three tokens, a <i>filter template</i>, a <i>match description</i> and an optional <i>search scope</i>.</p> <p>The <i>filter template</i> is similar in concept to a <code>printf(3C)</code> style format string. Everything is taken literally except for the character sequences:</p> <table><tr><td><code>%v</code></td><td>Substitute the entire <i>value</i> string in place of the <code>%v</code>.</td></tr><tr><td><code>%v\$</code></td><td>Substitute the last word in this field.</td></tr><tr><td><code>%vN</code></td><td>Substitute word <i>N</i> in this field (where <i>N</i> is a single digit 1-9). Words are numbered from left to right within the <i>value</i> starting at 1.</td></tr><tr><td><code>%vM-N</code></td><td>Substitute the indicated sequence of words where <i>M</i> and <i>N</i> are both single digits 1-9.</td></tr><tr><td><code>%vN-</code></td><td>Substitute word <i>N</i> through the last word in <i>value</i> where <i>N</i> is again a single digit 1-9.</td></tr></table>	<code>%v</code>	Substitute the entire <i>value</i> string in place of the <code>%v</code> .	<code>%v\$</code>	Substitute the last word in this field.	<code>%vN</code>	Substitute word <i>N</i> in this field (where <i>N</i> is a single digit 1-9). Words are numbered from left to right within the <i>value</i> starting at 1.	<code>%vM-N</code>	Substitute the indicated sequence of words where <i>M</i> and <i>N</i> are both single digits 1-9.	<code>%vN-</code>	Substitute word <i>N</i> through the last word in <i>value</i> where <i>N</i> is again a single digit 1-9.
<code>%v</code>	Substitute the entire <i>value</i> string in place of the <code>%v</code> .										
<code>%v\$</code>	Substitute the last word in this field.										
<code>%vN</code>	Substitute word <i>N</i> in this field (where <i>N</i> is a single digit 1-9). Words are numbered from left to right within the <i>value</i> starting at 1.										
<code>%vM-N</code>	Substitute the indicated sequence of words where <i>M</i> and <i>N</i> are both single digits 1-9.										
<code>%vN-</code>	Substitute word <i>N</i> through the last word in <i>value</i> where <i>N</i> is again a single digit 1-9.										

EXAMPLES

EXAMPLE 1 The following ldap filter configuration file contains two filter sets, `example1` and `example2 onelevel`, each of which contains four filter lists.

```
# ldap filter file
#
example1
"=" " " "%v" "arbitrary filter"
"[0-9][0-9-]*" " " "(telephoneNumber=%v)" "phone number"

"@ " " "(mail=%v)" "email address"

"^.[. _].*" ". _" "(cn=%v1* %v2-)" "first initial"

".*.[. _].$" ". _" "(cn=%v1-*)" "last initial"

"[. _]" ". _" "(|(sn=%v1-)(cn=%v1-))" "exact"
"(|(sn~=%v1-)(cn~=%v1-))" "approximate"

".*" ". " "(|(cn=%v1)(sn=%v1)(uid=%v1))" "exact"
"(|(cn~=%v1)(sn~=%v1))" "approximate"

"example2 onelevel"
"^..$" " " "(|(o=%v)(c=%v)(l=%v)(co=%v))" "exact" "onelevel"
"(|(o~=%v)(c~=%v)(l~=%v)(co~=%v))" "approximate"
"onelevel"

" " " " "(|(o=%v)(l=%v)(co=%v))" "exact" "onelevel"
"(|(o~=%v)(l~=%v)(co~=%v))" "approximate" "onelevel"

"." " " "(associatedDomain=%v)" "exact" "onelevel"

".*" " " "(|(o=%v)(l=%v)(co=%v))" "exact" "onelevel"
"(|(o~=%v)(l~=%v)(co~=%v))" "approximate" "onelevel"
```

ldapsearchprefs.conf(4)

NAME	ldapsearchprefs.conf – configuration file for LDAP search preference routines
SYNOPSIS	<code>/etc/opt/SUNWconn/ldap/current/ldapsearchprefs.conf</code>
DESCRIPTION	<p>The <code>ldapsearchprefs.conf</code> file contains information used by LDAP when searching the directory. Blank lines and lines that start with a hash (<code>#</code>) character are treated as comments and ignored. Non-comment lines contain one or more tokens. Tokens are separated by white space, and double quotes can be used to include white space inside a token.</p> <p>Search preferences are typically used by LDAP-based client programs to specify what a user may search for, which attributes are searched, and which options are available to the user.</p> <p>The first non-comment line specifies the version of the template information and must contain the token <code>Version</code> followed by an integer version number. For example:</p> <pre>Version 1</pre> <p>The current version is <code>1</code>, so the above example is always the correct opening line.</p> <p>The remainder of the file consists of one or more search preference configurations. The first line of a search preference is a human-readable name for the type of object being searched for, for example <code>People</code> or <code>Organizations</code>. This name is stored in the <code>so_objtypeprompt</code> member of the <code>ldap_searchobj</code> structure (see <code>ldap_searchprefs(3LDAP)</code>). For example,</p> <pre>People</pre> <p>specifies a label for a search preference designed to find X.500 entries for people.</p> <p>The next line specifies a list of options for this search object. The only option currently allowed is "internal" which means that this search object should not be presented directly to a user. Options are placed in the <code>so_options</code> member of the <code>ldap_searchobj</code> structure and can be tested using the <code>LDAP_IS_SEARCHOBJ_OPTION_SET()</code> macro. Use "" if no special options are required.</p> <p>The next line specifies a label to use for "Fewer Choices" searches. "Fewer Choices" searches are those where the user's input is fed to the <code>ldap_filter</code> routines to determine an appropriate filter to use. This contrasts with explicitly-constructed LDAP filters, or "More Choices" searches, where the user can explicitly construct an LDAP filter.</p> <p>For example:</p> <pre>"Search For:"</pre> <p>can be used by LDAP client programs to label the field into which the user can type a "Fewer Choices" search.</p> <p>The next line specifies an LDAP filter prefix to append to all "More Choices" searched. This is typically used to limit the types of entries returned to those containing a specific object class. For example:</p>

```
"(&(objectClass=person) "
```

would cause only entries containing the object class *person* to be returned by a search. Note that parentheses may be unbalanced here, since this is a filter prefix, not an entire filter.

The next line is an LDAP filter tag which specifies the set of LDAP filters to be applied for "Fewer Choices" searching. The line

```
"x500-People"
```

would tell the client program to use the set of LDAP filters from the ldap filter configuration file tagged "x500-People".

The next line specifies an LDAP attribute to retrieve to help the user choose when several entries match the search terms specified. For example:

```
"title"
```

specifies that if more than one entry matches the search criteria, the client program should retrieve the `title` attribute that and present that to the user to allow them to select the appropriate entry. The next line specifies a label for the above attribute, for example,

```
"Title:"
```

Note that the values defined so far in the file are defaults, and are intended to be overridden by the specific search options that follow.

The next line specifies the scope of the LDAP search to be performed. Acceptable values are `subtree`, `onelevel`, and `base`.

The next section is a list of "More Choices" search options, terminated by a line containing only the string `END`. For example:

```
"Common Name"   cn    11111   ""   ""
"Surname"       sn    11111   ""   ""
"Business Phone" "telephoneNumber" 11101   ""   ""
END
```

Each line represents one method of searching. In this example, there are three ways of searching - by Common Name, by Surname, and by Business Phone number. The first field is the text which should be displayed to user. The second field is the attribute which will be searched. The third field is a bitmap which specifies which of the match types are permitted for this search type. A "1" value in a given bit position indicates that a particular match type is valid, and a "0" indicates that it is not valid. The fourth and fifth fields are, respectively, the select attribute name and on-screen name for the selected attribute. These values are intended to override the defaults defined above. If no specific values are specified, the client software uses the default values above.

The next section is a list of search match options, terminated by a line containing only the string `END`. Example:

```
"exactly matches" "(%a=%v)"
"approximately matches" "(%a~=%v)"
"starts with" "(%a=%v*)"
"ends with" "(%a=%*v)"
"contains" "(%a=%*%v*)"
```

ldapsearchprefs.conf(4)

END

In this example, there are five ways of refining the search. For each method, there is an LDAP filter suffix which is appended to the ldap filter.

EXAMPLES

EXAMPLE 1 The following example illustrates one possible configuration of search preferences for "people".

```
# Version number
Version 1
# Name for this search object
People
# Label to place before text box user types in
"Search For:"
# Filter prefix to append to all "More Choices" searches
"(&(objectClass=person) "
# Tag to use for "Fewer Choices" searches - from ldapfilter.conf file
"x500-People"
# If a search results in > 1 match, retrieve this attribute to help
# user distinguish between the entries...
multilineDescription
# ...and label it with this string:
"Description"
# Search scope to use when searching
subtree
# Follows a list of "More Choices" search options. Format is:
# Label, attribute, select-bitmap, extra attr display name, extra attr ldap name
# If last two are null, "Fewer Choices" name/attributes used
"Common Name"          cn             11111  ""  ""
"Surname"              sn             11111  ""  ""
"Business Phone"      "telephoneNumber"  11101  ""  ""
"E-Mail Address"      "mail"        11111  ""  ""
"Uniquename"          "uid"         11111  ""  ""
END
# Match types
"exactly matches"      "(%a=%v) "
"approximately matches" "(%a~=%v) "
"starts with"          "(%a=%v*)" "
"ends with"            "(%a=%v*)" "
"contains"             "(%a=%v*)" "
END
```

In this example, the user may search for People. For "fewer choices" searching, the tag for the ldapfilter.conf(4) file is "x500-People".

ldaptemplates.conf(4)

NAME	ldaptemplates.conf – configuration file for LDAP display template routines
SYNOPSIS	<code>/etc/opt/SUNWconn/ldap/current/ldaptemplates.conf</code>
DESCRIPTION	<p>The <code>ldaptemplates.conf</code> file contains information used by the LDAP display routines.</p> <p>Blank lines and lines that start with a hash character (<code>#</code>) are treated as comments and ignored. Non-comment lines contain one or more tokens. Tokens are separated by white space, and double quotes can be used to include white space inside a token.</p> <p>The first non-comment line specifies the version of the template information and must contain the token <code>Version</code> followed by an integer version number. For example,</p> <pre>Version 1</pre> <p>The current version is <code>1</code>, so the above example is always the correct first line.</p> <p>The remainder of the file consists of one or more display templates. The first two lines of the display template each contain a single token that specifies singular and plural names for the template in a user-friendly format. For example,</p> <pre>"Person" "People"</pre> <p>specifies appropriate names for a template designed to display person information.</p> <p>The next line specifies the name of the icon or similar element that is associated with this template. For example,</p> <pre>"person icon"</pre> <p>The next line is a blank-separated list of template options. <code>""</code> can be used if no options are desired. Available options are: <code>addable</code> (it is appropriate to allow entries of this type to be added), <code>modrdn</code> (it is appropriate to offer the <code>modify rdn</code> operation), <code>altview</code> (this template is an alternate view of another template). For example,</p> <pre>"addable" "modrdn"</pre> <p>The next portion of the template is a list of X.500 object classes that is used to determine whether the template should be used to display a given entry. The object class information consists of one or more lines, followed by a terminating line that contains the single token <code>END</code>. Each line contains one or more object class names, all of which must be present in a directory entry. Multiple lines can be used to associate more than one set of object classes with a given template. For example,</p> <pre>emailPerson orgPerson END</pre> <p>means that the template is appropriate for display of <code>emailPerson</code> entries or <code>orgPerson</code> entries.</p> <p>The next line after the object class list is the name of the attribute to authenticate as to make changes (use <code>""</code> if it is appropriate to authenticate as the entry itself). For example,</p>

```
"owner"
```

The next line is the default attribute to use when naming a new entry, for example,

```
"cn"
```

The next line is the distinguished name of the default location under which new entries are created. For example,

```
"o=XYZ, c=US"
```

The next section is a list of rules used to assign default values to new entries. The list should be terminated with a line that contains the single token `END`. Each line in this section should either begin with the token `constant` and be followed by the name of the attribute and a constant value to assign, or the line should begin with `addersdn` followed by the name of an attribute whose value will be the DN of the person who has authenticated to add the entry. For example,

```
constant    associatedDomain    XYZ.us
addersdn    seeAlso
END
```

The last portion of the template is a list of items to display. It consists of one or more lines, followed by a terminating line that contains the single token `END`. Each line is must begin with the token `samerow` or the token `item`

It is assumed that each item appears on a row by itself unless it was preceded by a `samerow` line (in which case it should be displayed on the same line as the previous item, if possible). Lines that begin with `samerow` should not have any other tokens on them.

Lines that begin with `item` must have at least three more tokens on them: an item type, a label, and an attribute name. Any extra tokens are taken as extra arguments.

The item type token must be one of the following strings:

<code>cis</code>	case-ignore string attributes
<code>mls</code>	multiline string attributes
<code>mail</code>	RFC-822 conformant mail address attributes
<code>dn</code>	distinguished name pointer attributes
<code>bool</code>	Boolean attributes
<code>jpeg</code>	JPEG photo attributes
<code>jpegbtn</code>	a button that will retrieve and show a JPEG photo attribute
<code>fax</code>	FAX T.4 format image attributes
<code>faxbtn</code>	a button that will retrieve and show a FAX photo attribute
<code>audiobtn</code>	audio attributes

ldaptemplates.conf(4)

```
time          UTC time attributes
date          UTC time attributes where only the date portion should be shown
url           labeled Uniform Resource Locator attributes
searchact     define an action that will do a directory search for other entries
linkact       define an action which is a link to another display template
protected     for an encrypted attribute, with values displayed as asterisks
```

An example of an item line for the drink attribute (displayed with label "Work Phone"):

```
item cis      "Work Phone"    telephoneNumber
```

EXAMPLES

EXAMPLE 1 The following template configuration file contains a templates for display of people entries.

```
#
# LDAP display templates
#
# Version must be 1 for now
#
Version 1
#
# Person template
"Person"
"People"

# name of the icon that is associated with this template
"person icon"

# blank-separated list of template options (" " for none)
"addable"

#
# objectclass list
person
END

#
# name of attribute to authenticate as (" " means auth as this entry)
""

#
# default attribute name to use when forming RDN of a new entry
#
"cn"

#
# default location when adding new entries (DN; " " means no default)
"o=XYZ, c=US"

#
# rules used to define default values for new entries
END
```

EXAMPLE 1 The following template configuration file contains a templates for display of people entries. (Continued)

```
#
# list of items for display
item jpegbtn "View Photo" jpegPhoto "Next Photo"
item audiobtn "Play Sound" audio
item cis "Also Known As" cn
item cis "Title" title
item mls "Work Address" postalAddress
item cis "Work Phone" telephoneNumber
item cis "Fax Number" facsimileTelephoneNumber
item mls "Home Address" homePostalAddress
item cis "Home Phone" homePhone
item cis "User ID" uid
item mail "E-Mail Address" mail
item cis "Description" description
item dn "See Also" seeAlso
END
```

_POSIX_OPEN_MAX	16	/* max # of files a process can have open */
_POSIX_PATH_MAX	255	/* max # of characters in a pathname */

limits(4)

<code>_POSIX_PIPE_BUF</code>	512	<code>/* max # of bytes atomic in write to a pipe */</code>
------------------------------	-----	-----------------------------------------------------------------

SEE ALSO standards(5)

llc2(4)

NAME	llc2 – LLC2 Configuration file
SYNOPSIS	/etc/llc2/default/llc2.*
DESCRIPTION	<p>The <i>llc2</i> files contain information needed by LLC2 to establish the appropriate links to the underlying MAC layer drivers as well as the parameters necessary to configure the LLC (Logical Link Control) Class II Station Component structures for that link.</p> <p>The comments are made up of one or more lines starting with the "#" character in column 1.</p> <p>The main section consists of keyword/value pairs of the form <i>keyword=value</i>, used to initialize the particular adapter.</p> <p>A sample of the <i>llc2</i> is presented below:</p> <pre>devicename=/dev/dnet deviceinstance=1 llc2_on=1 # LLC2: On/Off on this device deviceloopback=1 timeinterval=0 # LLC2: Timer Multiplier acktimer=2 # LLC2: Ack Timer rsptimer=2 # LLC2: Response Timer polltimer=4 # LLC2: Poll Timer rejecttimer=6 # LLC2: Reject Timer rembusytimer=8 # LLC2: Remote Busy Timer inacttimer=30 # LLC2: Inactivity Timer maxretry=6 # LLC2: Maximum Retry Value xmitwindowsz=14 # LLC2: Transmit Window Size rcvwindowsz=14 # LLC2: Receive Window Size</pre>
MAC specific Parameters	<p>The <i>llc2.ppa</i> file contains 4 parameters directly related to the underlying MAC-level driver. These are the name of the physical device, the instance of the device, whether LLC2 can be used with this device, and whether the device is capable of looping back data addressed to the node's unique MAC address, broadcast address, or multicast addresses.</p> <p>Setting the <i>llc2_on</i> parameter to 1 means that LLC2 can be used with this device; setting it to 0 means otherwise. Setting the <i>loopback</i> parameter to 1 means that the LLC2 module will loop back data addressed to this node's unique MAC address or to a broadcast/multicast address.</p> <p>The most likely use is for a media that cannot receive its own transmissions (for example, ethernet) or when the MAC-level driver intentionally does not loop back data addressed to the local node under the assumption that the upper layers have already done so.</p>
Host-Based LLC2 Parameters	<p>The LLC2 contains ten parameters in the configuration file (<i>/etc/llc2/default/llc2.ppa</i>) that apply to configurations using the Host-Based LLC2 component for connection-oriented operation over an Ethernet, Token Ring, or FDDI media.</p>

The ten parameters break down into the following four groups:

- Six parameters deal with timer settings for managing the flow of LLC elements of procedure (PDUs) on a data link connection.
- One parameter is the multiplier that is used to determine the period of the interval timer for the station. A value of 1 means that each tick count represents 100 milliseconds; 5 means each tick count is 500 milliseconds. Should the parameter be omitted, the default value is 5, except for Token Ring links which use a default of 1.
- One parameter indicates how many times an operation should be retried on a data link connection.
- Two parameters are for controlling the number of unacknowledged I PDUs to send or receive on a data link connection.

Additional information on these parameters can be found in ISO 8802-2:1989, Section 7.8.

The following table of Logical Link Control Parameters provides the LLC configuration parameter names, default values, and ranges.

Parameter	Description	Default	Range
timeinterval	The timer ticks in 100 ms intervals. This parameter is used to scale the following 5 timer parameters.	5, except TPR - 1	0 - 10
acktimer	The connection acknowledgment timer length in (100 * timeinterval) ms.	2	> 0
rsptimer	The response acknowledgment timer length in (100 * timeinterval) ms.	2	> 0
polltimer	The connection poll timer length in (100 * timeinterval) ms.	4	> 0
rejecttimer	The connection reject timer length in (100 * timeinterval) ms.	6	> 0
rembusytimer	The connection remote busy timer length in (100 * timeinterval) ms.	8	> 0

llc2(4)

Parameter	Description	Default	Range
<code>inacttimer</code>	The connection inactivity timer length in (100 * <code>timeinterval</code>) ms.	30	> 0
<code>maxretry</code>	The maximum number of retries of an action on a connection.	6	0 - 100
<code>xmitwindow</code>	The maximum number of unacknowledged I-format protocol data units that can be transmitted on a connection before awaiting an acknowledgment.	14	0 - 127
<code>rcvwindow</code>	The maximum number of unacknowledged I-format protocol data units that can be received on a connection before an acknowledgment is sent.	14	0 - 127

Default values are set when the following conditions are true:

- The parameter is not set by the user.
- The user requests a default `/etc/llc2/default/llc2.instance` file, where *instance* is the sequence number, starting with 0, of the adapter as detected by `ifconfig(1M)`. For example, if there are 3 adapters on the machine, the default configuration files will be named in order as `/etc/llc2/default/llc2.0`, `/etc/llc2/default/llc2.1`, and `/etc/llc2/default/llc2.2`.
- The user codes a value of 0 for a parameter.

Timer Parameter Descriptions

`acktimer` The `acktimer` parameter is used to manage the following sample sequences:

1. Attempting to establish, reset, or disconnect a connection.

```
SABME      start acknowledgment timer
or  ----->
DISC
```

The acknowledgment timer expires before the receipt of a response.

```
SABME      start acknowledgment timer
or  ----->
DISC
```

```
stop acknowledgment timer
<----- UA
```

2. Sending an FRMR in response to a received PDU of dubious distinction:

```

PDU with invalid N(R)
or
I PDU with invalid N(S)
or
<----- PDU of invalid length
or
unexpected UA PDU
or
response PDU with
invalid P/F setting

```

```

start acknowledgment timer
FRMR ----->

```

Acknowledgment timer expires before the receipt of a PDU.

```

start acknowledgment timer
FRMR ----->

stop acknowledgment timer
<----- SABME, FRMR
DISC, or DM

```

3. There is also a special case of the acknowledgment timer, referred to in this implementation as the response acknowledgment timer (*rsptimer*). It is used when sending an I PDU.

```

start response acknowledgement timer
I ----->

```

Response acknowledgment timer expires before the receipt of an acknowledgment.

```

start poll timer
RR ----->

```

polltimer

The *polltimer* parameter is used to manage situations where a Supervisory command PDU (RR, RNR, or REJ) is sent with the P/F bit set. This type of PDU is typically sent when:

- There has been a period of inactivity on a connection in information transfer mode.
- The remote node must be notified of a local busy condition occurring in information transfer mode.

The expiration of the poll timer causes another Supervisory command PDU (which may be of a different type than the first) to be sent with the P/F bit set, provided the retry count has not exceeded the maximum retry value. This timer, then, provides an extended retry mechanism for a connection in information transfer mode.

rejecttimer

The *rejecttimer* parameter controls the frequency with which a REJ PDU is sent to a remote node from which an I PDU with an

unexpected N(S) was received and which has not corrected the situation by sending an I PDU with the expected N(S).

```

<----- I PDU with
                unexpected N(S)
                start reject timer
REJ ----->

```

Reject timer expires before the receipt of an I PDU with an expected N(S).

```

                start reject and poll timer
REJ ----->
                stop reject and poll timer
<----- I PDU with
                expected N(S)

```

rembusytimer	The <code>rembusytimer</code> parameter is used to determine how long the local node should wait, after the remote node sends an RNR to indicate it is busy, before sending a Supervisory PDU with the P/F bit set to solicit the current state of the remote node. If the remote node indicates that it has cleared its busy condition before the timer expires, the local node stops the remote busy timer.
inacttimer	The <code>inacttimer</code> parameter controls how much time is allowed to elapse on a connection in information transfer mode between the issuing of command PDUs by the local node. If the inactivity timer expires because a command PDU has not been generated in the configured time interval, a Supervisory PDU with the P/F bit set is sent to the remote node to solicit its current state, provided that the connection is in information transfer mode. Each time a command PDU is sent by the local node, the inactivity timer is restarted.

The following rules of thumb should apply for the timer parameters:

- The `acktimer`, `rsptimer`, and `polltimer` parameters should have small relative values to allow for quick recovery from common transient error conditions on a connection.
- The `rejecttimer` and `rembusytimer` parameters should have intermediate relative values to allow the local and remote nodes time to recover without resorting to possibly unnecessary polling cycles.
- The `inacttimer` parameter should be set to a large relative value to provide a safety net in information transfer mode.

You may need to shift the values for the timer parameters to higher values if bridges are included in the network or a user application requires a substantial amount of time to respond to connection establishment requests or handle information flow.

Maximum Retry Parameter Description

The `maxretry` parameter determines the number of times a recovery operation is performed before notifying the user that an error has occurred on a connection. Typical examples of its use include the following:

- When the remote node fails to respond to a SABME sent by the local node to establish or reset the connection, the SABME is resent each time the acknowledgment timer expires, up to `maxretry` number of times.
- In information transfer mode, if the response acknowledgment timer expires after an I PDU has been sent, an RR with the P/F bit set is sent (and resent each time the poll timer expires) until the remote node responds or `maxretry` number of RRs have been sent.

In general, the `maxretry` value should not need to be large. Since the acknowledgment and poll timers are typically used in recovery operations that involve the `maxretry` parameter, the product of `maxretry` and either `acktimer`, `rsptimer`, or `polltimer` gives a rough estimate of the length of time allotted for the connection to attempt internal error recovery before notifying the user.

Window Size Parameter Descriptions

`rcvwindow`sz The `rcvwindow`sz parameter is used to set the receive window size for I PDUs received locally on a connection. This value should agree with the transmit window size set for the connection at the remote node. If the local `rcvwindow`sz is greater than the remote transmit window size, I PDUs sent by the remote node are not acknowledged quickly. If the local `rcvwindow`sz is less than the remote transmit window size, there is a greater risk of the local node generating FRMR PDUs, requiring intervention by the user application when transient errors on the connection require the remote node to retransmit an I PDU. REJ PDUs are recovered internally.

`xmitwindow`sz The `xmitwindow`sz parameter sets the local transmit window size for a connection. It denotes the number of unacknowledged I PDUs that the local node may have outstanding. The configured value should match the receive window size for the connection at the remote node, based on the same reasoning as for the `rcvwindow`sz parameter.

In many cases, the values assigned to `rcvwindow`sz and `xmitwindow`sz for adapters on a server node will depend on the transmit and receive window sizes specified for another LLC implementation on a client node. In cases where this LLC implementation is resident in both nodes, larger values for these parameters are useful in environments where much of the activity on a connection consists of file transfer operations. Smaller values are warranted if analysis of LLC2 connection component statistics reveals that connections are entering local or remote busy state frequently.

logindevperm(4)

NAME	logindevperm, fbtabs – login-based device permissions
SYNOPSIS	/etc/logindevperm
DESCRIPTION	<p>The /etc/logindevperm file contains information that is used by login(1) and ttymon(1M) to change the owner, group, and permissions of devices upon logging into or out of a console device. By default, this file contains lines for the keyboard, mouse, audio, and frame buffer devices.</p> <p>The owner of the devices listed in /etc/logindevperm is set to the owner of the console by login(1). The group of the devices is set to the owner's group specified in /etc/passwd. The permissions are set as specified in /etc/logindevperm.</p> <p>Fields are separated by TAB and/or SPACE characters. Blank lines and comments can appear anywhere in the file; comments start with a hashmark, '#', and continue to the end of the line.</p> <p>The first field specifies the name of a console device (for example, /dev/console). The second field specifies the permissions to which the devices in the <i>device_list</i> field (third field) will be set. A <i>device_list</i> is a colon-separated list of device names. A device entry that is a directory name and ends with "/*" specifies all entries in the directory (except "." and ".."). For example, "/dev/fbs/*" specifies all frame buffer devices.</p> <p>Once the devices are owned by the user, their permissions and ownership can be changed using chmod(1) and chown(1), as with any other user-owned file.</p> <p>Upon logout the owner and group of these devices will be reset by ttymon(1M) to owner root and root's group as specified in /etc/passwd (typically other). The permissions are set as specified in the /etc/logindevperm file.</p>
FILES	/etc/passwd File that contains user group information.
SEE ALSO	chmod(1), chown(1), login(1), ttymon(1M), passwd(4)
NOTES	/etc/logindevperm provides a superset of the functionality provided by /etc/fbtabs in SunOS 4.x releases.

NAME	loginlog – log of failed login attempts
DESCRIPTION	<p>After five unsuccessful login attempts, all the attempts are logged in the file <code>/var/adm/loginlog</code>. This file contains one record for each failed attempt. Each record contains the login name, tty specification, and time.</p> <p>This is an ASCII file. Each field within each entry is separated from the next by a colon. Each entry is separated from the next by a new-line.</p> <p>By default, <code>loginlog</code> does not exist, so no logging is done. To enable logging, the log file must be created with read and write permission for owner only. Owner must be <code>root</code> and group must be <code>sys</code>.</p>
FILES	<code>/var/adm/loginlog</code>
SEE ALSO	<code>login(1)</code> , <code>passwd(1)</code>

lutab(4)

NAME	lutab – list of boot environments
SYNOPSIS	/etc/lutab
DESCRIPTION	<p>The file <code>/etc/lutab</code> is a list of the boot environments (BEs) configured on a system. There are two entries for each BE. These entries have the following form:</p> <pre>BE_id:BE_name:completion_flag:0 BE_id:root_slice:root_device:1</pre> <p>The fields in the <code>lutab</code> entries are described as follows:</p> <p><i>BE_id</i> A unique, internally generated id for a BE.</p> <p><i>BE_name</i> The user-assigned name of a BE.</p> <p><i>completion_flag</i> Indicates whether the BE is complete (C) or incomplete (NC). A complete BE is one that is not involved in any copy or upgrade operation. A BE can be activated or compared only when it is complete.</p> <p>0 Indicates first of two lines.</p> <p><i>BE_id</i> As described above.</p> <p><i>root_slice</i> Designation of the root slice.</p> <p><i>root_device</i> Device on which the root slice is mounted.</p> <p>1 Indicates second of two lines.</p> <p>The <code>lutab</code> file must not be edited by hand. Any user modification to this file will result in the incorrect operation of live upgrade.</p>
SEE ALSO	<code>lu(1M)</code> , <code>luactivate(1M)</code> , <code>lucreate(1M)</code> , <code>lucurr(1M)</code> , <code>lufslist(1M)</code> , <code>lustatus(1M)</code> , <code>luupgrade(1M)</code> , <code>attributes(5)</code> , <code>live_upgrade(5)</code>
WARNINGS	The <code>lutab</code> file is not a public interface. The format and contents of <code>lutab</code> are subject to change. Use <code>lufslist(1M)</code> and <code>lustatus(1M)</code> to obtain information about BEs.

NAME	magic – file command’s magic number file
SYNOPSIS	<code>/etc/magic</code>
DESCRIPTION	<p>The <code>file(1)</code> command identifies the type of a file using, among other tests, a test for whether the file begins with a certain <i>magic number</i>. The <code>/etc/magic</code> file specifies what magic numbers are to be tested for, what message to print if a particular magic number is found, and additional information to extract from the file.</p> <p>Each line of the file specifies a test to perform. A test compares the data starting at a particular offset in the file with a 1-byte, 2-byte, or 4-byte numeric value or a string. If the test succeeds, a message is printed. The line consists of the following fields (separated by tabs):</p> <p><i>offset type value message</i></p> <p><i>offset</i> A number specifying the offset, in bytes, into the file of the data which is to be tested.</p> <p><i>type</i> The type of the data to be tested. The possible values are:</p> <p style="padding-left: 20px;"><i>byte</i> A one-byte value.</p> <p style="padding-left: 20px;"><i>short</i> A two-byte value.</p> <p style="padding-left: 20px;"><i>long</i> A four-byte value.</p> <p style="padding-left: 20px;"><i>string</i> A string of bytes.</p> <p>The types <i>byte</i>, <i>short</i>, and <i>long</i> may optionally be followed by a mask specifier of the form <i>&number</i>. If a mask specifier is given, the value is AND’ed with the <i>number</i> before any comparisons are done. The <i>number</i> is specified in C form. For instance, 13 is decimal, 013 is octal, and 0x13 is hexadecimal.</p> <p><i>value</i> The value to be compared with the value from the file. If the type is numeric, this value is specified in C form. If it is a string, it is specified as a C string with the usual escapes permitted (for instance, <code>\n</code> for NEWLINE).</p> <p><i>Numeric values</i> may be preceded by a character indicating the operation to be performed. It may be ‘=’, to specify that the value from the file must equal the specified value, ‘<’, to specify that the value from the file must be less than the specified value, ‘>’, to specify that the value from the file must be greater than the specified value, ‘&’, to specify that all the bits in the specified value must be set in the value from the file, ‘^’, to specify that at least one of the bits in the specified value must not be set in the value from the file, or <i>x</i> to specify that any value will match. If the character is omitted, it is assumed to be ‘=’.</p>

magic(4)

For string values, the byte string from the file must match the specified byte string. The byte string from the file which is matched is the same length as the specified byte string.

message

The message to be printed if the comparison succeeds. If the string contains a `printf(3C)` format specification, the value from the file (with any specified masking performed) is printed using the message as the format string.

Some file formats contain additional information which is to be printed along with the file type. A line which begins with the character '`>`' indicates additional tests and messages to be printed. If the test on the line preceding the first line with a '`>`' succeeds, the tests specified in all the subsequent lines beginning with '`>`' are performed, and the messages printed if the tests succeed. The next line which does not begin with a '`>`' terminates this.

FILES `/etc/magic`

SEE ALSO `file(1)`, `file(1B)`, `printf(3C)`

BUGS There should be more than one level of subtests, with the level indicated by the number of '`>`' at the beginning of the line.

NAME	mddb.cf – metadvice state database replica locations
SYNOPSIS	<code>/etc/lvm/mddb.cf</code>
DESCRIPTION	<p>The <code>/etc/lvm/mddb.cf</code> file is created when the <code>metadb(1M)</code> <code>metadb</code> command is invoked. You should never directly edit this file.</p> <p>The file <code>/etc/lvn/mddb.cf</code> is used by the <code>metainit(1M)</code> command to find the locations of the metadvice state databases replicas. The <code>metadb</code> command creates the file and updates it each time it is run. Similar information is entered in the <code>/etc/system</code> file.</p> <p>Each metadvice state database replica has a unique entry in the <code>/etc/lvm/mddb.cf</code> file. Each entry contains the <i>driver</i> and <i>minor</i> unit numbers associated with the block physical device where a replica is stored. Each entry also contains the block number of the master block, which contains a list of all other blocks in the replica.</p> <p>Entries in the <code>/etc/lvm/mddb.cf</code> file are of the form: <i>driver_name minor_t daddr_t checksum</i> where <i>driver_name</i> and <i>minor_t</i> represent the device number of the physical device storing this replica. <i>daddr_t</i> is the disk block address. <i>checksum</i> is used to make certain the entry has not been corrupted. A pound sign (#) introduces a comment.</p>
EXAMPLES	<p>EXAMPLE 1 Sample File</p> <p>The following example shows a <code>mddb.cf</code> file.</p> <pre>#metadvice database location file do not hand edit #driver minor_t daddr_t device id checksum sd 152 16 id1,sd@SSEAGATE_JDD288110MC9LH/a -2613</pre> <p>In the example above, the value for <code>daddr_t</code> indicates that the offset from the start of a given partition is 16 disk blocks from the start of that partition.</p>
FILES	<ul style="list-style-type: none"> ■ <code>/etc/lvm/mddb.cf</code> ■ <code>/etc/system</code>
SEE ALSO	<p><code>metaclear(1M)</code>, <code>metadb(1M)</code>, <code>metadetach(1M)</code>, <code>metahs(1M)</code>, <code>metainit(1M)</code>, <code>metaoffline(1M)</code>, <code>metaonline(1M)</code>, <code>metaparam(1M)</code>, <code>metareplace(1M)</code>, <code>metaroot(1M)</code>, <code>metastat(1M)</code>, <code>metasync(1M)</code>, <code>metattach(1M)</code>, <code>md.tab(4)</code></p> <p><i>Solaris Volume Manager Administration Guide</i></p>

md.tab(4)

NAME	md.tab, md.cf – metadisk utility files
SYNOPSIS	<code>/etc/lvm/md.tab</code> <code>/etc/lvm/md.cf</code>
DESCRIPTION	<p>The file <code>/etc/lvm/md.tab</code> can be used by <code>metainit(1M)</code> and <code>metadb(1M)</code> to configure metadevices, hot spare pools, and metadvice state database replicas in a batch-like mode. Solaris Volume Manager does not store configuration information in the <code>/etc/lvm/md.tab</code> file. The only way information appears in <code>md.tab</code> is through editing it by hand. When using the <code>md.tab</code> file, each metadvice, hot spare pool, or state database replica in the file must have a unique entry. Entries can include the following: simple metadevices (stripes, concatenations, and concatenations of stripes); mirrors, trans metadevices, soft partitions, and RAID5 metadevices; hot spare pools; and state database replicas. Because <code>md.tab</code> contains only entries that you enter in it, do not rely on the file for the current configuration of metadevices, hot spare pools, and replicas on the system at any given time.</p> <p>Tabs, spaces, comments (by using a pound sign, #), and continuation of lines (by using a backslash-newline), are allowed.</p> <p>Typically, you set up metadevices according to information specified on the command line by using the <code>metainit</code> command. Likewise, you set up state database replicas with the <code>metadb</code> command.</p> <p>An alternative to the command line is to use the <code>md.tab</code> file. Metadevices and state database replicas can be specified in the <code>md.tab</code> file in any order, and then activated in a batch-like mode with the <code>metainit</code> and <code>metadb</code> commands.</p> <p>If you edit the <code>md.tab</code> file, you specify one complete configuration entry per line. Metadevices are defined using the same syntax as required by the <code>metainit</code> command. You then run the <code>metainit</code> command with either the <code>-a</code> option, to activate all metadevices in the <code>md.tab</code> file, or with the metadvice name corresponding to a specific configuration entry. State database replicas are defined in the <code>/etc/lvm/md.tab</code> file as follows: <code>mddbnumber options [slice...]</code> Where <code>mddbnumber</code> is the characters <code>mddb</code> followed by a two digit number that identifies the state database replica. <code>slice</code> is a physical slice. For example: <code>mddb05 /dev/dsk/c0t1d0s2</code>. The file <code>/etc/lvm/md.cf</code> is a backup of the configuration used for disaster recovery. Whenever the Volume Manager configuration is changed, this file is automatically updated (except when hot sparing occurs). You should not directly edit this file.</p>
EXAMPLES	<p>EXAMPLE 1 Concatenation</p> <p>All drives in the following examples have the same size of 525 Mbytes.</p> <p>This example shows a metadvice, <code>/dev/md/dsk/d7</code>, consisting of a concatenation of four disks.</p> <pre># # (concatenation of four disks)</pre>

EXAMPLE 1 Concatenation (Continued)

```
#
d7 4 1 c0t1d0s0 1 c0t2d0s0 1 c0t3d0s0 1 c0t4d0s0
```

The number 4 indicates there are four individual stripes in the concatenation. Each stripe is made of one slice, hence the number 1 appears in front of each slice. Note that the first disk sector in all of the above devices contains a disk label. To preserve the labels on devices `/dev/dsk/c0t2d0s0`, `/dev/dsk/c0t3d0s0`, and `/dev/dsk/c0t4d0s0`, the metadisk driver must skip at least the first sector of those disks when mapping accesses across the concatenation boundaries. Since skipping only the first sector would create an irregular disk geometry, the entire first cylinder of these disks will be skipped. This allows higher level file system software to optimize block allocations correctly.

EXAMPLE 2 Stripe

This example shows a metadvice, `/dev/md/dsk/d15`, consisting of two slices.

```
#
# (stripe consisting of two disks)
#
d15 1 2 c0t1d0s2 c0t2d0s2 -i 32k
```

The number 1 indicates that one stripe is being created. Because the stripe is made of two slices, the number 2 follows next. The optional `-i` followed by `32k` specifies the interlace size will be 32 Kbytes. If the interlace size were not specified, the stripe would use the default value of 16 Kbytes.

EXAMPLE 3 Concatenation of Stripes

This example shows a metadvice, `/dev/md/dsk/d75`, consisting of a concatenation of two stripes of three disks.

```
#
# (concatenation of two stripes, each consisting of three disks)
#
d75 2 3 c0t1d0s2 c0t2d0s2 c0t3d0s2 -i 16k \
      3 c1t1d0s2 c1t2d0s2 c1t3d0s2 -i 32k
```

On the first line, the `-i` followed by `16k` specifies that the stripe's interlace size is 16 Kbytes. The second set specifies the stripe interlace size will be 32 Kbytes. If the second set did not specify 32 Kbytes, the set would use default interlace value of 16 Kbytes. The blocks of each set of three disks are interlaced across three disks.

EXAMPLE 4 Mirroring

This example shows a three-way mirror, `/dev/md/dsk/d50`, consisting of three submirrors. This mirror does not contain any existing data.

EXAMPLE 4 Mirroring (Continued)

```
#
# (mirror)
#
d50 -m d51
d51 1 1 c0t1d0s2
d52 1 1 c0t2d0s2
d53 1 1 c0t3d0s2
```

In this example, a one-way mirror is first defined using the `-m` option. The one-way mirror consists of submirror `d51`. The other two submirrors, `d52` and `d53`, are attached later using the `metattach` command. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors. The order in which mirrors appear in the `/etc/lvm/md.tab` file is unimportant.

EXAMPLE 5 Logging (trans)

This example shows a `trans` metadvice, `/dev/md/dsk/d1`, with mirrors for the master and logging devices. This `trans` does not contain any existing data.

```
#
# (trans)
#
d1 -t d10 d20
d10 -m d11
d11 1 1 c0t1d0s2
d12 1 1 c0t2d0s2
d20 -m d21
d21 1 1 c1t1d0s2
d22 1 1 c1t2d0s2
```

In this example, the two mirrors, `d10` and `d20`, are defined using the `-m` option. `d10` is defined as the master device and `d20` is defined as the logging device for the `trans`, `d1`, by using the `-t` option. The order in which mirrors or `trans` appear in the `/etc/lvm/md.tab` file is unimportant. The submirrors `d12` and `d22` are attached later (using the `metattach` command) to the `d10` and `d20` mirrors.

EXAMPLE 6 RAID5

This example shows a RAID5 metadvice, `d80`, consisting of three slices:

```
#
# (RAID devices)
#
d80 -r c0t1d0s1 c1t0d0s1 c2t0d0s1 -i 20k
```

In this example, a RAID5 metadvice is defined using the `-r` option with an interlace size of 20 Kbytes. The data and parity segments will be striped across the slices, `c0t1d0s1`, `c1t0d0s1`, and `c2t0d0s1`.

EXAMPLE 7 Soft Partition

This example shows a soft partition, `d85`, that reformats an entire 9 GB disk. Slice 0 occupies all of the disk except for the few Mbytes taken by slice 7, which is space reserved for a state database replica. (Slice 7 will be a minimum of 2Mbytes, but could be larger, depending on the disk geometry.) `d85` sits on `c3t4d0s0`.

```
#
# (Soft Partitions)
d85 -p -e c3t4d0 9g
```

In this example, creating the soft partition and required space for the state database replica occupies all 9 GB of disk `c3t4d0`.

EXAMPLE 8 Soft Partition

This example shows the command used to re-create a soft partition with two extents, the first one starting at offset 20483 and extending for 20480 blocks and the second extent starting at 135398 and extending for 20480 blocks:

```
#
# (Soft Partitions)
#
d1 -p c0t3d0s0 -o 20483 -b 20480 -o 135398 -b 20480
```

EXAMPLE 9 Hot Spare

This example shows a three-way mirror, `/dev/md/dsk/d10`, consisting of three submirrors and three hot spare pools.

```
#
# (mirror and hot spare)
#
d10 -m d20
d20 1 1 c1t0d0s2 -h hsp001
d30 1 1 c2t0d0s2 -h hsp002
d40 1 1 c3t0d0s2 -h hsp003
hsp001 c2t2d0s2 c3t2d0s2 c1t2d0s2
hsp002 c3t2d0s2 c1t2d0s2 c2t2d0s2
hsp003 c1t2d0s2 c2t2d0s2 c3t2d0s2
```

In this example, a one-way mirror is first defined using the `-m` option. The submirrors are attached later using the `metattach(1M)` command. The hot spare pools to be used are tied to the submirrors with the `-h` option. In this example, there are three disks used as hot spares, defined in three separate hot spare pools. The hot spare pools are given the names `hsp001`, `hsp002`, and `hsp003`. Setting up three hot spare pools rather than assigning just one hot spare with each component helps to maximize the use of hardware. This configuration enables the user to specify that the most desirable hot spare be selected first, and improves availability by having more hot spares available. At the end of the entry, the hot spares to be used are defined. Note that, when using the `md.tab` file, to associate hot spares with metadevices, the hot spare pool does not have to exist prior to the association. Volume Manager takes care of the

EXAMPLE 9 Hot Spare (Continued)

order in which metadevices and hot spares are created when using the `md.tab` file.

EXAMPLE 10 State Database Replicas

This example shows how to set up an initial state database and three replicas on a server that has three disks.

```
#
# (state database and replicas)
#
mddb01 -c 3 c0t1d0s0 c0t2d0s0 c0t3d0s0
```

In this example, three state database replicas are stored on each of the three slices. Once the above entry is made in the `/etc/lvm/md.tab` file, the `metadb` command must be run with both the `-a` and `-f` options. For example, typing the following command creates one state database replicas on three slices:

```
# metadb -a -f mddb01
```

FILES

- `/etc/lvm/md.tab`
- `/etc/lvm/md.cf`

Solaris Volume Manager Administration Guide

LIMITATIONS

Recursive mirroring is not allowed; that is, a mirror cannot appear in the definition of another mirror.

Recursive logging is not allowed; that is, a trans metadvice cannot appear in the definition of another metadvice.

Stripes and RAID5 metadevices must contains slices or soft partitions only.

Mirroring of RAID5 metadevices is not allowed.

Soft partitions can be built directly on slices or can be the top level (accessible by applications directly), but cannot be in the middle, with other metadevices above and below them.

NAME	mech, qop – mechanism and QOP files														
SYNOPSIS	<code>/etc/gss/mech</code> <code>/etc/gss/qop</code>														
DESCRIPTION	<p>The <code>/etc/gss/mech</code> and <code>/etc/gss/qop</code> files contain tables showing installed security mechanisms and the Quality of Protection (QOP) associated with them, respectively. As security mechanisms are installed on the system, entries are added to these two files. Contents of these files may be accessed either manually (for example, with <code>cat(1)</code> or <code>more(1)</code>) or programmatically (with either <code>rpc_gss_get_mechanisms(3NSL)</code> or <code>rpc_gss_get_mech_info(3NSL)</code>).</p> <p>The <code>/etc/gss/mech</code> file contains four fields:</p> <table border="0"> <tr> <td><i>mechanism name</i></td> <td>ASCII string representing the mechanism.</td> </tr> <tr> <td><i>object identifier</i></td> <td>RPC OID for this mechanism.</td> </tr> <tr> <td><i>shared library</i></td> <td>Shared library which implements the services provided by this mechanism.</td> </tr> <tr> <td><i>kernel module</i></td> <td>Kernel module which implements the services provided by this mechanism.</td> </tr> </table> <p>The <code>/etc/gss/qop</code> file contains three fields:</p> <table border="0"> <tr> <td><i>QOP string</i></td> <td>Name, in ASCII, of this Quality of Protection.</td> </tr> <tr> <td><i>QOP value</i></td> <td>Numeric value by which RPC identifies this QOP.</td> </tr> <tr> <td><i>mechanism name</i></td> <td>ASCII string representing the mechanism with which this QOP is associated.</td> </tr> </table>	<i>mechanism name</i>	ASCII string representing the mechanism.	<i>object identifier</i>	RPC OID for this mechanism.	<i>shared library</i>	Shared library which implements the services provided by this mechanism.	<i>kernel module</i>	Kernel module which implements the services provided by this mechanism.	<i>QOP string</i>	Name, in ASCII, of this Quality of Protection.	<i>QOP value</i>	Numeric value by which RPC identifies this QOP.	<i>mechanism name</i>	ASCII string representing the mechanism with which this QOP is associated.
<i>mechanism name</i>	ASCII string representing the mechanism.														
<i>object identifier</i>	RPC OID for this mechanism.														
<i>shared library</i>	Shared library which implements the services provided by this mechanism.														
<i>kernel module</i>	Kernel module which implements the services provided by this mechanism.														
<i>QOP string</i>	Name, in ASCII, of this Quality of Protection.														
<i>QOP value</i>	Numeric value by which RPC identifies this QOP.														
<i>mechanism name</i>	ASCII string representing the mechanism with which this QOP is associated.														
EXAMPLES	<p>EXAMPLE 1 A Typical Entry in <code>/etc/gss/mech</code></p> <p>This is a typical entry in a <code>/etc/gss/mech</code> file:</p> <pre>kerberosv5 1.2.840.113554.1.2.2 mech_krb5.so kmech_krb5</pre> <p>EXAMPLE 2 A Typical Entry in <code>/etc/gss/qop</code></p> <p>This is a typical entry in a <code>/etc/gss/qop</code> file:</p> <pre>GSS_KRB5_CONF_C_QOP_DES 0 kerberosv5</pre>

meddb(4)

NAME	meddb – mediator data file
SYNOPSIS	/etc/lvm/meddb
DESCRIPTION	The file /etc/lvm/meddb is a data file used by <code>rpc.metamedd(1M)</code> to store the mediator data used in 2-string HA configurations.
FILES	/etc/lvm/meddb
SEE ALSO	<code>rpc.metamedd(1M)</code> <i>Sun Cluster 3.0 Collection</i> <i>Solaris Volume Manager Administration Guide</i>

NAME	mipagent.conf – configuration file for Mobile IP mobility agent
SYNOPSIS	<code>/etc/inet/mipagent.conf</code>
DESCRIPTION	<p><code>/etc/inet/mipagent.conf</code> is the configuration file used to initialize the Mobile IP mobility agent described in <code>mipagent(1M)</code>. Three sample configuration files are located in the <code>/etc/inet</code> directory:</p> <pre> /etc/inet/mipagent.conf-sample /etc/inet/mipagent.conf.ha-sample /etc/inet/mipagent.conf.fa-sample </pre> <p>Blank lines are ignored. Lines beginning with the hash character (#) are treated as comments. Sections are denoted by identifiers in brackets. Each section can contain multiple attribute-value pairs. The syntax of an attribute-value pair is an identifier, followed by an equal sign (=), followed by a value.</p> <p>The following sections and attribute-value pairs must be present in <code>/etc/inet/mipagent.conf</code>:</p> <p>[<i>General</i>]</p> <p>This section contains the <code>Version</code> attribute.</p> <p><code>Version</code></p> <p><code>Version</code> is required. For the current release of Mobile IP in Solaris, <code>Version</code> must be 1. Consequently, the default value is 1.</p> <p>[<i>Advertisements interface</i>]</p> <p>This section identifies the interfaces that will serve as Mobile IP mobility agents. <i>interface</i> is the interface name of the advertising interface. Advertising interface name must be specified in the <code>mipagent.conf</code> file, if the interface is already configured. <i>interface</i> attribute has two components, device name and device number, that is, <i>interface</i>=<code>le0</code> indicates device name is <code>le</code> and the device number is 0. The device number part of <i>interface</i> attribute can also have a special symbol * which indicates support of advertisements on interfaces that are configured after the <code>mipagent.conf</code> file, then the advertisement should be done based on that configuration. If <code>le*</code> is present in an <code>Advertisements</code> section, then * represents dynamic interfaces, that is, only those those interfaces that are not already configured in the <code>mipagent.conf</code> file and newly created on the system while <code>mipagent</code> is running. One or more of the following attribute-value pairs may be found in this section:</p> <p><code>AdvLifeTime</code></p> <p>Lifetime (in seconds) advertised in the ICMP router discovery portion of an agent advertisement. See <i>RFC 1256</i>. The default value is 300.</p> <p><code>RegLifeTime</code></p> <p>Lifetime (in seconds) advertised in the mobility extension of an agent advertisement. The default value is 300.</p>

AdvFrequency

The frequency at which agent advertisements are sent and when different entries are aged. This interval must be less than one-third of `AdvLifeTime`. The recommended value for `AdvFrequency` is 1 when `AdvLimitSolicited` is set to `yes`. The default value is 4.

AdvInitCount

The initial number of unsolicited advertisements which are sent when an interface first starts advertising. If this value is set to zero, no unsolicited advertisements are sent out on the *interface*. The default value is 1.

AdvLimitUnsolicited

Determines whether the interface performs limited or unlimited unsolicited agent advertisements. The agent always responds to the agent solicitations in both cases.

`yes` If the value is set to `yes`, then the interface performs `AdvInitCount` number of advertisements when it comes up and then it stops sending unsolicited advertisements.

`no` When the value is set to `no`, the interface performs periodic and unlimited number of unsolicited advertisements. The default value for `AdvLimitUnsolicited` is `no`. When `AdvLimitUnsolicited` is set to the default value, `advInitCount` is also set to its default value.

HomeAgent

Indicates if this agent can act as a home agent. The default value is `yes`.

ForeignAgent

Indicates if this agent can act as a foreign agent. The default value is `yes`.

PrefixFlags

Enables the prefix length extension. The default value is `yes`.

NAIExt

Enables the Network Access Identifier (NAI) extension. The default value is `yes`.

Challenge

Enables the foreign agent challenge extension. The default value is `no`.

ReverseTunnel

Indicates if this interface supports reverse tunneling as specified in *RFC 2344*. `ReverseTunnel` can contain one of the following values:

`no or neither` Indicates this interface does not support reverse tunneling.

`FA` Indicates only the foreign agent supports reverse tunneling.

`HA` Indicates only the home agent supports reverse tunneling.

`yes or both` Indicates that both foreign and home agents support reverse tunneling as specified in *RFC 2344*.

The default value for `ReverseTunnel` is `no`.

`ReverseTunnelRequired`

Indicates if this interface will require reverse tunneling as specified in *RFC 2344*. `ReverseTunnelRequired` can contain one of the following values:

<code>no</code> or <code>neither</code>	Indicates this interface will not require reverse tunneling.
<code>FA</code>	Indicates only the foreign agent will require a reverse tunnel.
<code>HA</code>	Indicates only the home agent will require a reverse tunnel.
<code>yes</code> or <code>both</code>	Indicates that both foreign and home agents will require a reverse tunnel.

The default value for `ReverseTunnelRequired` is `no`.

[`GlobalSecurityParameters`]

This section defines the global security parameters that will be used to authenticate mobile nodes. MN-HA authentication is always enabled. This section may contain one or more the of the following attribute-value pairs:

<code>HA-FAAuth</code>	Enables home agent - foreign agent authentication. The default value is <code>yes</code> .
<code>MN-FAAuth</code>	Enables mobile node - foreign agent authentication. The default value is <code>no</code> .
<code>MaxClockSkew</code>	The maximum allowable difference in <code>clocks</code> , in seconds, that will be tolerated. This is used for replay protection. The default value is <code>300</code> .
<code>KeyDistribution</code>	This attribute defines where keys are found. The default for this version of Solaris Mobile IP software is <code>files</code> .

[`SPI number`]

These sections define multiple Security Parameter Indices (SPIs). One section is required for each security context. These SPI values are used in the `Address` section to define the security used for a particular mobile node or agent. In this section, both the `Key` and `ReplayMethod` attributes must be present.

<code>Key</code>	The hexadecimal representation of the key used for authentication.
<code>ReplayMethod</code>	The replay method. Possible values are <code>timestamps</code> or <code>none</code> .

[`Pool number`]

These sections define address pools for dynamically assigned IP addresses. The `Start` and `Length` attributes both must be present.

<code>Start</code>	The beginning range of the IP address from which to allocate an IP address in dotted quad notation.
<code>Length</code>	The length of the IP address range.

```
[ Address NAI | IPAddr | node-default ]
```

This section defines the security policy used for each host for which an NAI or IP address is specified in the section header. The keyword `node-default` is used to create a single entry that can be used by any mobile node that has the correct SPI and associated keying information. This section specifies the SPI, and in the case of mobile nodes, pool numbers for NAI addresses.

Type Indicates whether the address entry specifies a mobile node or a mobility agent.

SPI The SPI used for this Address.

Pool The Pool used for this NAI address. The Pool keyword may only be present if the Type operand is set to mobile node.

EXAMPLES **EXAMPLE 1** Configuration for Providing Mobility Services on One Interface

The following example shows the configuration file for a mobility agent that provides mobility services on one interface (`le0`). The mobility agent acts both as a home agent as well as a foreign agent on that interface. It includes the prefix length in its advertisements. Its home and foreign agent functions support reverse tunneling, but only the foreign agent requires that a reverse tunnel be configured. The mobility agent provides home agent services to three mobile nodes: `192.168.10.17`, `192.168.10.18`, and the NAI address `user@defaultdomain.com`. The configuration file also indicates that it provides foreign agent service on any PPP interfaces that are dynamically created after the mipagent starts.

With the first mobile node, the agent uses an SPI of 257 (decimal) and a shared secret key that is six bytes long containing alternate bytes that are 0 and 255 (decimal). For the second mobile node, the SPI is 541 (decimal), the key is 10 bytes, and it contains the decimal values 11 through 20 in those bytes. The first mobile node uses no replay protection, and the second uses timestamps. The third mobile node uses NAI and gets its address from Pool 1.

The mobile node will also need to be configured with the same security association that is specified in the home agent's configuration file.

```
# start of file
[ General ]
Version = 1

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmipr

SEE ALSO mipagent(1M), mipagentconfig(1M), attributes(5)

Deering, S., editor. *RFC 1256, ICMP Router Discovery Messages*. Network Working Group. September 1991.

Montenegro, G., editor. *RFC 2344, Reverse Tunneling For Mobile IP*. Network Working Group. May 1998.

Perkins, C., editor. *RFC 2002, IP Mobility Support*. Network Working Group. October 1996.

NOTES The base Mobile IP protocol (*RFC 2002*) does not address the problem of scalable key distribution and treats key distribution as an orthogonal issue. The Solaris Mobile IP software utilizes manually configured keys only, specified in a configuration file.

The * symbol for the interface number determines only those interfaces that are newly configured while mipagent is running. Thus the symbol * in the *interface* excludes any preconfigured interfaces in the system. Interfaces that are already configured in the system need to be specifically mentioned in the mipagent.conf file for advertisement on those interfaces.

The AdvLimitUnsolicited parameter is useful when someone wants to limit unsolicited advertisements on the interface. Limited unsolicited agent advertisement is required for some wireless mobile IP usage.

NAME	<code>mnttab</code> – mounted file system table										
DESCRIPTION	<p>The file <code>/etc/mnttab</code> is really a file system that provides read-only access to the table of mounted file systems for the current host. <code>/etc/mnttab</code> is read by programs using the routines described in <code>getmntent(3C)</code>. Mounting a file system adds an entry to this table. Unmounting removes an entry from this table. Remounting a file system causes the information in the mounted file system table to be updated to reflect any changes caused by the remount. The list is maintained by the kernel in order of mount time. That is, the first mounted file system is first in the list and the most recently mounted file system is last. When mounted on a mount point the file system appears as a regular file containing the current <code>mnttab</code> information.</p> <p>Each entry is a line of fields separated by spaces in the form:</p> <pre><i>special mount_point fstype options time</i></pre> <p>where:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>special</i></td> <td>The name of the resource to be mounted.</td> </tr> <tr> <td><i>mount_point</i></td> <td>The pathname of the directory on which the filesystem is mounted.</td> </tr> <tr> <td><i>fstype</i></td> <td>The file system type of the mounted file system.</td> </tr> <tr> <td><i>options</i></td> <td>The mount options. (See respective mount file system man page in SEE ALSO.)</td> </tr> <tr> <td><i>time</i></td> <td>The time at which the file system was mounted.</td> </tr> </table> <p>Examples of entries for the <i>special</i> field include the pathname of a block-special device, the name of a remote file system in the form of <i>host:pathname</i>, or the name of a <i>swap file</i> (for example, a file made with <code>mkfile(1M)</code>).</p>	<i>special</i>	The name of the resource to be mounted.	<i>mount_point</i>	The pathname of the directory on which the filesystem is mounted.	<i>fstype</i>	The file system type of the mounted file system.	<i>options</i>	The mount options. (See respective mount file system man page in SEE ALSO.)	<i>time</i>	The time at which the file system was mounted.
<i>special</i>	The name of the resource to be mounted.										
<i>mount_point</i>	The pathname of the directory on which the filesystem is mounted.										
<i>fstype</i>	The file system type of the mounted file system.										
<i>options</i>	The mount options. (See respective mount file system man page in SEE ALSO.)										
<i>time</i>	The time at which the file system was mounted.										
IOCTLS	<p>The following <code>ioctl(2)</code> calls are supported:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>MNTIOC_NMNTS</code></td> <td>Returns the count of mounted resources in the current snapshot in the <code>uint32_t</code> pointed to by <i>arg</i>.</td> </tr> <tr> <td><code>MNTIOC_GETDEVLIST</code></td> <td>Returns an array of <code>uint32_t</code>'s that is twice as long as the length returned by <code>MNTIOC_NMNTS</code>. Each pair of numbers is the major and minor device number for the file system at the corresponding line in the current <code>/etc/mnttab</code> snapshot. <i>arg</i> points to the memory buffer to receive the device number information.</td> </tr> <tr> <td><code>MNTIOC_SETTAG</code></td> <td>Sets a tag word into the options list for a mounted file system. A tag is a notation that will appear in the options string of a mounted file system but it is not recognized or interpreted by the file system code. <i>arg</i> points to a filled in <code>mnttagdesc</code> structure, as shown in the following example:</td> </tr> </table>	<code>MNTIOC_NMNTS</code>	Returns the count of mounted resources in the current snapshot in the <code>uint32_t</code> pointed to by <i>arg</i> .	<code>MNTIOC_GETDEVLIST</code>	Returns an array of <code>uint32_t</code> 's that is twice as long as the length returned by <code>MNTIOC_NMNTS</code> . Each pair of numbers is the major and minor device number for the file system at the corresponding line in the current <code>/etc/mnttab</code> snapshot. <i>arg</i> points to the memory buffer to receive the device number information.	<code>MNTIOC_SETTAG</code>	Sets a tag word into the options list for a mounted file system. A tag is a notation that will appear in the options string of a mounted file system but it is not recognized or interpreted by the file system code. <i>arg</i> points to a filled in <code>mnttagdesc</code> structure, as shown in the following example:				
<code>MNTIOC_NMNTS</code>	Returns the count of mounted resources in the current snapshot in the <code>uint32_t</code> pointed to by <i>arg</i> .										
<code>MNTIOC_GETDEVLIST</code>	Returns an array of <code>uint32_t</code> 's that is twice as long as the length returned by <code>MNTIOC_NMNTS</code> . Each pair of numbers is the major and minor device number for the file system at the corresponding line in the current <code>/etc/mnttab</code> snapshot. <i>arg</i> points to the memory buffer to receive the device number information.										
<code>MNTIOC_SETTAG</code>	Sets a tag word into the options list for a mounted file system. A tag is a notation that will appear in the options string of a mounted file system but it is not recognized or interpreted by the file system code. <i>arg</i> points to a filled in <code>mnttagdesc</code> structure, as shown in the following example:										

mnttab(4)

		<pre> uint_t mtd_major; /* major number for mounted fs */ uint_t mtd_minor; /* minor number for mounted fs */ char *mtd_mntpt; /* mount point of file system */ char *mtd_tag; /* tag to set/clear */ </pre> <p>If the tag already exists then it is marked as set but not re-added. Tags can be at most MAX_MNTOPT_TAG long.</p>
	MNTIOC_CLRTAG	Marks a tag in the options list for a mounted file system as not set. <i>arg</i> points to the same structure as MNTIOC_SETTAG, which identifies the file system and tag to be cleared.
ERRORS	EFAULT	The <i>arg</i> pointer in an MNTIOC_ioctl call pointed to an inaccessible memory location or a character pointer in a mnttagdesc structure pointed to an inaccessible memory location.
	EINVAL	The tag specified in a MNTIOC_SETTAG call already exists as a file system option, or the tag specified in a MNTIOC_CLRTAG call does not exist.
	ENAMETOOLONG	The tag specified in a MNTIOC_SETTAG call is too long or the tag would make the total length of the option string for the mounted file system too long.
WARNINGS		<p>The mnttab file system provides the previously undocumented <i>dev=xxx</i> option in the option string for each mounted file system. This is provided for legacy applications that might have been using the <i>dev=information</i> option.</p> <p>Using <i>dev=option</i> in applications is strongly discouraged. The device number string represents a 32-bit quantity and might not contain correct information in 64-bit environments.</p> <p>Applications requiring device number information for mounted file systems should use the <i>getextmntent(3C)</i> interface, which functions properly in either 32- or 64-bit environments.</p>
FILES	/etc/mnttab	Usual mount point for mnttab file system
	/usr/include/sys/mntio.h	Header file that contains IOCTL definitions
SEE ALSO		<i>mkfile(1M)</i> , <i>mount_cachefs(1M)</i> , <i>mount_hsf(1M)</i> , <i>mount_nfs(1M)</i> , <i>mount_pcfs(1M)</i> , <i>mount_ufs(1M)</i> , <i>mount(1M)</i> , <i>ioctl(2)</i> , <i>read(2)</i> , <i>poll(2)</i> , <i>stat(2)</i> , <i>getmntent(3C)</i>
NOTES		The snapshot of the mnttab information is taken any time a <i>read(2)</i> is performed at offset 0 (the beginning) of the mnttab file. The file modification time returned by <i>stat(2)</i> for the mnttab file is the time of the last change to mounted file system information. A <i>poll(2)</i> system call requesting a POLLRDBAND event can be used to

block and wait for the system's mounted file system information to be different from the most recent snapshot since the `mnttab` file was opened.

named.conf(4)

NAME	named.conf – configuration file for in.named																		
SYNOPSIS	<code>/etc/named.conf</code>																		
DESCRIPTION	<p>BIND version 8 is a much more configurable version than previous releases of BIND. New areas of configuration include access control lists and categorized logging. Many options that previously applied to all zones can now be used selectively. The new configuration file format in <code>named.conf</code> incorporates these features and allows for consideration of future configuration needs.</p>																		
General Syntax	<p>A BIND 8 configuration file consists of two general features, statements and comments.</p> <p>All statements end with a semicolon. Many statements allow substatements, which also terminate with a semicolon. BIND 8 supports the following statements:</p> <table><tr><td><code>logging</code></td><td>Specifies what the server logs, and where the log messages are sent.</td></tr><tr><td><code>options</code></td><td>Controls global server configuration options and sets defaults for other statements.</td></tr><tr><td><code>zone</code></td><td>Defines a zone.</td></tr><tr><td><code>acl</code></td><td>Defines a named IP address matching list, for access control and other uses.</td></tr><tr><td><code>key</code></td><td>Specifies key information for use in authentication and authorization.</td></tr><tr><td><code>trusted-keys</code></td><td>Defines DNSSEC keys that are preconfigured into the server and implicitly trusted.</td></tr><tr><td><code>server</code></td><td>Sets certain configuration options for individual remote servers.</td></tr><tr><td><code>controls</code></td><td>Declares control channels to be used by the <code>ndc(1M)</code> utility.</td></tr><tr><td><code>include</code></td><td>Includes another file.</td></tr></table> <p>The <code>logging</code> and <code>options</code> statements may only occur once per configuration, while the rest may appear numerous times. Further detail on each statement is provided in individual sections below.</p> <p>Comments may appear anywhere that whitespace may appear in a BIND configuration file. To appeal to programmers of all kinds, they can be written in C, C++, shell or perl constructs.</p> <p>C-style comments start with the two characters <code>/*</code> (slash, star) and end with <code>*/</code> (star, slash). Because comments are completely delimited by these characters, they can be used to comment either a portion of a line or to span multiple lines.</p> <p>C-style comments cannot be nested. For example, the following is not valid because the entire comment ends with the first <code>*/</code>:</p>	<code>logging</code>	Specifies what the server logs, and where the log messages are sent.	<code>options</code>	Controls global server configuration options and sets defaults for other statements.	<code>zone</code>	Defines a zone.	<code>acl</code>	Defines a named IP address matching list, for access control and other uses.	<code>key</code>	Specifies key information for use in authentication and authorization.	<code>trusted-keys</code>	Defines DNSSEC keys that are preconfigured into the server and implicitly trusted.	<code>server</code>	Sets certain configuration options for individual remote servers.	<code>controls</code>	Declares control channels to be used by the <code>ndc(1M)</code> utility.	<code>include</code>	Includes another file.
<code>logging</code>	Specifies what the server logs, and where the log messages are sent.																		
<code>options</code>	Controls global server configuration options and sets defaults for other statements.																		
<code>zone</code>	Defines a zone.																		
<code>acl</code>	Defines a named IP address matching list, for access control and other uses.																		
<code>key</code>	Specifies key information for use in authentication and authorization.																		
<code>trusted-keys</code>	Defines DNSSEC keys that are preconfigured into the server and implicitly trusted.																		
<code>server</code>	Sets certain configuration options for individual remote servers.																		
<code>controls</code>	Declares control channels to be used by the <code>ndc(1M)</code> utility.																		
<code>include</code>	Includes another file.																		

```

/* This is the start of a comment.
   This is still part of the comment.
/* This is an incorrect attempt at nesting a comment. */
   This is no longer in any comment. */

```

C++ style comments start with the two characters // (slash, slash) and continue to the end of the physical line. They cannot be continued across multiple physical lines. To have one logical comment span multiple lines, each line must use the // pair. For example:

```

// This is the start of a comment. The next line
// is a new comment, even though it is logically
// part of the previous comment.

```

Shell-style or perl-style comments start with the character # (hash or pound or number or octothorpe or whatever) and like C++ comments, continue to the end of the physical line. For example:

```

# This is the start of a comment. The next line
# is a new comment, even though it is logically
# part of the previous comment.

```

You can convert BIND 4.9.x configuration files to the new format by using `named-bootconf(1M)`.

Documentation Definitions

The elements described below are used throughout the BIND configuration file documentation. Elements which are only associated with one statement are described only in the section describing that statement.

<i>acl_name</i>	The name of an <i>address_match_list</i> as defined by the <code>acl</code> statement.
<i>address_match_list</i>	A list of one or more <i>ip_addr</i> , <i>ip_prefix</i> , <i>key_id</i> , or <i>acl_name</i> elements, as described in the ADDRESS MATCH LISTS section.
<i>dotted-decimal</i>	One or more integers valued 0 through 255 separated only by dots ("."), such as 123.45.67 or 89.123.45.67.
<i>domain_name</i>	A quoted string which will be used as a DNS name, for example "my.test.domain".
<i>path_name</i>	A quoted string which will be used as a pathname, such as "zones/master/my.test.domain".
<i>ip_addr</i>	An IP address in with exactly four elements in dotted-decimal notation.
<i>ip_port</i>	An IP port number. number is limited to 0 through 65535, with values below 1024 typically restricted to root-owned processes. In some cases an asterisk ("*") character can be used as a placeholder to select a random high-numbered port.
<i>ip_prefix</i>	IP network specified in dotted-decimal form, followed by "/" and then the number of bits in the netmask. For example, 127/8 is the network 127.0.0.0 with netmask 255.0.0.0. 1.2.3.0/28 is network 1.2.3.0 with netmask 255.255.255.240.

named.conf(4)

<i>key_name</i>	A string representing the name of a shared key, to be used for transaction security.
<i>number</i>	A non-negative integer with an entire range limited by the range of a C language signed integer (2,147,483,647 on a machine with 32 bit integers). Its acceptable value might be further limited by the context in which it is used.
<i>size_spec</i>	<p>number, the word <code>unlimited</code>, or the word <code>default</code>.</p> <p>The maximum value of <i>size_spec</i> is that of unsigned long integers on the machine. <code>unlimited</code> requests unlimited use, or the maximum available amount. <code>default</code> uses the limit that was in force when the server was started.</p> <p>A number can optionally be followed by a scaling factor: K or k for kilobytes, M or m for megabytes, and G or g for gigabytes, which scale by 1024, 1024*1024, and 1024*1024*1024 respectively.</p> <p>Integer storage overflow is currently silently ignored during conversion of scaled values, resulting in values less than intended, possibly even negative. Using <code>unlimited</code> is the best way to safely set a really large number.</p>
<i>yes_or_no</i>	Either <code>yes</code> or <code>no</code> . The words <code>true</code> and <code>false</code> are also accepted, as are the numbers 1 and 0.

Syntax

```
address_match_list    = 1*address_match_element

address_match_element = [ "!" ] ( address_match_list /
                                ip_address / ip_prefix /
                                acl_name / "key " key_id ) ";"
```

Definition and Usage

Address match lists are primarily used to determine access control for various server operations. They are also used to define priorities for querying other name servers and to set the addresses on which `in.named(1M)` `in.named` will listen for queries. The elements which constitute an address match list can be any of the following:

- an *ip-address* (in dotted-decimal notation)
- an *ip-prefix* (in the `'/'`-notation)
- A *key_id*, as defined by the key statement
- the name of an address match list previously defined with the `acl` statement
- or, another *address_match_list*.

Elements can be negated with a leading exclamation mark (`!"`), and the match list names `any`, `none`, `localhost` and `localnets` are predefined. More information on those names can be found in the description of the `acl` statement.

The addition of the `key` clause made the name of this syntactic element something of a misnomer, since security keys can be used to validate access without regard to a host

or network address. Nonetheless, the term “address match list” is still used throughout the documentation.

When a given IP address or prefix is compared to an address match list the list is traversed, in order, until an element matches. The interpretation of a match depends on whether the list is being used for access control, for defining listen-on ports, or as a topology, and whether the element is negated.

When used as an access control list, a non-negated match allows access, and a negated match denies access. If there is no match at all in the list, access is denied. The clauses `allow-query`, `allow-transfer`, `allow-update`, `allow-recursion` and `blackhole` all use address match lists like this. Similarly, the `listen-on` option will cause the server to not accept queries on any of the machine’s addresses that do not match the list.

When used with the `topology` option, a non-negated match returns a distance based on its position on the list. The closer the match is to the start of the list, the shorter the distance is between it and the server. A negated match will be assigned the maximum distance from the server. If there is no match, the address will get a distance which is further than any non-negated list element, and closer than any negated element.

Because of the first-match aspect of the algorithm, an element that defines a subset of another element in the list should come before the broader element, regardless of whether either is negated. For example, in

```
1.2.3/24; !1.2.3.13
```

the 1.2.3.13 element is completely useless, because the algorithm will match any lookup for 1.2.3.13 to the 1.2.3/24 element. Using

```
!1.2.3.13; 1.2.3/24
```

fixes that problem by having 1.2.3.13 blocked by the negation but all other 1.2.3.* hosts fall through.

Syntax

```
logging {
    [ channel channel_name {
        ( file path_name
          [ versions ( number | unlimited ) ]
          [ size size_spec ]
        | syslog ( kern | user | mail | daemon | auth | syslog | lpr |
                  news | uucp | cron | authpriv | ftp |
                  local0 | local1 | local2 | local3 |
                  local4 | local5 | local6 | local7 )
        | null );

        [ severity ( critical | error | warning | notice |
                   info | debug [ level ] | dynamic ); ]
        [ print-category yes_or_no; ]
        [ print-severity yes_or_no; ]
        [ print-time yes_or_no; ]
    }; ]

    [ category category_name {
        channel_name; [ channel_name; ... ]
    }
}
```

named.conf(4)

```
}; 1  
...  
};
```

Definition and Usage

The logging statement configures a wide variety of logging options for the name server. Its channel phrase associates output methods, format options and severity levels with a name that can then be used with the category phrase to select how various classes of messages are logged.

Only one logging statement is used to define as many channels and categories as are wanted. If there are multiple logging statements in a configuration, the first defined determines the logging, and warnings are issued for the others. If there is no logging statement, the logging configuration will be:

```
logging {  
    category default { default_syslog; default_debug; };  
    category panic { default_syslog; default_stderr; };  
    category packet { default_debug; };  
    category eventlib { default_debug; };  
};
```

The logging configuration is established as soon as the logging statement is parsed. If you want to redirect messages about processing of the entire configuration file, the logging statement must appear first. Even if you do not redirect configuration file parsing messages, we recommend always putting the logging statement first so that this rule need not be consciously recalled if you ever do want to relocate the parser's messages.

The Channel Phrase

All log output goes to one or more "channels." You can make as many of them as you want.

Every channel definition must include a clause that says whether messages selected for the channel go to a file, to a particular syslog(3C) facility, or are discarded. It can optionally also limit the message severity level that will be accepted by the channel (the default is info), and whether to include a time stamp generated by in.named(1M), the category name, or severity level. The default is not to include any of those three.

The word null as the destination option for the channel will cause all messages sent to it to be discarded. Other options for the channel are meaningless.

The file clause can include limitations both on how large the file is allowed to become and how many versions of the file will be saved each time the file is opened.

The size option for files is simply a hard ceiling on log growth. If the file ever exceeds the size, then in.named will not write anything more to it until the file is reopened. That the size is exceeded does not automatically trigger a reopen. The default behavior does not limit the size of the file.

If you use the version logfile option, then in.named will retain the backup versions of the file by renaming them when it opens them. For example, if you choose to keep 3 old versions of the file lamers.log then just before it is opened lamers.log.1 is

renamed to `lamers.log.2`, `lamers.log.0` is renamed to `lamers.log.1`, and `lamers.log` is renamed to `lamers.log.0`. No rolled versions are kept by default. Any existing log file is simply appended. The `unlimited` keyword is synonymous with `99` in current BIND releases. Example usage of `size` and `versions` options:

```
channel an_example_level {
    file "lamers.log" versions 3 size 20m;
    print-time yes;
    print-category yes;
};
```

The argument for the `syslog()` clause is a `syslog()` facility as described in the `syslog(3C)` manual page. How `syslogd(1M)` will handle messages sent to this facility is described in the `syslog.conf(4)`.

The *severity* clause works like the priority levels for `syslog()`, except that they can also be used if you are writing straight to a file rather than using `syslog()`. Messages which are not at least of the *severity* level given will not be selected for the channel; messages of higher *severity* levels will be accepted.

If you are using `syslog()`, then the `syslog.conf` priorities will also determine what eventually passes through. For example, defining a channel facility and severity as `daemon` and `debug` but only logging `daemon` warnings by means of `syslog.conf` will cause messages of severity `info` and `notice` to be dropped. If the situation were reversed, with `in.named` writing messages of only `warning` or higher, then `syslogd` will print all messages it receives from the channel.

The server can supply extensive debugging information when it is in debugging mode. If the server's global debug level is greater than zero, then the debugging mode will be active. The global debug level is set either by starting the `in.named` server with the `-d` flag followed by a positive integer, or by sending the running server the `SIGUSR1` signal (for example, by using `ndc trace`). The global debug level can be set to zero and debugging mode turned off, by sending the server the `SIGUSR2` signal (as with `ndc notrace`). All debugging messages in the server have a debug level, and higher debug levels give more more detailed output. Channels that specify a specific debug severity, for example:

```
channel specific_debug_level {
    file "foo";
    severity debug 3;
};
```

will get debugging output of level 3 or less any time the server is in debugging mode, regardless of the global debugging level. Channels with dynamic severity use the server's global level to determine what messages to print.

If `print-time` has been turned on, then the date and time will be logged. `print-time` may be specified for a `syslog()` channel, but is usually unnecessary since `syslog()` also prints the date and time. If `print-category` is requested, then the category of the message will be logged as well. Finally, if `print-severity` is on, then the severity level of the message will be logged. The `print-` options may be

named.conf(4)

used in any combination, and will always be printed in the following order: time, category, severity. Here is an example where all three `print-` options are on:

```
28-Apr-1997 15:05:32.863 default: notice: Ready to answer queries.
```

There are four predefined channels that are used for default logging in `named(1M)`. How they are used is described in the next section, The Category Phrase.

```
channel default_syslog {
    syslog daemon;      # send to syslog's daemon facility
    severity info;     # only send priority info and higher
};

channel default_debug {
    file "named.run";  # write to named.run in the working directory
                        # Note: stderr is used instead of "named.run"
                        # if the server is started with the -f option.
    severity dynamic;  # log at the server's current debug level
};

channel default_stderr { # writes to stderr
    file "<stderr>";    # this is illustrative only; there's currently
                        # no way of specifying an internal file
                        # descriptor in the configuration language.
    severity info;     # only send priority info and higher
};

channel null {
    null;              # toss anything sent to this channel
};
```

Once a channel is defined, it cannot be redefined. Thus you cannot alter the built-in channels directly, but you can modify the default logging by pointing categories at channels you have defined.

The Category Phrase

There are many categories, so you can send the logs you want to see wherever you want, without seeing logs you do not want. If you do not specify a list of channels for a category, then log messages in that category will be sent to the default category instead. If you do not specify a default category, the following "default default" is used:

```
category default { default_syslog; default_debug; };
```

To log security events to a file but also keep the default logging behavior, specify the following:

```
channel my_security_channel {
    file "my_security_file";
    severity info;
};
category security { my_security_channel;
                   default_syslog; default_debug; };
```

To discard all messages in a category, specify the null channel:

```
category lame-servers { null; };
category cname { null; };
```

The following categories are available:

default	The catch-all. Many things still are not classified into categories, and they all end up here. Also, if you don't specify any channels for a category, the default category is used instead. If you do not define the default category, the following definition is used <pre>category default { default_syslog; default_debug; };</pre>
config	High-level configuration file processing.
parser	Low-level configuration file processing.
queries	A short log message is generated for every query the server receives.
lame-servers	Messages like "Lame server on ..."
statistics	Statistics.
panic	If the server has to shut itself down due to an internal problem, it will log the problem in this category as well as in the problem's native category. If you do not define the panic category, the following definition is used: <pre>category panic { default_syslog; default_stderr; };</pre>
update	Dynamic updates.
ncache	Negative caching.
xfer-in	Zone transfers the server is receiving.
xfer-out	Zone transfers the server is sending
db	All database operations.
eventlib	Debugging information from the event system. Only one channel may be specified for this category, and it must be a file channel. If you do not define the eventlib category, the following definition is used: <pre>category eventlib { default_debug; };</pre>
packet	Dumps of packets received and sent. Only one channel may be specified for this category, and it must be a file channel. If you do not define the packet category, the following definition is used: <pre>category packet { default_debug; };</pre>
notify	The Notify protocol.
cname	Messages like "... points to a CNAME".
security	Approved or unapproved requests.

named.conf(4)

os	Operating system problems.
insist	Internal consistency check failures.
maintenance	Periodic maintenance events.
load	Load.
response-checks	Messages arising from response checking, such as "Malformed response ...", "wrong ans. name ...", "unrelated additional info ...", "invalid RR type ...", and "bad referral ...".

Definition and Usage

The options statement sets up global options to be used by BIND. This statement may appear only once in a configuration file. If more than one occurrence is found, the first occurrence determines the options used, and a warning will be generated. If there is no options statement, an options block with each option set to its default will be used.

Pathnames

version	The version the server should report by means of the <code>ndc(1M)</code> command or by means of a query of name <code>version.bind</code> in class <code>chaos</code> . The default is the real version number of the server.
directory	The working directory of the server. Any non-absolute pathnames in the configuration file will be taken as relative to this directory. The default location for most server output files, for example, <code>named.run</code> , is this directory. If a directory is not specified, the working directory defaults to <code>."</code> , the directory from which the server was started. The directory specified should be an absolute path.
named-xfer	The pathname to the <code>named-xfer</code> program that the server uses for inbound zone transfers. If not specified, the default is <code>/usr/sbin/named-xfer</code> .
dump-file	The pathname of the file to which the server dumps the database when it receives a <code>SIGINT</code> signal, for example, as sent by <code>ndc dump</code> . If not specified, the default is <code>named_dump.db</code> .
memstatistics-file	The pathname of the file the server writes memory usage statistics to on exit, if <code>deallocate-on-exit</code> is yes. If not specified, the default is <code>named.memstats</code> .
pid-file	The pathname of the file in which the server writes its process ID. If not specified, the default is <code>/var/run/named.pid</code> .
statistics-file	The pathname of the file the server appends statistics to when it receives a <code>SIGILL</code> signal. If not specified, the

Boolean Operations

		default is <code>named.stats</code> .
	<code>auth-nxdomain</code>	If the value is <code>yes</code> , then the AA bit is always set on NXDOMAIN responses, even if the server is not actually authoritative. The default is <code>yes</code> . Do not turn off <code>auth-nxdomain</code> unless you are sure you know what you are doing, as some older software will not like it.
	<code>deallocate-on-exit</code>	If the value is <code>yes</code> , then when the server exits it will painstakingly deallocate every object it allocated, and then write a memory usage report to the <code>memstatistics-file</code> . The default is <code>no</code> because it is faster to let the operating system clean up. <code>deallocate-on-exit</code> is handy for detecting memory leaks.
	<code>dialup</code>	If the value is <code>yes</code> , then the server treats all zones as if they are doing zone transfers across a dial on a demand dialup link, which can be brought up by traffic originating from this server. This has different effects according to the zone type. It concentrates the zone maintenance so that it all happens in a short interval, once every <code>heartbeat-interval</code> and hopefully, during the one call. It also suppresses some of the normal zone maintenance traffic. The default is <code>no</code> . The <code>dialup</code> option may also be specified in the zone statement, in which case it overrides the options <code>dialup</code> statement. If the zone is a master then the server will send out NOTIFY request to all the slaves. This will trigger the zone up to date checking in the slave, providing the slave supports NOTIFY, and allowing the slave to verify the zone while they call us up. If the zone is a slave or stub, then the server will suppress the regular zone up to date queries, and only perform them when the <i>heartbeat-interval</i> expires.
	<code>fake-iquery</code>	If <code>yes</code> , the server will simulate the obsolete DNS query type IQUERY. The default is <code>no</code> .
	<code>fetch-glue</code>	If <code>yes</code> (the default), the server will fetch "glue" resource records it does not have when it constructs the additional data section of a response. <code>fetch-glue no</code> can be used in conjunction with <code>recursion no</code> to prevent the server's cache from growing or becoming corrupted. However, it requires more work from the client.

has-old-clients	Setting the option to <code>yes</code> is equivalent to setting the following three options: <code>auth-nxdomain yes</code> , <code>maintain-ixfr-base yes</code> , and <code>rfc2308-type1 no</code> . <code>has-old-clients</code> with <code>auth-nxdomain</code> , <code>maintain-ixfr-base</code> , and <code>rfc2308-type1</code> is order dependant.
host-statistics	If <code>yes</code> , then statistics are kept for every host with which the name server interacts. The default is <code>no</code> . Turning on <code>host-statistics</code> can consume huge amounts of memory.
host-statistics-max	The maximum number of host records that will be kept. When this limit is reached no new hosts will be added to the host statistics. If <code>host-statistics-max</code> is set to zero, then there is no limit set. The default value is zero.
maintain-ixfr-base	If <code>yes</code> , a IXFR database file is kept for all dynamically updated zones. This enables the server to answer IXFR queries, which speeds up zone transfers enormously. The default value is <code>no</code> .
multiple-cnames	If <code>yes</code> , then multiple CNAME resource records will be allowed for a domain name. The default is <code>no</code> . Allowing multiple CNAME records is against standards and is not recommended. Multiple CNAME support is available because previous versions of BIND allowed multiple CNAME records, and these records have been used for load balancing by a number of sites.
notify	If <code>yes</code> (the default), DNS NOTIFY messages are sent when a zone for which the server is authoritative changes. The use of NOTIFY speeds convergence between the master and its slaves. Slave servers that receive a NOTIFY message and understand it will contact the master server for the zone and see if they need to do a zone transfer. If they do, they will initiate it immediately. The <code>notify</code> option may also be specified in the zone statement, in which case it overrides the options <code>notify</code> statement.
recursion	If <code>yes</code> , and a DNS query requests recursion, then the server will attempt to do all the work required to answer the query. If <code>recursion</code> is not on, the server will return a referral to the client if it does not know the answer. The default is <code>yes</code> . See also <code>fetch-glue</code> above.
rfc2308-type1	If <code>yes</code> , the server will send NS records along with the SOA record for negative answers. If you have an old

		<p>BIND server using you as a forwarder, which does not understand negative answers that contain both SOA and NS records, or you have an old version of <code>sendmail(1M)</code>, set this to <code>no</code>. The correct fix is to upgrade the broken server or <code>sendmail</code>. The default is <code>no</code>.</p>
	<code>use-id-pool</code>	<p>If <code>yes</code>, the server will keep track of its own outstanding query ID's to avoid duplication and increase randomness. As a result, the server will consume 128KB more memory. The default is <code>no</code>.</p>
	<code>treat-cr-as-space</code>	<p>If <code>yes</code>, the server will treat CR characters the same way it treats a space or tab. This may be necessary when loading zone files on a UNIX system that were generated on either an NT or a DOS machine. The default is <code>no</code>.</p>
Also-Notify	<code>also-notify</code>	<p>Defines a global list of IP addresses that also get sent NOTIFY messages whenever a fresh copy of the zone is loaded. This helps to ensure that copies of the zones will quickly converge on "stealth" servers. If an <code>also-notify</code> list is given in a zone statement, it will override the options <code>also-notify</code> statement. When a zone notify statement is set to <code>no</code>, the IP addresses in the global <code>also-notify</code> list will not get sent NOTIFY messages for that zone. The default is the empty list (no global notification list).</p>
Forwarding		<p>The forwarding facility can be used to create a large site-wide cache on a few servers. This reduces traffic over links to external name servers. It can also be used to allow queries by servers that do not have direct access to the Internet but wish to look up exterior names anyway. Forwarding occurs only on those queries for which the server is not authoritative and does not have the answer in its cache.</p>
	<code>forward</code>	<p>This option is only meaningful if the forwarders list is not empty. A value of <code>first</code>, the default, causes the server to query the forwarders first. If the forwarders do not answer the question, the server will then look for the answer itself. If <code>only</code> is specified, the server will only query the forwarders.</p>
	<code>forwarders</code>	<p>Specifies the IP addresses to be used for forwarding. The default is the empty list (no forwarding).</p>
		<p>Forwarding can also be configured on a per-zone basis, allowing for the global forwarding options to be overridden in a variety of ways. You can set particular zones to use different forwarders, have different <code>forward only</code> or <code>forward first</code> behavior, or not forward at all. See THE ZONE STATEMENT section for more information.</p>
		<p>Future versions of BIND 8 may provide a more powerful forwarding system. The syntax described above will continue to be supported.</p>

Name Checking

The server can check domain names based upon their expected client contexts. For example, a domain name used as a hostname can be checked for compliance with the RFCs that define valid hostnames.

Three checking methods are available:

- `ignore` No checking is done.
- `warn` Names are checked against their expected client contexts. Invalid names are logged, but processing continues normally.
- `fail` Names are checked against their expected client contexts. Invalid names are logged, and the offending data is rejected.

The server can check names three areas: master zone files, slave zone files, and responses to queries the server has initiated. If `check-names` response `fail` has been specified, and to answer the client's question would require sending an invalid name to the client, the server will send a `REFUSED` response code to the client.

The defaults are:

- `check-names master fail`
- `check-names slave warn`
- `check-names response ignore`

`check-names` may also be specified in the zone statement, in which case it overrides the options `check-names` statement. When used in a zone statement, the area is not specified, as it can be deduced from the zone type.

Access Control

Access to the server can be restricted based on the IP address of the requesting system or by means of shared secret keys. See `ADDRESS MATCH LISTS` for details on how to specify access criteria.

- `allow-query` Specifies which hosts are allowed to ask ordinary questions. `allow-query` may also be specified in the zone statement, in which case it overrides the options `allow-query` statement. If not specified, the default is:
 - `allow-recursion` Specifies which hosts are allowed to ask recursive questions. `allow-recursion` may also be specified in the zone statement, in which case it overrides the options `allow-recursion` statement. If not specified, the default is to allow recursive queries from all hosts.
 - `allow-transfer` Specifies which hosts are allowed to receive zone transfers from the server. `allow-transfer` may also be specified in the zone statement, in which case it overrides the options `allow-transfer`

named.conf(4)

		statement. If not specified, the default is to allow transfers from all hosts.
	<code>blackhole</code>	Specifies a list of addresses that the server will not accept queries from or use to resolve a query. Queries from these addresses will not receive a response.
Interfaces	<p>The interfaces and ports that the server will answer queries from may be specified using the <code>listen-on</code> option. <code>listen-on</code> takes an optional port and an address match list. The server will listen on all interfaces allowed by the address match list. If a port is not specified, port 53 will be used.</p> <p>Multiple <code>listen-on</code> statements are allowed. For example,</p> <pre>listen-on { 5.6.7.8; }; listen-on port 1234 { !1.2.3.4; 1.2/16; };</pre> <p>will enable the name server on port 53 for the IP address 5.6.7.8, and on port 1234 of an address on the machine in net 1.2 that is not 1.2.3.4.</p> <p>If no <code>listen-on</code> is specified, the server will listen on port 53 on all interfaces.</p>	
Query Address	<p>If the server does not know the answer to a question, it will query other name servers. <code>query-source</code> specifies the address and port used for such queries. If address is <code>*</code> or is omitted, a wildcard IP address (<code>INADDR_ANY</code>) will be used. If port is <code>*</code> or is omitted, a random unprivileged port will be used. The default is</p> <pre>query-source address * port *;</pre> <p><code>query-source</code> currently applies only to UDP queries; TCP queries always use a wildcard IP address and a random unprivileged port.</p>	
Zone Transfers	<p><code>max-transfer-time-in</code> Inbound zone transfers (<code>named-xfer</code> processes) running longer than <code>max-transfer-time-in</code> minutes will be terminated. The default value for <code>max-transfer-time-in</code> is 120 minutes (2 hours).</p> <p><code>transfer-format</code> The server supports two zone transfer methods. <code>one-answer</code> uses one DNS message per resource record transferred. <code>many-answers</code> packs as many resource records as possible into a message. <code>many-answers</code> is more efficient, but is only known to be understood by BIND 8.1 and patched versions of BIND 4.9.5. The default is <code>one-answer</code>. <code>transfer-format</code> may be overridden on a per-server basis by using the server statement.</p> <p><code>transfers-in</code> The maximum number of inbound zone transfers that can be running concurrently. The default value is 10. Increasing <code>transfers-in</code> may speed up the</p>	

	convergence of slave zones, but it also may increase the load on the local system.
<code>transfers-out</code>	This option will be used in the future to limit the number of concurrent outbound zone transfers. It is checked for syntax, but is otherwise ignored.
<code>transfers-per-ns</code>	The maximum number of inbound zone transfers (<code>named-xfer</code> processes) that can be concurrently transferred from a given remote name server. The default value is 2. Increasing <code>transfers-per-ns</code> may speed up the convergence of slave zones, but it also may increase the load on the remote name server. <code>transfers-per-ns</code> may be overridden on a per-server basis by using the <code>transfers</code> phrase of the server statement.
<code>transfer-source</code>	<code>transfer-source</code> determines which local address will be bound to the TCP connection used to fetch all zones transferred inbound by the server. If not set, it defaults to a system controlled value which will usually be the address of the interface “closest to” the remote end. This address must appear in the remote end’s <code>allow-transfer</code> option for the zones being transferred, if one is specified. This statement sets the <code>transfer-source</code> for all zones, but can be overridden on a per-zone basis by including a <code>transfer-source</code> statement within the zone block in the configuration file.

Resource Limits

The server’s usage of many system resources can be limited. Some operating systems do not support some of the limits. On such systems, a warning will be issued if the unsupported limit is used. Some operating systems do not support resource limits, and on these systems a

```
set resource limits on this system
will be logged.
```

Scaled values are allowed when specifying resource limits. For example, 1G can be used instead of 1073741824 to specify a limit of one gigabyte. Other values include: `unlimited requests`, `unlimited use`, or the maximum available amount. The value `default` uses the limit that was in force when the server was started. See the definition of `size_spec` for more details.

<code>coresize</code>	The maximum size of a core dump. The default value is <code>default</code> .
<code>datasize</code>	The maximum amount of data memory the server may use. The default value is <code>default</code> .

named.conf(4)

	<code>files</code>	The maximum number of files the server may have open concurrently. The default value is <code>unlimited</code> . Note that on some operating systems the server cannot set an unlimited value and cannot determine the maximum number of open files the kernel can support. On such systems, choosing <code>unlimited</code> will cause the server to use the larger of the <code>rlim_max</code> from <code>getrlimitRLIMIT_NOFILE()</code> and the value returned by <code>sysconf_SC_OPEN_MAX()</code> . If the actual kernel limit is larger than this value, use <code>limit files</code> to specify the limit explicitly.
	<code>max-ixfr-log-size</code>	The <code>max-ixfr-log-size</code> will be used in a future release of the server to limit the size of the transaction log kept for Incremental Zone Transfer.
	<code>stacksize</code>	The maximum amount of stack memory the server may use. The default value is <code>default</code> .
Periodic Task Intervals	<code>cleaning-interval</code>	The server will remove expired resource records from the cache every <code>cleaning-interval</code> minutes. The default is 60 minutes. If set to 0, no periodic cleaning will occur.
	<code>heartbeat-interval</code>	The server will perform zone maintenance tasks for all zones marked <code>dialup yes</code> whenever this interval expires. The default is 60 minutes. Reasonable values are up to 1 day (1440 minutes). If set to 0, no zone maintenance for these zones will occur.
	<code>interface-interval</code>	The server will scan the network interface list every <code>interface-interval</code> minutes. The default is 60 minutes. If set to 0, interface scanning will only occur when the configuration file is loaded. After the scan, listeners will be started on any new interfaces, provided they are allowed by the <code>listen-on</code> configuration.. Listeners on interfaces that have gone away will be cleaned up.
	<code>statistics-interval</code>	Name server statistics will be logged every <code>statistics-interval</code> minutes. The default is 60. If set to 0, no statistics will be logged.
	Topology	All other things being equal, when the server chooses a name server to query from a list of name servers, it prefers the one that is topologically closest to itself. The <code>topology</code> statement takes an address match list and interprets it in a special way. Each top-level list element is assigned a distance. Non-negated elements get a distance based on their position in the list, where the closer the match is to the start of the list, the shorter the distance is between it and the server. A negated match will be assigned the maximum distance from the server. If there is no match, the address will get a

distance which is further than any non-negated list element, and closer than any negated element. For example:

```
topology {
    10/8;
    !1.2.3/24;
    { 1.2/16; 3/8; };
};
```

will prefer servers on network 10, followed by hosts on network 1.2.0.0 (netmask 255.255.0.0) and network 3, with the exception of hosts on network 1.2.3 (netmask 255.255.255.0), which is the least preferred.

The default topology is:

```
topology { localhost; localnets; };
```

Resource Record Sorting

When returning multiple resource records (“RRs”), the name server will normally return them in round robin, that is, after each request, the first RR is put to the end of the list. As the order of RRs is not defined, this should not cause any problems.

The client resolver code should rearrange the RRs as appropriate, for example, using any addresses on the local network before other addresses. However, not all resolvers can do this, or are not correctly configured to do so.

When a client is using a local server, the sorting can be performed by the server, based on the client’s address. This only requires configuring the name servers, not all the clients.

The `sortlist` statement takes an address match list and interprets it even more specially than the `topology` statement does.

Each top level statement in the `sortlist` must itself be an explicit address match list with one or two elements. The first element of each top level list, which may be an IP address, an IP prefix, an acl name or nested address match list, is checked against the source address of the query until a match is found.

Once the source address of the query has been matched, if the top level statement contains only one element, the actual primitive element that matched the source address is used to select the address in the response to move to the beginning of the response. If the statement is a list of two elements, the second element is treated like the address match list in a `topology` statement. Each top level element is assigned a distance and the address in the response with the minimum distance is moved to the beginning of the response.

In the following example, any queries received from any of the addresses of the host itself will get responses that prefer addresses on any of the locally connected networks. Next most preferred are addresses on the 192.168.1/24 network, and after that either the 192.168.2/24 or 192.168.3/24 network with no preference shown between these two networks. Queries received from a host on the 192.168.1/24 network will prefer other addresses on that network to the 192.168.2/24 and

named.conf(4)

192.168.3/24 networks. Queries received from a host on the 192.168.4/24 or the 192.168.5/24 network will only prefer other addresses on their directly connected networks.

```
sortlist {
    { localhost;          // IF the local host
      { localnets;      // THEN first fit on the
        192.168.1/24;    // following nets
        { 192.168.2/24; 192.168.3/24; }; }; };
    { 192.168.1/24;     // IF on class C 192.168.1
      { 192.168.1/24;   // THEN use .1, or .2 or .3
        { 192.168.2/24; 192.168.3/24; }; }; };
    { 192.168.2/24;    // IF on class C 192.168.2
      { 192.168.2/24;   // THEN use .2, or .1 or .3
        { 192.168.1/24; 192.168.3/24; }; }; };
    { 192.168.3/24;    // IF on class C 192.168.3
      { 192.168.3/24;   // THEN use .3, or .1 or .2
        { 192.168.1/24; 192.168.2/24; }; }; };
    { { 192.168.4/24; 192.168.5/24; }; // if .4 or .5,
                                          // prefer that net
    };
};
```

The following example will give reasonable behavior for the local host and hosts on directly connected networks. It is similar to the behavior of the address sort in BIND 4.9.x. Responses sent to queries from the local host will favor any of the directly connected networks. Responses sent to queries from any other hosts on a directly connected network will prefer addresses on that same network. Responses to other queries will not be sorted.

```
sortlist {
    { localhost; localnets; };
    { localnets; };
};
```

RRset Ordering

When multiple records are returned in an answer it may be useful to configure the order the records are placed into the response. For example the records for a zone might be configured to always be returned in the order they are defined in the zone file. Perhaps you want a random shuffle of the records as they are returned. The `rrset-order` statement permits you to configure the order of the records in a multiple record response. The default, if no ordering is defined, is a `cyclic` ordering (round robin).

An `order_spec` is defined as follows:

```
[ class class_name ][ type type_name ][ name "FQDN" ] order ordering
```

If no class is specified, the default is `ANY`. If no type is specified, the default is `ANY`. If no name is specified, the default is `"*"`.

The legal values for ordering are:

`fixed` Records are returned in the order they are defined in the zone file.

`random` Records are returned in some random order.

`cyclic` Records are returned in a round-robin order.

For example:

```
rrset-order {
    class IN type A name "rc.vix.com" order random;
    order cyclic;
};
```

will cause any responses for type A records in class IN that have "rc.vix.com" as a suffix, to always be returned in random order. All other records are returned in cyclic order.

If multiple `rrset-order` statements appear, they are not combined. The last one applies.

If no `rrset-order` statement is specified, the following default statement is used:

```
rrset-order { class ANY type ANY name "*" order cyclic ; };
```

Tuning

`lame-ttl` Sets the number of seconds to cache a lame server indication. 0 disables caching. The default is 600 (10 minutes). The maximum value is 1800 (30 minutes).

`max-ncache-ttl` To reduce network traffic and increase performance, the server store negative answers. `max-ncache-ttl` is used to set a maximum retention time for these answers in the server in seconds. The default `max-ncache-ttl` is 10800 seconds (3 hours). `max-ncache-ttl` cannot exceed the maximum retention time for ordinary (positive) answers (7 days) and will be silently truncated to 7 days if set to a value which is greater than 7 days.

`min-roots` The minimum number of root servers that is required for a request for the root servers to be accepted. The default is 2.

Syntax

```
zone domain_name [ ( in | hs | hesiod | chaos ) ] {
    type master;
    file path_name;
    [ check-names ( warn | fail | ignore ); ]
    [ allow-update { address_match_list }; ]
    [ allow-query { address_match_list }; ]
    [ allow-transfer { address_match_list }; ]
    [ forward ( only | first ); ]
    [ forwarders { [ip_addr; [ip_addr; ... ] ] }; ]
    [ dialup yes_or_no; ]
    [ notify yes_or_no; ]
    [ also-notify { ip_addr; [ ip_addr; ... ] }; ]
    [ pubkey number number number string; ]
};

zone domain_name [ ( in | hs | hesiod | chaos ) ] {
    type ( slave | stub );
```

named.conf(4)

```
[ file path_name; ]
masters [ port ip_port ] { ip_addr; [ ip_addr; ... ] };
[ check-names ( warn | fail | ignore ); ]
[ allow-update { address_match_list }; ]
[ allow-query { address_match_list }; ]
[ allow-transfer { address_match_list }; ]
[ forward ( only | first ); ]
[ forwarders { [ ip_addr; [ ip_addr; ... ] ] }; ]
[ transfer-source ip_addr; ]
[ max-transfer-time-in number; ]
[ notify yes_or_no; ]
[ also-notify { ip_addr; [ ip_addr; ... ] }; ]
[ pubkey number number number string; ]
};

zone domain_name [ ( in | hs | hesiod | chaos ) ] {
    type forward;
    [ forward ( only | first ); ]
    [ forwarders { [ ip_addr ; [ ip_addr ; ... ] ] }; ]
    [ check-names ( warn | fail | ignore ); ]
};

zone "." [ ( in | hs | hesiod | chaos ) ] {
    type hint;
    file path_name;
    [ check-names ( warn | fail | ignore ); ]
};
```

Definition and Usage

The zone statement is used to define how information about particular DNS zones is managed by the server. There are five different zone types.

master	The server has a master copy of the data for the zone and will be able to provide authoritative answers for it.
slave	A slave zone is a replica of a master zone. The masters list specifies one or more IP addresses that the slave contacts to update its copy of the zone. If a port is specified, it then checks to see if the zone is current and makes zone transfers to the port given. If a file is specified, then the replica will be written to the named file. Use of the file clause is highly recommended, since it often speeds server startup and eliminates a needless waste of bandwidth.
stub	A stub zone is like a slave zone, except that it replicates only the NS records of a master zone instead of the entire zone.
forward	A forward zone is used to direct all queries in it to other servers, as described in THE OPTIONS STATEMENT section. The specification of options in such a zone will override any global options declared in the options statement.

If no forwarders clause is present in the zone or an empty list for forwarders is given, then no forwarding will be done for the zone, cancelling the effects of any forwarders in the options statement. Thus if you want to use this type of zone to change only the

		behavior of the global forward option, and not the servers used, then you also need to respecify the global forwarders.
	hint	The initial set of root name servers is specified using a hint zone. When the server starts up, it uses the root hints to find a root name server and get the most recent list of root name servers.
		Previous releases of BIND used the term <i>primary</i> for a master zone, <i>secondary</i> for a slave zone, and <i>cache</i> for a hint zone.
Classes		The zone's name may optionally be followed by a class. If a class is not specified, class <i>in</i> (for "internet"), is assumed. This is correct for the vast majority of cases.
		The <i>hesiod</i> class is for an information service from MIT's Project Athena. It is used to share information about various systems databases, such as users, groups, and printers. More information can be found at ftp://athena-dist.mit.edu/pub/ATHENA/usenix/athena_changes.PS . The keyword <i>hs</i> is a synonym for <i>hesiod</i> .
		Another MIT development was CHAOSnet, a LAN protocol created in the mid-1970s. It is still sometimes seen on LISP stations and other hardware in the AI community, and zone data for it can be specified with the <i>chaos</i> class.
Options	check-names	See the subsection on Name Checking in THE OPTIONS STATEMENT.
	allow-query	See the description of allow-query in the Access Control subsection of THE OPTIONS STATEMENT.
	allow-update	Specifies which hosts are allowed to submit dynamic DNS updates to the server. The default is to deny updates from all hosts.
	allow-transfer	See the description of allow-transfer in the Access Control subsection of THE OPTIONS STATEMENT.
	transfer-source	<i>transfer-source</i> determines which local address will be bound to the TCP connection used to fetch this zone. If not set, it defaults to a system controlled value which will usually be the address of the interface "closest to" the remote end. This address must appear in the remote end's <i>allow-transfer</i> option for this zone if one is specified.
	max-transfer-time-in	See the description of max-transfer-time-in in the Zone Transfers subsection of THE OPTIONS STATEMENT.
	dialup	See the description of dialup in the Boolean Options subsection of THE OPTIONS STATEMENT.

named.conf(4)

	<code>notify</code>	See the description of <code>notify</code> in the Boolean Options subsection of the THE OPTIONS STATEMENT.
	<code>also-notify</code>	<code>also-notify</code> is only meaningful if <code>notify</code> is active for this zone. The set of machines that will receive a DNS NOTIFY message for this zone is made up of all the listed name servers for the zone (other than the primary master), plus any IP addresses specified with <code>also-notify</code> . <code>also-notify</code> is not meaningful for stub zones. The default is the empty list.
	<code>forward</code>	<code>forward</code> is only meaningful if the zone has a forwarders list. The only value causes the lookup to fail after trying the forwarders and getting no answer, while <code>first</code> would allow a normal lookup to be tried.
	<code>forwarders</code>	The <code>forwarders</code> option in a zone is used to override the list of global forwarders. If it is not specified in a zone of type <code>forward</code> , no forwarding is done for the zone, and the global options are not used.
	<code>pubkey</code>	The DNSSEC flags, protocol, and algorithm are specified, as well as a base-64 encoded string representing the key.
Syntax	<pre>acl name { address_match_list };</pre>	
Definition and Usage		The <code>acl</code> statement creates a named address match list. It gets its name from a primary use of address match lists: Access Control Lists (acls). An address match list's name must be defined with <code>acl</code> before it can be used elsewhere. No forward references are allowed. The following acls are built-in: <code>any</code> Allows all hosts. <code>none</code> Denies all hosts. <code>localhosts</code> Allows the IP addresses of all interfaces on the system. <code>localnets</code> Allows any host on a network for which the system has an interface.
Syntax	<pre>key key_id { algorithm algorithm_id; secret secret_string; };</pre>	
Definition and Usage		The <code>key</code> statement defines a key ID which can be used in a server statement to associate with a particular name server a method of authentication that is more

rigorous than simple IP address matching. A key ID must be created with the key statement before it can be used in a server definition or an address match list.

The `algorithm_id` is a string that specifies a security/authentication algorithm. `secret_string` is the secret to be used by the algorithm, and is treated as a base-64 encoded string. If you have a `secret_string` in your `named.conf` file, make sure that it is not be readable by anyone beside superuser.

Syntax

```
trusted-keys {
    [ domain_name flags protocol algorithm key; ]
};
```

Definition and Usage

The `trusted-keys` statement is for use with DNSSEC-style security, originally specified in *RFC 2065*. DNSSEC is meant to provide three distinct services: key distribution, data origin authentication, and transaction and request authentication.

The contributed section of the ISC BIND distribution includes a `dns_signer` utility to sign zone data according to the DNSSEC specifications. The utility is provided as-is, without any expressed or implied warranties. The contributed source could be retrieved from the `/isc/bind/src/cur/bind-8` directory at ISC's FTP site, `ftp.isc.org`.

Each trusted key is associated with a domain name. Its attributes are the non-negative integral flags, protocol, and algorithm, as well as a base-64 encoded string representing the key.

Any number of trusted keys can be specified.

Syntax

```
server ip_addr {
    [ bogus yes_or_no; ]
    [ transfers number; ]
    [ transfer-format ( one-answer | many-answers ); ]
    [ keys { key_id [ key_id ... ] }; ]
};
```

Definition and Usage

The `server` statement defines the characteristics to be associated with a remote name server.

If you discover that a server is giving out bad data, marking it as bogus will prevent further queries to it. The default value of bogus is no.

If you mark a server as bogus, all other addresses for that server will be marked as bogus when a match is made when looking up a server's address by name.

The server supports two zone transfer methods. The first, `one-answer`, uses one DNS message per resource record transferred. The second method, `many-answers` packs as many resource records as possible into a message. `many-answers` is more efficient, but is only understood by BIND 8.1 and patched versions of BIND 4.9.5. You can specify which method to use for a server with the `transfer-format` option. If `transfer-format` is not specified, the `transfer-format` specified by the options statement will be used.

named.conf(4)

The `transfers` will be used in a future release of the server to limit the number of concurrent in-bound zone transfers from the specified server. It is checked for syntax but is otherwise ignored.

The `key` clause is used to identify a `key_id` defined by the `key` statement, to be used for transaction security when talking to the remote server. The `key` statement must come before the server statement that references it.

The `key` statement is intended for future use by the server. It is checked for syntax but is otherwise ignored.

Syntax

```
controls {
  [ inet ip_addr
    port ip_port
    allow { address_match_list; }; ]
  [ unix path_name
    perm number
    owner number
    group number; ]
};
```

Definition and Usage

The `controls` statement declares control channels to be used by system administrators to affect the operation of the local name server. These control channels are used by the `ndc(1M)` utility to send commands to and retrieve non-DNS results from a name server.

A UNIX control channel is a FIFO in the file system, and access to it is controlled by normal file system permissions. It is created by `in.named(1M)` with the specified file mode bits, user and group owner. See `chmod(1)`. Note that, unlike `chmod`, the mode bits specified for `perm` will normally have a leading 0 so the number is interpreted as octal. Also note that the user and group ownership specified as `owner` and `group` must be given as numbers, not names. It is recommended that the permissions be restricted to administrative personnel only, or else any user on the system may be able to manage the local name server.

An `inet` control channel is a TCP/IP socket accessible to the Internet, created at the specified `ip_port` on the specified `ip_addr`. Modern telnet clients are capable of speaking directly to these sockets, and the control protocol is ARPAnet-style text. It is recommended that 127.0.0.1 be the only `ip_addr` used, and this only if you trust all non-privileged users on the local host to manage your name server.

Syntax

```
include path_name;
```

Definition and Usage

The `include` statement inserts the specified file at the point that the `include` statement is encountered. It cannot be used within another statement, though, so a line such as

```
acl internal_hosts { include internal_hosts.acl; };
```

is not allowed.

Use include to break the configuration up into easily-managed chunks. For example:

```
include "/etc/security/keys.bind";
include "/etc/acls.bind";
```

could be used at the top of a BIND configuration file in order to include any acl or key information.

Be careful not to use "#include," like you would in a C program, because "#" is used to start a comment.

EXAMPLES **EXAMPLE 1** Simple Configuration File

The simplest configuration file that is still realistically useful is one which simply defines a hint zone that has a full path to the root servers file, for example:

```
zone "." in {
    type hint;
    file "/var/named/root.cache";
};
```

EXAMPLE 2 Another Example of a Configuration File

Here is a more typical real-world example.

```
/*
 * A simple BIND 8 configuration
 */

logging {
    category lame-servers { null; };
    category cname { null; };
};

options {
    directory "/var/named";
};

controls {
    inet * port 52 allow { any; }; // a bad idea
    unix "/var/run/ndc" perm 0600 owner 0 group 0; // the default
};

zone "isc.org" in {
    type master;
    file "master/isc.org";
};

zone "vix.com" in {
    type slave;
    file "slave/vix.com";
    masters { 10.0.0.53; };
};
```

named.conf(4)

EXAMPLE 2 Another Example of a Configuration File (Continued)

```
zone "0.0.127.in-addr.arpa" in {
    type master;
    file "master/127.0.0";
};

zone "." in {
    type hint;
    file "root.cache";
};
```

FILES /etc/named.conf The BIND 8 in.named configuration file.

NAME	ncad_addr – name of the Solaris Network Cache and Accelerator (NCA) socket utility library
SYNOPSIS	<code>/usr/lib/ncad_addr.so</code>
DESCRIPTION	<p><code>ncad_addr.so</code> is the Solaris Network Cache and Accelerator (NCA) socket utility library. Use this library with a web server to avoid support for the <code>PF_NCA</code> family type socket. The web server can take advantage of NCA functionality.</p> <p>Interpose the <code>ncad_addr</code> interfaces before the interfaces in <code>libsocket</code> by setting the environment variable <code>LD_PRELOAD</code> to <code>ncad_addr.so</code> so that it is preloaded before <code>libsocket.so.1</code>. The <code>ncad_addr.so</code> interfaces will be interposed only if NCA is enabled. See <code>ncakmod(1)</code>.</p>
EXAMPLES	<p>EXAMPLE 1 Interposing <code>ncad_addr</code></p> <p>Using Bourne shell syntax as an example, set <code>LD_PRELOAD</code> as shown below to interpose the <code>ncad_addr</code> socket utility library:</p> <pre>LD_PRELOAD=/usr/lib/ncad_addr.so /usr/bin/httpd</pre>
FILES	<code>/usr/lib/ncad_addr.so</code> <code>ncad_addr</code> socket utility library shared object

NOTES	Only applications that use the NCA feature, for example, web servers, should interpose this library.

nca.if(4)

NAME	nca.if – the NCA configuration file that specifies physical interfaces	
SYNOPSIS	/etc/nca/nca.if	
DESCRIPTION	<p>Specify the physical interfaces for which the Solaris Network Cache and Accelerator (“NCA”) feature will be configured in the <code>nca.if</code> configuration file. List the physical interfaces in the file, one per line. To configure NCA to listen on all physical interfaces present on the system backed by a <code>hostname.{interface_name}</code>, then list only an asterisk (“*”) in <code>nca.if</code>.</p> <p>When the <code>ncakmod(1)</code> initialization script is invoked during system boot, it will attempt to configure each physical interface specified in the <code>nca.if</code> file by using <code>ncaconfd(1M)</code>. Note that there must be an accompanying <code>hostname.{interface_name}</code> file and an entry in <code>/etc/hosts</code> for the contents of <code>hostname.{interface_name}</code>.</p> <p>You must reboot in order to implement changes to the <code>nca.if</code> file.</p>	
IA	EXAMPLE 1	nca.if on IA
	The following is an example of an <code>nca.if</code> file that would be used on an IA system:	
	<pre>iprb1 iprb6 iprb8</pre>	
SPARC	EXAMPLE 2	nca.if on SPARC
	The following is an example of an <code>nca.if</code> file that would be used on a SPARC system:	
	<pre>hme2 hme3 hme4</pre>	
All Platforms	EXAMPLE 3	Configuring NCA to Listen on All Physical Interfaces
	The following example shows the contents of an <code>nca.if</code> file that would be used to configure either platform to listen on all physical interfaces present on the system:	
	<pre>*</pre>	
FILES	<code>/etc/nca/nca.if</code>	Lists the physical interfaces on which NCA will run.
	<code>/etc/hostname.{0-9}</code>	Lists all physical interfaces configured on the server.
	<code>/etc/hosts</code>	Lists all host names associated with the server. Entries in this file must match with entries in <code>/etc/hostname.{0-9}</code> for NCA to function.

ncakmod.conf(4)

NAME	ncakmod.conf – the ncakmod configuration file		
SYNOPSIS	/etc/nca/ncakmod.conf		
DESCRIPTION	<p>The <code>ncakmod.conf</code> file is used to configure the Solaris Network Cache and Accelerator (“NCA”) kernel module. The file contains two fields, <code>key</code> and <code>value</code>.</p> <p>The <code>status</code> key is used to indicate if the user wants to have NCA turned on as a feature. If the value of <code>status</code> key is <code>enabled</code>, then the NCA kernel module will be pushed on to the specified interfaces. If the value of the <code>status</code> key is <code>disabled</code>, then the NCA kernel module will not be pushed on to any interfaces. The default is <code>disabled</code>.</p> <p>The <code>httpd_door_path</code> key specifies the path name of the Solaris Door RPC mechanism that will be used to communicate with the <code>http</code> daemon. The default value is <code>/var/run/nca_httpd_1.door</code>.</p> <p>Use the <code>nca_active</code> key to indicate whether to allow NCA to actively open outgoing TCP connections. The default value for <code>nca_active</code> is <code>disabled</code>. If set to <code>enabled</code>, <code>ncaconfd</code> sets up NCA for each interface and then operates as a daemon, allowing NCA to make outgoing TCP connections. This functionality is possible only by using the <code>doors</code> interface to NCA. A web server that uses the <code>sockets</code> interface with <code>PF_NCA</code> or <code>ncad_addr.so</code> cannot connect by means of <code>nca_active</code>.</p> <p>NCA supports the logging of in-kernel cache hits. See <code>ncalogd.conf(4)</code>. NCA stores logs in a binary format. Use the <code>ncab2clf(1)</code> utility to convert the log from a binary format to the Common Log File format.</p> <p>In order to implement changes to the <code>ncakmod.conf</code> file, you will need to reboot.</p>		
EXAMPLES	<p>EXAMPLE 1 A Sample <code>ncakmod.conf</code> File</p> <p>The following is a sample <code>ncakmod.conf</code> file:</p> <pre># # NCA Kernel Module Configuration File # status=disabled httpd_door_path=/var/run/nca_httpd_1.door nca_active=disabled</pre>		
FILES	<table><tr><td>/etc/nca/ncakmod.conf</td><td>The NCA kernel module configuration file.</td></tr></table>	/etc/nca/ncakmod.conf	The NCA kernel module configuration file.
/etc/nca/ncakmod.conf	The NCA kernel module configuration file.

ncaologd.conf(4)

NAME	ncaologd.conf – NCA logging configuration file		
SYNOPSIS	/etc/nca/ncaologd.conf		
DESCRIPTION	<p>The <code>ncaologd.conf</code> is used to configure Solaris Network Cache and Accelerator (“NCA”) logging. The file contains two fields, <code>key</code> and <code>value</code>.</p> <p>The <code>status</code> key is used to indicate if the user wants to have NCA logging turned on. If the value of <code>status</code> key is <code>enabled</code>, then NCA logging will be turned on. If the value of the <code>status</code> key is <code>disabled</code>, then NCA logging will not be invoked. The default value is <code>disabled</code>.</p> <p>The <code>logd_path_name</code> key specifies the location of the log file. The value of <code>logd_path_name</code> is the absolute path to the log file. The default value is <code>/var/nca/log</code>. <code>logd_path_name</code> can also contain a white space delimited list of values for multiple log files to a maximum of 16. NCA logging moves to the next file on the list once the file size specified by <code>logd_file_size</code> has been reached. When the last file is full, NCA logging rotates back to the first file in the list. A pointer to the current log file is stored in <code>/var/nca/current</code>.</p> <p>The <code>logd_file_size</code> key specifies the value of the file size, in bytes, allowed for each log file specified in by the <code>logd_path_name</code> key. The default value is 1000000 bytes.</p> <p>In order to implement changes to the <code>ncaologd.conf</code> file, you will need to stop and start NCA logging or reboot.</p> <p>NCA stores logs in a binary format. Use the <code>ncab2clf(1)</code> utility to convert the log from a binary format to the Common Log File format.</p>		
EXAMPLES	<p>EXAMPLE 1 A Sample <code>ncaologd.conf</code> File</p> <p>The following is a sample <code>ncaologd.conf</code> file that specifies three log files:</p> <pre># # NCA Log Daemon Configuration File # status=disabled logd_path_name=/var/nca/log1 /var/nca/log2 /var/nca/log3 logd_file_size=1000000</pre> <p>Note that there is no NCA logging daemon. Logging is performed as one of the functions of the NCA software.</p>		
FILES	<table><tr><td>/etc/nca/ncaologd.conf</td><td>Lists configuration parameters for NCA logging.</td></tr></table>	/etc/nca/ncaologd.conf	Lists configuration parameters for NCA logging.
/etc/nca/ncaologd.conf	Lists configuration parameters for NCA logging.

ndpd.conf(4)

NAME	ndpd.conf – configuration file for IPv6 router autoconfiguration								
SYNOPSIS	/etc/inet/ndpd.conf								
DESCRIPTION	<p>The <code>ndpd.conf</code> file contains configuration information for <code>in.ndpd()</code>1M when used on a router. This file does not need to exist or can be empty on a host. The file has one configuration entry per line; note that lines can be extended with “\” followed by a newline. There are four forms of configuration entries which are identified by the first field on the line: <code>ifdefault</code>, <code>prefixdefault</code>, <code>if</code>, or <code>prefix</code>. The <code>ifdefault</code> and <code>if</code> entries set interface configuration variables; the former establishes the defaults for all interfaces. Any <code>ifdefault</code> entries must precede any <code>if</code> entries in the file.</p> <p>The <code>prefixdefault</code> and <code>prefix</code> entries control per-prefix configuration variables. <code>prefixdefault</code> establishes the defaults for all prefixes on all interfaces. Any <code>prefixdefault</code> entries must precede any <code>prefix</code> entries in the file.</p> <p>Each <code>ifdefault</code> entry is composed of a single line of the form:</p> <pre>ifdefault [if-variable-name value]*</pre> <p>Each <code>if</code> entry is composed of a single line of the form:</p> <pre>if interface [if-variable-name value]*</pre> <p>Each <code>prefixdefault</code> entry is composed of a single line of the form:</p> <pre>prefixdefault [prefix-variable-name value]*</pre> <p>Each <code>prefix</code> entry is composed of a single line of the form:</p> <pre>prefix prefix/prefix_length interface [prefix-variable-name value]*</pre> <p>Fields are separated by either SPACE or TAB characters. A ‘#’ (number sign) indicates the beginning of a comment. Characters up to the end of the line are not interpreted by routines that search this file.</p> <table><tr><td><code>interface</code></td><td>The name of a network interface, for example, <code>le0</code>.</td></tr><tr><td><code>prefix</code></td><td>An IPv6 address in standard hexadecimal notation, for example, <code>fec0:0:0:1::0</code>.</td></tr><tr><td><code>prefix_length</code></td><td>A number between 0 and 128.</td></tr><tr><td><code>if-variable-name</code></td><td>An interface variable as discussed in <i>RFC 2461</i> and <i>RFC 2462</i>. The following lists the each interface variable and its default value and unit:</td></tr></table>	<code>interface</code>	The name of a network interface, for example, <code>le0</code> .	<code>prefix</code>	An IPv6 address in standard hexadecimal notation, for example, <code>fec0:0:0:1::0</code> .	<code>prefix_length</code>	A number between 0 and 128.	<code>if-variable-name</code>	An interface variable as discussed in <i>RFC 2461</i> and <i>RFC 2462</i> . The following lists the each interface variable and its default value and unit:
<code>interface</code>	The name of a network interface, for example, <code>le0</code> .								
<code>prefix</code>	An IPv6 address in standard hexadecimal notation, for example, <code>fec0:0:0:1::0</code> .								
<code>prefix_length</code>	A number between 0 and 128.								
<code>if-variable-name</code>	An interface variable as discussed in <i>RFC 2461</i> and <i>RFC 2462</i> . The following lists the each interface variable and its default value and unit:								

Variable Name	Default	Unit
DupAddrDetectTransmits	1	Counter
AdvSendAdvertisements	false	Boolean
MaxRtrAdvInterval	600	Seconds
MinRtrAdvInterval	200	Seconds
AdvManagedFlag	false	Boolean
AdvOtherConfigFlag	false	Boolean
AdvLinkMTU	0	Bytes
AdvReachableTime	0	Milliseconds
AdvRetransTimer	0	Milliseconds
AdvCurHopLimit	0	Counter
AdvDefaultLifetime	1800	Seconds

prefix-variable-name

A prefix variable as discussed in *RFC 2461* and *RFC 2462*. The following lists the each interface variable and its default value and unit:

Variable Name	Default	Unit
AdvValidLifetime	2592000	Seconds
AdvOnLinkFlag	true	Boolean
AdvPreferredLifetime	604800	Seconds
AdvAutonomousFlag	true	Boolean
AdvValidExpiration	not set	Date/Time
AdvPreferredExpiration	not set	Date/Time

The "Expiration" variables are used to specify that the lifetime should be decremented in real time as specified in *RFC 2461*. If an "Expiration" variable is set then it takes precedence over the corresponding "Lifetime" variable setting.

value

The value is a function of the unit. Boolean values are true, false, on, off, 1, or 0.

Values in seconds can have characters appended for day (d), hour (h), minute (m) and second (s). The

ndpd.conf(4)

default is seconds. For example, 1h means 1 hour. This is equivalent to the value 3600.

Values in milliseconds can have characters appended for day (d), hour (h), minute (m) second (s), and millisecond (ms). The default is milliseconds. For example, 1h is equivalent to the value 3600000.

Date/time values are strings that use the recommended ISO date format described as "%Y-%m-%d %R", which represents a 4 digit year, a dash character, a numeric month, a dash character, and a numeric day of the month, followed by one or more whitespace characters and finally a 24 hour clock with hours, a colon, and minutes. For example, 1999-01-31 20:00 means 8pm January 31 in 1999. Since the date/time values contain a space, use single or double quotes to declare the value. For example:

```
prefixdefault AdvPreferredExpiration '1999-01-31 20:00'
```

EXAMPLES **EXAMPLE 1** Sending Router Advertisements for all Interfaces

The following example can be used to send router advertisements out to all interfaces:

```
# Send router advertisements out all interfaces
ifdefault AdvSendAdvertisements on
prefixdefault AdvOnLinkFlag on AdvAutonomousFlag on

# Advertise a (bogus) global prefix and a site
# local prefix on three interfaces using the default lifetimes
prefix 2:0:0:9255::0/64       hme0
prefix fec0:0:0:9255::0/64   hme0

prefix 2:0:0:9256::0/64       hme1
prefix fec0:0:0:9256::0/64   hme1

prefix 2:0:0:9259::0/64       hme2
prefix fec0:0:0:9259::0/64   hme2
```

netconfig(4)

NAME	netconfig – network configuration database						
SYNOPSIS	<code>/etc/netconfig</code>						
DESCRIPTION	<p>The network configuration database, <code>/etc/netconfig</code>, is a system file used to store information about networks that are connected to the system. The <code>netconfig</code> database and the routines that access it (see <code>getnetconfig(3NSL)</code>) are part of the Network Selection component. The Network Selection component also includes <code>getnetpath(3NSL)</code> routines to provide application-specific network search paths. These routines access the <code>netconfig</code> database based on the environment variable <code>NETPATH</code>. See <code>environ(5)</code>.</p> <p><code>netconfig</code> contains an entry for each network available on the system. Entries are separated by newlines. Fields are separated by whitespace and occur in the order in which they are described below. Whitespace can be embedded as “<code>\blank</code>” or “<code>\tab</code>”. Backslashes may be embedded as “<code>\\</code>”. Lines in <code>/etc/netconfig</code> that begin with a # (hash) in column 1 are treated as comments.</p> <p>Each of the valid lines in the <code>netconfig</code> database correspond to an available transport. Each entry is of the form:</p> <pre><i>network ID semantics flag protocol-family protocol-name \</i> <i>network-device translation-libraries</i></pre> <p><i>network ID</i> A string used to uniquely identify a network. <i>network ID</i> consists of non-null characters, and has a length of at least 1. No maximum length is specified. This namespace is locally significant and the local system administrator is the naming authority. All <i>network IDs</i> on a system must be unique.</p> <p><i>semantics</i> The <i>semantics</i> field is a string identifying the “semantics” of the network, that is, the set of services it supports, by identifying the service interface it provides. The <i>semantics</i> field is mandatory. The following semantics are recognized.</p> <table><tr><td><code>tpi_clts</code></td><td>Transport Provider Interface, connectionless</td></tr><tr><td><code>tpi_cots</code></td><td>Transport Provider Interface, connection oriented</td></tr><tr><td><code>tpi_cots_ord</code></td><td>Transport Provider Interface, connection oriented, supports orderly release.</td></tr></table> <p><i>flag</i> The <i>flag</i> field records certain two-valued (“true” and “false”) attributes of networks. <i>flag</i> is a string composed of a combination of characters, each of which indicates the value of the corresponding</p>	<code>tpi_clts</code>	Transport Provider Interface, connectionless	<code>tpi_cots</code>	Transport Provider Interface, connection oriented	<code>tpi_cots_ord</code>	Transport Provider Interface, connection oriented, supports orderly release.
<code>tpi_clts</code>	Transport Provider Interface, connectionless						
<code>tpi_cots</code>	Transport Provider Interface, connection oriented						
<code>tpi_cots_ord</code>	Transport Provider Interface, connection oriented, supports orderly release.						

attribute. If the character is present, the attribute is "true." If the character is absent, the attribute is "false." "-" indicates that none of the attributes are present.

Only one character is currently recognized:

v	Visible ("default") network. Used when the environment variable NETPATH is unset.
---	-----------------------------------------------------------------------------------

protocol family

The *protocol family* and *protocol name* fields are provided for protocol-specific applications. The *protocol family* field contains a string that identifies a protocol family. The *protocol family* identifier follows the same rules as those for *network IDs*; the string consists of non-null characters, it has a length of at least 1, and there is no maximum length specified. A "-" in the *protocol family* field indicates that no protocol family identifier applies (the network is experimental). The following are examples:

loopback	Loopback (local to host).
inet	Internetwork: UDP, TCP, and the like.
inet6	Internetwork over IPv6: UDP, TCP, and the like.
implink	ARPANET imp addresses
pup	PUP protocols: for example, BSP
chaos	MIT CHAOS protocols
ns	XEROX NS protocols
nbs	NBS protocols
ecma	European Computer Manufacturers Association
datakit	DATAKIT protocols
ccitt	CCITT protocols, X.25, and the like.
sna	IBM SNA
decnet	DECNET
dli	Direct data link interface
lat	LAT
hylink	NSC Hyperchannel
appletalk	Apple Talk

netconfig(4)

	<code>nit</code>	Network Interface Tap
	<code>ieee802</code>	IEEE 802.2; also ISO 8802
	<code>osi</code>	Umbrella for all families used by OSI (for example, <code>protosw</code> lookup)
	<code>x25</code>	CCITT X.25 in particular
	<code>osinet</code>	AFI = 47, IDI = 4
	<code>gosip</code>	U.S. Government OSI
<i>protocol name</i>		The <i>protocol name</i> field contains a string that identifies a protocol. The <i>protocol name</i> identifier follows the same rules as those for <i>network IDs</i> ; that is, the string consists of non-NULL characters, it has a length of at least 1, and there is no maximum length specified. A “-” indicates that none of the names listed apply. The following protocol names are recognized.
	<code>tcp</code>	Transmission Control Protocol
	<code>udp</code>	User Datagram Protocol
	<code>icmp</code>	Internet Control Message Protocol
<i>network device</i>		The <i>network device</i> is the full pathname of the device used to connect to the transport provider. Typically, this device will be in the <code>/dev</code> directory. The <i>network device</i> must be specified.
<i>translation libraries</i>		The <i>name-to-address translation libraries</i> support a “directory service” (a name-to-address mapping service) for the network. A “-” in this field indicates the absence of any <i>translation libraries</i> . This has a special meaning for networks of the protocol family <code>inet</code> : its name-to-address mapping is provided by the name service switch based on the entries for <code>hosts</code> and <code>services</code> in <code>nsswitch.conf(4)</code> . For networks of other families, a “-” indicates non-functional name-to-address mapping. Otherwise, this field consists of a comma-separated list of pathnames to dynamically linked libraries. The pathname of the library can be either absolute or relative. See <code>dlopen(3DL)</code> .
Each field corresponds to an element in the <code>struct netconfig</code> structure. <code>struct netconfig</code> and the identifiers described on this manual page are defined in <code><netconfig.h></code> . This structure includes the following members:		
	<code>char *nc_netid</code>	Network ID, including NULL terminator.

```

unsigned long nc_semantics
    Semantics.

unsigned long nc_flag
    Flags.

char *nc_protofmly
    Protocol family.

char *nc_proto
    Protocol name.

char *nc_device
    Full pathname of the network device.

unsigned long nc_nlookups
    Number of directory lookup libraries.

char **nc_lookups
    Names of the name-to-address translation libraries.

unsigned long nc_unused[9]
    Reserved for future expansion.

```

The *nc_semantics* field takes the following values, corresponding to the semantics identified above:

```

NC_TPI_CLTS
NC_TPI_COTS
NC_TPI_COTS_ORD

```

The *nc_flag* field is a bitfield. The following bit, corresponding to the attribute identified above, is currently recognized. NC_NOFLAG indicates the absence of any attributes.

```

NC_VISIBLE

```

EXAMPLES **EXAMPLE 1** A Sample netconfig File

Below is a sample netconfig file:

```

#
# The "Network Configuration" File.
#
# Each entry is of the form:
#
# <networkid> <semantics> <flags> <protofamily> <protoname><device> \
#     <nametoaddrlibs>
#
# The "-" in <nametoaddrlibs> for inet family transports indicates
# redirection to the name service switch policies for "hosts" and
# "services". The "-" may be replaced by nametoaddr libraries that

```

netconfig(4)

EXAMPLE 1 A Sample netconfig File (Continued)

```
# comply with the SVr4 specs, in which case the name service switch
# will not be used for netdirgetbyname, netdirgetbyaddr,
# gethostbyname, gethostbyaddr, getservbyname, and getservbyport.
# There are no nametoaddrlibs for the inet family in Solaris anymore.
#
#
# The following two entries starting with udp6 and tcp6 are meant to be
# used for IPv6. If you have Ipv6 enabled on your machine then you can
# uncomment these two lines to enable RPC and NFS to use the Ipv6 stack.
# Consult your network administrator before uncommenting.
#
#udp6      tpi_clts      v      inet6  udp      /dev/udp6      -
#tcp6      tpi_cots_ord  v      inet6  tcp      /dev/tcp6      -

udp      tpiclts      v      inet    udp      /dev/udp      -
tcp      tpicotsord  v      inet    tcp      /dev/tcp      -
rawip    tpiraw          -      inet    -        /dev/rawip    -
ticlts   tpiclts        v      loopback -        /dev/ticlts   straddr.so
ticotsord tpicotsord     v      loopback -        /dev/ticotsord straddr.so
ticots   tpicots      v      loopback -        /dev/ticots   straddr.so
```

System Administration Guide: IP Services

NAME	netgroup – list of network groups
SYNOPSIS	<code>/etc/netgroup</code>
DESCRIPTION	<p>A <code>netgroup</code> defines a network-wide group of hosts and users. Use a <code>netgroup</code> to restrict access to shared NFS filesystems and to restrict remote login and shell access.</p> <p>Network groups are stored in one of the Network Information Services, either NIS or NIS+, not in a local file.</p> <p>This manual page describes the format for a file that may be used to supply input to the <code>makedbm(1M)</code> or <code>nissaddent(1M)</code> programs that are used to build the NIS map or NIS+ table, respectively.</p> <p>Each line of the file defines the name and membership of a network group. The line should have the format:</p> <p><code>groupname member . . .</code> The items on a line may be separated by a combination of one or more spaces or tabs.</p> <p>The <i>groupname</i> is the name of the group being defined. This is followed by a list of members of the group. Each <i>member</i> is either another group name, all of whose members are to be included in the group being defined, or a triple of the form:</p> <p><code>(hostname,username,domainname)</code></p> <p>In each triple, any of the three fields <i>hostname</i>, <i>username</i>, and <i>domainname</i>, can be empty. An empty field signifies a wildcard that matches any value in that field. Thus:</p> <p><code>everything (, ,this.domain)</code> defines a group named "everything" for the domain "this.domain" to which every host and user belongs.</p> <p>The <i>domainname</i> field refers to the domain in which the triple is valid, not the domain containing the host or user. In fact, applications using <code>netgroup</code> generally do not check the <i>domainname</i>. Therefore, using</p> <p><code>(, ,domain)</code> is equivalent to</p> <p><code>(, ,)</code> You can also use <code>netgroups</code> to control NFS mount access (see <code>share_nfs(1M)</code>) and to control remote login and shell access (see <code>hosts.equiv(4)</code>). You can also use them to control local login access (see <code>passwd(4)</code>, <code>shadow(4)</code>, and <code>compat</code> in <code>nsswitch.conf(4)</code>).</p> <p>When used for these purposes, a host is considered a member of a <code>netgroup</code> if the <code>netgroup</code> contains any triple in which the <i>hostname</i> field matches the name of the host requesting access and the <i>domainname</i> field matches the domain of the host controlling access.</p>

netgroup(4)

Similarly, a user is considered a member of a `netgroup` if the `netgroup` contains any triple in which the `username` field matches the name of the user requesting access and the `domainname` field matches the domain of the host controlling access.

Note that when `netgroups` are used to control NFS mount access, access is granted depending only on whether the requesting host is a member of the `netgroup`. Remote login and shell access can be controlled both on the basis of host and user membership in separate `netgroups`.

FILES `/etc/netgroup` used by `/var/yp/Makefile` on NIS masters to build the NIS `netgroup` map

Note that the `netgroup` information must always be stored in a network information service, either NIS or NIS+. The local file is only used to construct the `netgroup` NIS maps or NIS+ table; it is never consulted directly.

SEE ALSO `nis+(1)`, `makedbm(1M)`, `nisaddent(1M)`, `share_nfs(1M)`, `innetgr(3C)`, `hosts(4)`, `hosts.equiv(4)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`

NOTES `netgroup` requires NIS or NIS+.

Applications may make general membership tests using the `innetgr()` function. See `innetgr(3C)`.

Because the "-" character will not match any specific username or hostname, it is commonly used as a placeholder that will match only wildcarded membership queries. So, for example:

```
onlyhosts    (host1,-,our.domain) (host2,-,our.domain)
onlyusers    (-,john,our.domain) (-,linda,our.domain)
```

effectively define `netgroups` containing only hosts and only users, respectively. Any other string that is guaranteed not to be a legal username or hostname will also suffice for this purpose.

Use of placeholders will improve search performance.

When a machine with multiple interfaces and multiple names is defined as a member of a `netgroup`, one must list all of the names. See `hosts(4)`. A manageable way to do this is to define a `netgroup` containing all of the machine names. For example, for a host "gateway" that has names "gateway-subnet1" and "gateway-subnet2" one may define the `netgroup`:

```
gateway (gateway-subnet1, ,our.domain) (gateway-subnet2, ,our.domain)
```

and use this `netgroup` "gateway" whenever the host is to be included in another `netgroup`.

NAME	netid – netname database																		
SYNOPSIS	<code>/etc/netid</code>																		
DESCRIPTION	<p>The <code>netid</code> file is a local source of information on mappings between netnames (see <code>secure_rpc(3NSL)</code>) and user ids or hostnames in the local domain. The <code>netid</code> file can be used in conjunction with, or instead of, the network source: NIS or NIS+. The <code>publickey</code> entry in the <code>nsswitch.conf</code> (see <code>nsswitch.conf(4)</code>) file determines which of these sources will be queried by the system to translate netnames to local user ids or hostnames.</p> <p>Each entry in the <code>netid</code> file is a single line of the form:</p> <pre><i>netname uid:gid, gid, gid . . .</i></pre> <p>or</p> <pre><i>netname</i> 0:hostname</pre> <p>The first entry associates a local user id with a netname. The second entry associates a hostname with a netname.</p> <p>The <code>netid</code> file field descriptions are as follows:</p> <table> <tr> <td><i>netname</i></td> <td>The operating system independent network name for the user or host. <i>netname</i> has one of two formats. The format used to specify a host is of the form:</td> </tr> <tr> <td></td> <td><code>unix.hostname@domain</code></td> </tr> <tr> <td></td> <td>where <i>hostname</i> is the name of the host and <i>domain</i> is the network domain name.</td> </tr> <tr> <td></td> <td>The format used to specify a user id is of the form:</td> </tr> <tr> <td></td> <td><code>unix.uid@domain</code></td> </tr> <tr> <td></td> <td>where <i>uid</i> is the numerical id of the user and <i>domain</i> is the network domain name.</td> </tr> <tr> <td><i>uid</i></td> <td>The numerical id of the user (see <code>passwd(4)</code>). When specifying a host name, <i>uid</i> is always zero.</td> </tr> <tr> <td><i>group</i></td> <td>The numerical id of the group the user belongs to (see <code>group(4)</code>). Several groups, separated by commas, may be listed for a single <i>uid</i>.</td> </tr> <tr> <td><i>hostname</i></td> <td>The local hostname (see <code>hosts(4)</code>).</td> </tr> </table> <p>Blank lines are ignored. Any part of a line to the right of a '#' symbol is treated as a comment.</p>	<i>netname</i>	The operating system independent network name for the user or host. <i>netname</i> has one of two formats. The format used to specify a host is of the form:		<code>unix.hostname@domain</code>		where <i>hostname</i> is the name of the host and <i>domain</i> is the network domain name.		The format used to specify a user id is of the form:		<code>unix.uid@domain</code>		where <i>uid</i> is the numerical id of the user and <i>domain</i> is the network domain name.	<i>uid</i>	The numerical id of the user (see <code>passwd(4)</code>). When specifying a host name, <i>uid</i> is always zero.	<i>group</i>	The numerical id of the group the user belongs to (see <code>group(4)</code>). Several groups, separated by commas, may be listed for a single <i>uid</i> .	<i>hostname</i>	The local hostname (see <code>hosts(4)</code>).
<i>netname</i>	The operating system independent network name for the user or host. <i>netname</i> has one of two formats. The format used to specify a host is of the form:																		
	<code>unix.hostname@domain</code>																		
	where <i>hostname</i> is the name of the host and <i>domain</i> is the network domain name.																		
	The format used to specify a user id is of the form:																		
	<code>unix.uid@domain</code>																		
	where <i>uid</i> is the numerical id of the user and <i>domain</i> is the network domain name.																		
<i>uid</i>	The numerical id of the user (see <code>passwd(4)</code>). When specifying a host name, <i>uid</i> is always zero.																		
<i>group</i>	The numerical id of the group the user belongs to (see <code>group(4)</code>). Several groups, separated by commas, may be listed for a single <i>uid</i> .																		
<i>hostname</i>	The local hostname (see <code>hosts(4)</code>).																		

netid(4)

EXAMPLES | **EXAMPLE 1** A sample netid file.

Here is a sample netid file:

```
unix.789@West.Sun.COM      789:30,65
unix.123@Bldg_xy.Sun.COM   123:20,1521
unix.candlestick@campus1.bayarea.EDU  0:candlestick
```

NAME	netmasks – network mask database
SYNOPSIS	<code>/etc/inet/netmasks</code> <code>/etc/netmasks</code>
DESCRIPTION	<p>The <code>netmasks</code> file contains network masks used to implement IP subnetting. It supports both standard subnetting as specified in <i>RFC-950</i> and variable length subnetting as specified in <i>RFC-1519</i>. When using standard subnetting there should be a single line for each network that is subnetted in this file with the network number, any number of SPACE or TAB characters, and the network mask to use on that network. Network numbers and masks may be specified in the conventional IP ‘.’ (dot) notation (like IP host addresses, but with zeroes for the host part). For example,</p> <pre style="text-align: center;">128.32.0.0 255.255.255.0</pre> <p>can be used to specify that the Class B network 128.32.0.0 should have eight bits of subnet field and eight bits of host field, in addition to the standard sixteen bits in the network field.</p> <p>When using variable length subnetting, the format is identical. However, there should be a line for each subnet with the first field being the subnet and the second field being the netmask that applies to that subnet. The users of the database, such as <code>ifconfig(1M)</code>, perform a lookup to find the longest possible matching mask. It is possible to combine the <i>RFC-950</i> and <i>RFC-1519</i> form of subnet masks in the <code>netmasks</code> file. For example,</p> <pre style="text-align: center;">128.32.0.0 255.255.255.0 128.32.27.0 255.255.255.240 128.32.27.16 255.255.255.240 128.32.27.32 255.255.255.240 128.32.27.48 255.255.255.240 128.32.27.64 255.255.255.240 128.32.27.80 255.255.255.240 128.32.27.96 255.255.255.240 128.32.27.112 255.255.255.240 128.32.27.128 255.255.255.240 128.32.27.144 255.255.255.240 128.32.27.160 255.255.255.240 128.32.27.176 255.255.255.240 128.32.27.192 255.255.255.240 128.32.27.208 255.255.255.240 128.32.27.224 255.255.255.240 128.32.27.240 255.255.255.240 128.32.64.0 255.255.255.192</pre> <p>can be used to specify different netmasks in different parts of the 128.32.0.0 Class B network number. Addresses 128.32.27.0 through 128.32.27.255 have a subnet mask with 28 bits in the combined network and subnet fields (often referred to as the subnet field) and 4 bits in the host field. Furthermore, addresses 128.32.64.0 through 128.32.64.63 have a 26 bits in the subnet field. Finally, all other addresses in the range 128.32.0.0 through 128.32.255.255 have a 24 bit subnet field.</p>

netmasks(4)

Invalid entries are ignored.

NOTES `/etc/inet/netmasks` is the official SVr4 name of the netmasks file. The symbolic link `/etc/netmasks` exists for BSD compatibility.

NAME	netrc – file for ftp remote login data
DESCRIPTION	<p>The <code>.netrc</code> file contains data for logging in to a remote host over the network for file transfers by <code>ftp(1)</code>. This file resides in the user's home directory on the machine initiating the file transfer. Its permissions should be set to disallow read access by group and others (see <code>chmod(1)</code>).</p> <p>The following tokens are recognized; they may be separated by SPACE, TAB, or NEWLINE characters:</p> <p><code>machine name</code> Identify a remote machine name. The auto-login process searches the <code>.netrc</code> file for a <code>machine</code> token that matches the remote machine specified on the <code>ftp</code> command line or as an open command argument. Once a match is made, the subsequent <code>.netrc</code> tokens are processed, stopping when the EOF is reached or another <code>machine</code> token is encountered.</p> <p><code>default</code> Same as <code>machine name</code>, except that <code>default</code> matches any name. There can be only one <code>default</code> token, and it must be after all <code>machine</code> tokens. The <code>default</code> token is normally used as follows:</p> <pre>default login anonymous password user@site</pre> <p>Such an entry gives the user automatic anonymous <code>ftp</code> login to machines not specified in <code>.netrc</code>.</p> <p><code>login name</code> Identify a user on the remote machine. If this token is present, the auto-login process will initiate a login using the specified name.</p> <p><code>password string</code> Supply a password. If this token is present, the auto-login process will supply the specified string if the remote server requires a password as part of the login process. Note: if this token is present in the <code>.netrc</code> file, <code>ftp</code> will abort the auto-login process if the <code>.netrc</code> is readable by anyone besides the user.</p> <p><code>account string</code> Supply an additional account password. If this token is present, the auto-login process supplies the specified string if the remote server requires an additional account password. If the remote server does not require an additional account password, the auto-login process will initiate an <code>ACCT</code> command.</p> <p><code>macdef name</code> Define a macro. This token functions the same as <code>ftp macdef</code>. A macro is defined with the specified name; its contents begin with the next <code>.netrc</code> line and continue until a null line (consecutive NEWLINE characters) is encountered. If a macro named <code>init</code> is defined, it is automatically executed as the last step in the auto-login process.</p>
EXAMPLES	<p>EXAMPLE 1 A Sample <code>.netrc</code> File</p> <p>A <code>.netrc</code> file containing the following line:</p>

netrc(4)

EXAMPLE 1 A Sample .netrc File *(Continued)*

```
machine ray login demo password mypassword
allows an autologin to the machine ray using the login name demo with password
mypassword.
```

FILES ~/.netrc

SEE ALSO chmod(1), ftp(1), in.ftpd(1M)

NAME	networks – network name database
SYNOPSIS	<code>/etc/inet/networks</code> <code>/etc/networks</code>
DESCRIPTION	<p>The <code>networks</code> file is a local source of information regarding the networks which comprise the Internet. The <code>networks</code> file can be used in conjunction with, or instead of, other networks sources, including the NIS maps <code>networks.byname</code> and <code>networks.byaddr</code> and the NIS+ table <code>networks</code>. Programs use the <code>getnetbyname(3SOCKET)</code> routines to access this information.</p> <p>The network file has a single line for each network, with the following information:</p> <p><i>official-network-name network-number aliases</i></p> <p>Items are separated by any number of SPACE and/or TAB characters. A '#' indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file. This file is normally created from the official network database maintained at the Network Information Control Center (NIC), though local changes may be required to bring it up to date regarding unofficial aliases and/or unknown networks.</p> <p>Network numbers may be specified in the conventional dot ('.') notation using the <code>inet_network</code> routine from the Internet address manipulation library, <code>inet(7P)</code>. Network names may contain any printable character other than a field delimiter, NEWLINE, or comment character.</p>
SEE ALSO	<code>getnetbyaddr(3SOCKET)</code> , <code>getnetbyname(3SOCKET)</code> , <code>inet(3SOCKET)</code> , <code>nsswitch.conf(4)</code> , <code>inet(7P)</code>
NOTES	<p>The official SVR4 name of the <code>networks</code> file is <code>/etc/inet/networks</code>. The symbolic link <code>/etc/networks</code> exists for BSD compatibility.</p> <p>The network database does not support subnet masks in general, so <code>getnetbyaddr(3SOCKET)</code> cannot differentiate between networks of 11.128.0.0/255.192.0.0 and 11.128.0.0/255.240.0.0.</p>

nfslog.conf(4)

NAME	nfslog.conf – NFS server logging configuration file
SYNOPSIS	/etc/nfs/nfslog.conf
DESCRIPTION	<p>The <code>nfslog.conf</code> file specifies the location of the NFS server logs, as well as the location of the private work files used by the NFS server and <code>nfslogd(1M)</code> daemon during logging. Each entry in the file consists of a mandatory tag identifier and one or more parameter identifiers. The parameter identifier specifies the value or location of the specific parameter. For instance, the parameter identifier <code>"log=/var/nfs/logs/serverLog"</code> specifies the location of the NFS server activity log. The mandatory tag identifier serves as an index into the <code>/etc/nfs/nfslog.conf</code> file to identify the various parameters to be used. At export time, the <code>share_nfs(1M)</code> command specifies the NFS server logging parameters to use by associating a tag from the <code>/etc/nfs/nfslog.conf</code> file to the exported file system. It is legal for more than one file system to be exported using the same logging tag identifier.</p> <p>A "global" tag identifier is included in <code>/etc/nfs/nfslog.conf</code>. It specifies the default set of values to be used during logging. If no tag identifier is specified at export time, then the values in the "global" entry are used. The "global" values can be modified by updating this entry in <code>/etc/nfs/nfslog.conf</code>.</p> <p>Each entry in the file must contain a mandatory tag identifier and at least one parameter/value pair. If a parameter is not specified in a given entry, the global value of the parameter will be used. The exact entry syntax follows:</p> <pre><tag> [defaultdir=<path>] [log=<path><file>] [fhtable=<path><file>] \ [buffer=<path><file>] [logformat=basic extended]</pre> <p><code>defaultdir=<path></code> Specifies the directory where the logging files and working files will be placed. This path is prepended to all relative paths specified in other parameters.</p> <p><code>log=<path><file></code> Specifies the location of the user-readable log file. The log will be located in the <code>defaultdir</code>, unless <code><path></code> is an absolute path.</p> <p><code>fhtable=<path><file></code> Specifies the location of the private file handle to path mapping database files. These database files are for the private use of the NFS server kernel module and the <code>nfslogd</code> daemon. These files will be located in the <code>defaultdir</code>, unless <code><path></code> is an absolute path. These database files are permanently stored in the file system. Consult <code>nfslogd(1M)</code> for information on pruning the database files.</p>

<code>buffer=<path><file></code>	Specifies the location of the private work buffer file used by the NFS server kernel module to record raw RPC information. This file is later processed by the <code>nfslog</code> daemon, which in turn generates the user-readable log file. This work buffer file will be located in the <code>defaultdir</code> , unless <code><path></code> is an absolute path.
<code>logformat=basic extended</code>	Sets the format of the user-readable log file. If not specified, the basic format is used. The basic format is compatible with log files generated by the Washington University FTPd. The extended format provides a more detailed log, which includes directory modification operations not included in the basic format, such as <code>mkdir</code> , <code>rmdir</code> and <code>remove</code> . Note that the extended format is not compatible with Washington University's FTPd log format.

EXAMPLES **EXAMPLE 1** Using the `global` Tag

The "global" tag may be modified so that all exported file systems that enabled logging use a common set of parameters that conform to the specific needs of the user. These values are used until a specific tag identifier overrides them.

```
global    defaultdir=/var/nfs log=logs/nfslog \
          fhstable=tables/fhtable buffer=buffers/nfslog_workbuffer \
          logformat=basic
```

EXAMPLE 2 Overriding the Global `defaultdir` and `logformat`

Because log files can become very large, it may be desirable to store the logs and working files in separate file systems. This can be easily accomplished by simply specifying a different `defaultdir` for every file system exported by means of a unique tag:

```
engineering    defaultdir=/engineering/logging \
                logformat=extended
accounting     defaultdir=/accounting/logging
marketing      defaultdir=/marketing/logging
```

File systems shared with the engineering identifier will have their logs and workfiles located in `/engineering/logging`. For instance, the log file will be located at `/engineering/logging/logs/nfslog`. Note that the engineering log file will be stored in the extended format, while the rest of the log files will remain in the basic format.

Any of the parameters can be updated in a tag identifier, which overrides the global settings.

nfslog.conf(4)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssr

SEE ALSO `nfslogd(1M)`, `share_nfs(1M)`, `attributes(5)`

NOTES Logs, work files, and file handle to path mapping database can become very large. Be aware of appropriate placement within the file system name space. See `nfslogd(1M)` for information on pruning the database files and cycling logs.

NAME	nisfiles – NIS+ database files and directory structure										
SYNOPSIS	<code>/var/nis</code>										
DESCRIPTION	<p>The Network Information Service Plus (NIS+) uses a memory based, replicated database. This database uses a set of files in the <code>/var/nis</code> directory for checkpointing to table storage and for maintaining a transaction log. Additionally, the NIS+ server and client use files in this directory to store binding and state information.</p> <p>The NIS+ service implements an authentication and authorization system that is built upon Secure RPC. In this implementation, the service uses a table named <code>cred.org_dir.domain-name</code> to store the public and private keys of principals that are authorized to access the NIS+ namespace. It stores group access information in the subdomain <code>groups_dir.domain-name</code> as <i>group</i> objects. These two tables appear as files in the <code>/var/nis/data</code> directory on the NIS+ server.</p> <p>Unlike the previous versions of the network information service, in NIS+, the information in the tables is initially loaded into the service from the ASCII files on the server and then updated using NIS+ utilities (see <code>nistbladm(1)</code>). Some sites may wish to periodically regenerate the ASCII files for archival purposes. To do this, a script should be added in the <code>crontab(1)</code> of the server that lists these tables and creates the ASCII file from the result.</p> <p>Note that except for the <code>NIS_COLDSTART</code> and <code>NIS_SHARED_DIRCACHE</code> file, no other files should be manipulated by commands such as <code>cp(1)</code>, <code>mv(1)</code> or <code>rm(1)</code>. The transaction log file keeps logs of all changes made, and hence the files cannot be manipulated independently.</p> <p>The files described below are stored in the <code>/var/nis</code> directory:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>NIS_COLDSTART</code></td> <td>Contains NIS+ directory objects that are to be preloaded into the NIS+ cache at startup time. This file is usually created at NIS+ installation time. See <code>nisinit(1M)</code> or <code>nisclient(1M)</code>.</td> </tr> <tr> <td style="vertical-align: top;"><code>NIS_SHARED_DIRCACHE</code></td> <td>Contains the current cache of NIS+ bindings being maintained by the cache manager. The contents can be viewed with <code>nisshowcache(1M)</code>.</td> </tr> <tr> <td style="vertical-align: top;"><code>client_info</code></td> <td>Contains configuration information (preferred servers, options, etc.) for <code>nis_cachemgr(1M)</code> and (potentially) other NIS+ clients on the system. It is manipulated by the <code>nisprefadm(1M)</code> command.</td> </tr> <tr> <td style="vertical-align: top;"><code>.pref_servers</code></td> <td>A cached copy of preferred server information. It is maintained by <code>nis_cachemgr</code>. Do not edit this file manually.</td> </tr> <tr> <td style="vertical-align: top;"><code>trans.log</code></td> <td>Contains a transaction log that is maintained by the NIS+ service. It can be viewed using the <code>nislog(1M)</code> command. This file contains holes. Its apparent size</td> </tr> </table>	<code>NIS_COLDSTART</code>	Contains NIS+ directory objects that are to be preloaded into the NIS+ cache at startup time. This file is usually created at NIS+ installation time. See <code>nisinit(1M)</code> or <code>nisclient(1M)</code> .	<code>NIS_SHARED_DIRCACHE</code>	Contains the current cache of NIS+ bindings being maintained by the cache manager. The contents can be viewed with <code>nisshowcache(1M)</code> .	<code>client_info</code>	Contains configuration information (preferred servers, options, etc.) for <code>nis_cachemgr(1M)</code> and (potentially) other NIS+ clients on the system. It is manipulated by the <code>nisprefadm(1M)</code> command.	<code>.pref_servers</code>	A cached copy of preferred server information. It is maintained by <code>nis_cachemgr</code> . Do not edit this file manually.	<code>trans.log</code>	Contains a transaction log that is maintained by the NIS+ service. It can be viewed using the <code>nislog(1M)</code> command. This file contains holes. Its apparent size
<code>NIS_COLDSTART</code>	Contains NIS+ directory objects that are to be preloaded into the NIS+ cache at startup time. This file is usually created at NIS+ installation time. See <code>nisinit(1M)</code> or <code>nisclient(1M)</code> .										
<code>NIS_SHARED_DIRCACHE</code>	Contains the current cache of NIS+ bindings being maintained by the cache manager. The contents can be viewed with <code>nisshowcache(1M)</code> .										
<code>client_info</code>	Contains configuration information (preferred servers, options, etc.) for <code>nis_cachemgr(1M)</code> and (potentially) other NIS+ clients on the system. It is manipulated by the <code>nisprefadm(1M)</code> command.										
<code>.pref_servers</code>	A cached copy of preferred server information. It is maintained by <code>nis_cachemgr</code> . Do not edit this file manually.										
<code>trans.log</code>	Contains a transaction log that is maintained by the NIS+ service. It can be viewed using the <code>nislog(1M)</code> command. This file contains holes. Its apparent size										

nisfiles(4)

	may be a lot higher than its actual size. There is only one transaction log per server.
<code>data.dict</code>	A dictionary that is used by the NIS+ database to locate its files. It is created by the default NIS+ database package.
<code>data.dict.log</code>	The log file for the database dictionary. When the server is checkpointed (see the <code>-C</code> option of <code>nisping(1M)</code>), this file will be deleted.
<code>data</code>	Contains databases that the server uses.
<code>data/root.object</code>	On root servers, this file contains a directory object that describes the root of the name space.
<code>data/parent.object</code>	On root servers, this file contains a directory object that describes the parent namespace. This file is created by the <code>nisinit(1M)</code> command.
<code>data/table_name</code>	For each table in the directory there is a file with the same name that stores the information about that table. If there are subdirectories within this directory, the database for the table is stored in the file, <code>table_name.subdirectory</code> .
<code>data/table_name.log</code>	Contains the database log for the table <code>table_name</code> . The log file maintains the state of individual transactions to each database. When a database has been checkpointed (that is, all changes have been made to the <code>data/table_name</code> stable storage), this log file will be deleted.
	Currently, NIS+ does not automatically do checkpointing. The system administrator may want to do <code>nisping-C</code> operations periodically (such as, once a day) to checkpoint the log file. This can be done either through a <code>cron(1M)</code> job, or manually.
<code>data/root_dir</code>	On root servers, this file stores the database associated with the root directory. It is similar to other table databases. The corresponding log file is called <code>root_dir.log</code> .
<code>data/cred.org_dir</code>	Table containing the credentials of principals in this NIS+ domain.
<code>data/groups_dir</code>	Table containing the group authorization objects needed by NIS+ to authorize group access.
<code>data/serving_list</code>	Contains a list of all NIS+ directories that are being served by the NIS+ server on this server. When this

nisfiles(4)

server is added or deleted from any NIS+ directory object, this file is updated by the server.

SEE ALSO cp(1), crontab(1), mv(1), nis(1), nis_cachemgr(1M), niscat(1), nismatch(1), nistbladm(1), rm(1), cron(1M), nisclient(1M), nisinit(1M), nislog(1M), nisping(1M), nisprefadm(1M), nisshowcache(1M), nis_objects(3NSL)

NIS+LDAPmapping(4)

NAME	NIS+LDAPmapping – configuration file for mapping between NIS+ and LDAP
SYNOPSIS	<code>/var/nis/NIS+LDAPmapping</code>
DESCRIPTION	<p>The <code>/var/nis/NIS+LDAPmapping</code> configuration file specifies information for connecting to an LDAP server. It also contains the mapping between NIS+ objects, particularly table entries, and attributes. This information can come from LDAP, from this file, from the <code>rpc.nisd(1M)</code> command line, or from a combination of all three. The values in this file supersede those obtained from the LDAP server, but values from the command line supersede those in the file.</p> <p>Each line in the file can be up to 8191 bytes long, not counting the newline. There can be an indefinite number of continuation lines. A continuation is indicated by a <code>'\'</code> (backslash) in the last position, immediately before the newline of a line. Characters are escaped, that is, exempted from special interpretation, when preceded by a backslash character.</p> <p>The <code>'#'</code> (hash) character starts a comment. White space is either ASCII space or a horizontal tab. In general, lines consist of optional white space, an attribute name, at least one white space character, and an attribute value.</p>
Getting Started	<p>The default <code>rpc.nisd(4)</code> configuration file at <code>/etc/default/rpc.nisd</code> and the template file at <code>/var/nis/NIS+LDAPmapping.template</code> are sufficient for the minimum NIS+ installation. The following assumptions are made:</p> <ol style="list-style-type: none">1. The NIS+ standard directories, tables, and groups created by <code>nissetup(1M)</code> or <code>nissserver(1M)</code> should be mapped. However, the <code>timezone.org_dir</code> and <code>client_info.org_dir</code> tables should not be mapped.2. The NIS+ objects for which the <code>rpc.nisd</code> is a master are mapped both to and from LDAP.3. Those NIS+ objects for which the <code>rpc.nisd</code> is a replica are mapped from LDAP.4. The LDAP server is running on the local machine, and it can be reached at port 389 on the <code>127.0.0.1</code> IP address.5. The authentication method is <code>none</code>, meaning that all LDAP calls, whether for reading or writing, are unauthenticated. There is no transport layer security.6. The default values for TTLs and LDAP container locations and object classes are valid.7. The LDAP server supports <i>RFC 2307bis</i>. You want to use the <i>RFC 2307bis</i> object classes and attributes. See NOTES8. The <code>nisplusObject</code> attribute, the <code>nisplusObjectContainer</code> object class, and the <code>ou=nisPlus</code> container have been created.9. You do not need to store or retrieve table entry owner, group owner, entry access rights, or entry object TTL in or from LDAP. For more information on these pseudo-columns, see the discussion of <code>zo_owner</code>, and the like, in the description of the <code>nisplusLDAPcolumnFromAttribute</code> attribute.

10. NIS+ principal names and RPC netnames (the `cname` and `auth_name` columns, respectively, in the `cred.org_dir` table) should be derived from the owner of the `cred` table. For example, if the owner is `npadm.my.dom.ain.`, the `cname` and `auth_name` values for entries created from LDAP data will be of the form:

```
user-or-host.my.dom.ain.
```

and

```
unix.uid-or-host@my.dom.ain
```

respectively.

If these assumptions are true, you can enable mapping by copying the `/var/nis/NIS+LDAPmapping.template` file to `/var/nis/NIS+LDAPmapping` and restart the `rpc.nisd`. If you want to either upload NIS+ data to LDAP, or download LDAP data to NIS+, see the description of the `nisplusLDAPinitialUpdateAction` attribute on `rpc.nisd(4)`.

If one or more of the assumptions are false, do the following:

1. To remove mappings, identify the database id of the NIS+ object that should not be mapped, then delete or comment out the `nisplusLDAPdatabaseIdMapping`, `nisplusLDAPentryTtl`, `nisplusLDAPobjectDN`, `nisplusLDAPattributeFromColumn`, and `nisplusLDAPcolumnFromAttribute` attributes for that database id.

To add mappings, find an existing mapping for a NIS+ object similar to the one you want to map, and then use that mapping as a template to create the `nisplusLDAPdatabaseIdMapping`, `nisplusLDAPentryTtl`, `nisplusLDAPobjectDN`, `nisplusLDAPattributeFromColumn`, and `nisplusLDAPcolumnFromAttribute` attributes for the new mapping. The new mapping must have a unique database id.

To enable mapping of the `timezone` or `client_info` tables, consult your LDAP server documentation about how to create attributes and object classes, and set up the following. The following is LDIF data for `ldapadd(1)`. Attribute and object class OIDs are examples only.

For `client_info`:

```
dn: cn=schema
changetype: modify
add: attributetypes
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.12.0 \
    NAME 'nisplusClientInfoAttr' \
    DESC 'NIS+ client_info table client column' \
    SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 SINGLE-VALUE )
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.12.1 \
    NAME 'nisplusClientInfoInfo' \
    DESC 'NIS+ client_info table info column' \
    SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 SINGLE-VALUE )
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.12.2 \
    NAME 'nisplusClientInfoFlags' \
```

NIS+LDAPmapping(4)

```
DESC 'NIS+ client_info table flags column' \  
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 SINGLE-VALUE )
```

```
dn: cn=schema  
changetype: modify  
add: objectclasses  
objectclasses: ( 1.3.6.1.4.1.42.2.27.5.42.42.13.0 \  
    NAME 'nisplusClientInfoData' \  
    DESC 'NIS+ client_info table data' \  
    SUP top STRUCTURAL MUST ( cn ) \  
    MAY ( nisplusClientInfoAttr $ nisplusClientInfoInfo $ nisplusClientInfoFlags))
```

For the ou=ClientInfo container, substitute your actual search base for *searchBase*):

```
dn: ou=ClientInfo,searchBase  
ou: ClientInfo  
objectClass: top  
objectClass: organizationalUnit
```

For timezone:

```
dn: cn=schema  
changetype: modify  
add: attributetypes  
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.15.0 NAME 'nisplusTimeZone' \  
    DESC 'tzone column from NIS+ timezone table' \  
    SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 SINGLE-VALUE )
```

```
dn: cn=schema  
changetype: modify  
add: objectclasses  
objectclasses: ( 1.3.6.1.4.1.42.2.27.5.42.42.16.0 NAME 'nisplusTimeZoneData' \  
    DESC 'NIS+ timezone table data' \  
    SUP top STRUCTURAL MUST ( cn ) \  
    MAY ( nisplusTimeZone $ description ) )
```

For the ou=Timezone container:

```
dn: ou=Timezone,searchBase  
ou: Timezone  
objectClass: top  
objectClass: organizationalUnit
```

Uncomment the mapping attributes for `timezone` and `client_info` in the mapping file, and restart the `rpc.nisd(1M)` daemon.

2. To disable write mapping, edit the `nisplusLDAPObjectDN` value for the appropriate database id,. Remove the `writeObjectSpec` value, leaving only the `readObjectSpec` value. Make sure there are no trailing colons.

To disable read mapping, remove the `readObjectSpec`, leaving the database id, two colons, and the `writeObjectSpec` value.

3. Replicas cannot write-map objects. Remove mapping entirely for the database ids as described above.

4. Change the `preferredServerList` value to the correct server address(es) and port(s). If configuration data is retrieved from LDAP, also edit the `nisplusLDAPpreferredServerList` value.
5. Edit the `authenticationMethod` attribute value to the authentication method that you want to use. If configuration data is retrieved from LDAP, edit the `nisplusLDAPconfigAuthenticationMethod` value. If the method is anything other than none, you will need to specify one or more of the following, depending upon the method.

```
nisplusLDAPconfigProxyUser
```

```
nisplusLDAPproxyUser
```

The `/nisplusbind-DN` to use for authentication.

```
nisplusLDAPconfigProxyPassword
```

```
nisplusLDAPproxyPassword
```

The password or key for the bind-DN and method. Make sure that the file containing the password or key is protected from access by unauthorized users.

To use transport layer security, set `nisplusLDAPconfigTLS` or `nisplusLDAPTLS` to `ssl`, and set `nisplusLDAPconfigTLSCertificateDBPath` or `nisplusLDAPTLSCertificateDBPath` to the file containing the certificate DB. In order to successfully use authentication and transport layer security, the server must also support the chosen values.

6. To change the TTLs, edit the `nisplusLDAPentryTtl` for the appropriate database id.
To change LDAP container locations or object classes, edit the `nisplusLDAPobjectDN` value for the appropriate database id.
7. To determine which object classes and attributes are supported, see *System Administration Guide: Naming and Directory Services*. If you are using the iPlanet directory server, see `idsconfig(1M)`
8. Refer to your LDAP server documentation for how to create attributes and object classes, and set up the following:

```
dn: cn=schema
changetype: modify
add: attributetypes
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.1.0 NAME 'nisplusObject' \
DESC 'An opaque representation of a NIS+ object' \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.5 SINGLE-VALUE )
```

```
dn: cn=schema
changetype: modify
add: objectclasses
objectclasses: ( 1.3.6.1.4.1.42.2.27.5.42.42.2.0 NAME 'nisplusObjectContainer' \
SUP top STRUCTURAL DESC 'Abstraction of a NIS+ object' \
MUST ( cn $ nisplusObject )
object).
```

NIS+LDAPmapping(4)

ou=nisPlus is a container assumed to reside at the defaultSearchBase. See rpc.nisd(4). The following LDIF input to ldapadd(1) will create the ou=nisPlus container. Replace dc=some, dc=domain with your actual base.

```
dn: ou=nisPlus,dc=some,dc=domain
ou: nisPlus
objectClass: top
objectClass: organizationalUnit
```

The nisplusObjectContainer, nisplusObject, and ou=nisPlus labels are suggestions. If you change nisplusObjectContainer, or ou=nisPlus, edit the mapping file to reflect this. To change nisplusObject, for example, to myObject, add nisplusObject=myObject to the filterAttrValList and attrValList portions of the readObjectSpec and writeObjectSpec of the nisplusLDAPobjectDN value for the mapping. See the description of nisplusLDAPobjectDN below.

9. Refer to your LDAP server documentation for how to create attributes and object classes, and set up the following. The following is LDIF data for ldapadd(1). Attribute and object class OIDs are examples only.

```
dn: cn=schema
changetype: modify
add: attributetypes
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.4.0 NAME 'nisplusEntryOwner' \
DESC 'Opaque representation of NIS+ entry owner' \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 SINGLE-VALUE )
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.4.1 NAME 'nisplusEntryGroup' \
DESC 'Opaque representation of NIS+ entry group' \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 SINGLE-VALUE )
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.4.2 NAME 'nisplusEntryAccess' \
DESC 'Opaque representation of NIS+ entry access' \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 SINGLE-VALUE )
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.4.3 NAME 'nisplusEntryTtl' \
DESC 'Opaque representation of NIS+ entry TTL' \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 SINGLE-VALUE )

dn: cn=schema
changetype: modify
add: objectclasses
objectclasses: ( 1.3.6.1.4.1.42.2.27.5.42.42.5.0 NAME 'nisplusEntryData' \
SUP top STRUCTURAL DESC 'NIS+ entry object non-column data' \
MUST ( cn ) MAY ( nisplusEntryOwner $ nisplusEntryGroup $ \
nisplusEntryAccess $ nisplusEntryTtl ) )
```

Edit the mapping file to enable storing entry owner, group, access, and TTL in LDAP. The template mapping file /var/nis/NIS+LDAPmapping.template has commented-out sections for the passwd and cred database ids that show how this can be done.

10. To preserve the cname and auth_name column data when cred.org_dir entries are stored in NIS+, you can create the nisplusPrincipalName and nisplusNetname attributes. See your LDAP server documentation for how to create attributes and object classes, and set up the following:

```

dn: cn=schema
changetype: modify
add: attributetypes
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.7.0 NAME 'nisplusPrincipalName' \
DESC 'NIS+ principal name' \
EQUALITY caseIgnoreIA5Match SINGLE-VALUE \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )
attributetypes: ( 1.3.6.1.4.1.42.2.27.5.42.42.9.0 NAME 'nisplusNetname' \
DESC 'Secure RPC netname' \
EQUALITY caseIgnoreIA5Match SINGLE-VALUE \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )

```

```

dn: cn=schema
changetype: modify
add: objectclasses
objectclasses: ( 1.3.6.1.4.1.42.2.27.5.42.42.10.0 NAME 'nisplusAuthName' \
SUP top AUXILIARY DESC 'NIS+ authentication identifiers' \
MAY ( nisplusPrincipalName $ nisplusNetname ) )

```

Edit the mapping file to use the new `nisplusPrincipalName` and `nisplusNetname`. The template `/var/nis/NIS+LDAPmapping` file contains commented-out sections that support the `nisplusPrincipalName` and `nisplusNetname` attributes. See the `nisplusLDAPobjectDN`, `nisplusLDAPattributeFromColumn` and `nisplusLDAPcolumnFromAttribute` attribute values for the `credlocal`, `creduser`, and `crednode` database ids .

Attributes for Data Mapping

The following attributes are recognized. Any values specified for these attributes in the file, including an empty value, override values obtained from LDAP. However, note that the `nisplusLDAPconfig*` values are read from this file and the command line only. They are not obtained from LDAP.

There are several attributes that can have multiple values, one for each database id. Depending on the source, the multiple values are specified in the following ways:

LDAP	Multi-valued attributes, where each value corresponds to one database id.
File	One line, which may be continued, for each value (database id). The line starts with the name of the attribute
Command	-x option for each value (database id).

Unless otherwise noted, all elements of the syntaxes below may be surrounded by white space. Separator characters and white space must be escaped if they are part of syntactic elements.

`nisplusLDAPdatabaseIdMapping`

Maps a database id to a NIS+ object. If the object name is not fully qualified, that is, it does not end in a dot, the `nisplusLDAPbaseDomain` is appended. There is no default value. The syntax of the value is:

```
databaseId ":" objectspec
```

NIS+LDAPmapping(4)

where	
databaseId	Label identifying a subset of a NIS+ object for mapping purposes.
objectspec	objectname "[" indexlist "]" tablename
objectname	The name of a NIS+ object (including tables)
tablename	The name of a NIS+ table
indexlist	colspec ["," colspec]
colspec	colname "=" colvalue
colname	The name of a column in the table
colvalue	colvaluestring "\" colvaluestring \""

The [indexlist] tablename form is intended for those cases where it is necessary to select a subset of a NIS+ table. The subset are those NIS+ entries that match the indexlist. If there are multiple indexed specifications for a particular NIS+ table, they are tried in the order retrieved until one matches. Note that retrieval order usually is unspecified for multi-valued LDAP attributes. Hence, if using indexed specifications when nisplusLDAPdatabaseIdMapping is retrieved from LDAP, make sure that the subset match is unambiguous.

If the colvaluestring contains white space or commas, it must either be surrounded by double quotes, or the special characters must be escaped. Wildcards are allowed in the colvaluestring. If the objectname or tablename is not fully qualified, the nisplusLDAPbaseDomain value is appended. If the objectname is empty the value of nisplusLDAPbaseDomain is substituted.

Represent the passwd.org_dir table by the passwd database id. The following is an example:

```
passwd:passwd.org_dir
```

Associate the LOCAL entries in the cred.org_dir table with the credlocal database id. The following is an example:

```
credlocal:[auth_type=LOCAL]cred.org_dir
```

Use the creduser database id for those entries in the cred.org_dir table that represent credentials (keys) for users. That is, they have a netname (auth_name) of the type unix.<numeric-id>@domain. The following is an example:

```
creduser:[auth_type="D*",auth_name="unix.[0-9]*"]cred.org_dir
```

nisplusLDAPentryTtl

Establish TTLs for NIS+ entries derived from LDAP. The syntax of the value is:

```
databaseId ":" initialTTLlo ":" initialTTLhi ":" runningTTL
```

<code>initialTTLlo</code>	The lower limit for the initial TTL (in seconds) for data read from disk when the <code>rpc.nisd</code> starts, or from LDAP during an initial down-load. See <code>rpc.nisd(4)</code> for the description of the <code>nisplusLDAPinitialUpdate</code> attribute. If <code>initialTTLhi</code> also is specified, the actual <code>initialTTL</code> will be randomly selected from the interval <code>initialTTLlo</code> to <code>initialTTLhi</code> , inclusive. If the field is left empty, it yields the default value of 1800 seconds.
<code>initialTTLhi</code>	The upper limit for the initial TTL. If left empty, it defaults to 5400.
<code>runningTTL</code>	The TTL (in seconds) for data retrieved from LDAP while the <code>rpc.nisd</code> is running. Leave the field empty to obtain the default value of 3600 seconds.

If there is no specification of TTLs for a particular `databaseId`, the default values are used. If the `initialTTLlo` and `initialTTLhi` have the same value, the effect will be that all data known to the `rpc.nisd` at startup times out at the same time. Depending on NIS+ data lookup patterns, this could cause spikes in `rpc.nisd`-to-LDAP traffic. In order to avoid that, you can specify different `initialTTLlo` and `initialTTLhi` values and obtain a spread in initial TTLs. The NIS+ object TTL is a separate and distinct entity used for other purposes, notably the TTL of NIS+ directory objects in the shared directory cache managed by the `nis_cachemgr(1M)`. There is no connection between the `nisplusLDAPentryTtl` and object TTL values for a NIS+ object.

Entries in the NIS+ hosts table read from LDAP should be valid for four hours. When the `rpc.nisd` restarts, the disk database entries are valid for between two and three hours. The following is an example:

```
hosts:7200:10800:14400
```

```
nisplusLDAPobjectDN
```

Specifies the connection between a `databaseId`, a NIS+ object or part of a NIS+ table, and the LDAP directory. The syntax of the value is:

```
databaseId ":" objectDN *( ";" objectDN )
objectDN          readObjectSpec [":" [writeObjectSpec]]
readObjectSpec    [baseAndScope [filterAttrValList]]
writeObjectSpec    [baseAndScope [attrValList [":"
deleteDisp]]]
baseAndScope      [baseDN] ["?" [scope]]
filterAttrValList ["?" [filter | attrValList]]
scope              "base" | "one" | "sub"
```

NIS+LDAPmapping(4)

<code>attrValList</code>	attribute "=" value *(", " attribute "=" value)
<code>deleteDisp</code>	"always" <code>perDbId</code> "never"
<code>perDbId</code>	"dbid" "=" <code>delDatabaseId</code>
<code>delDatabaseId</code>	database id per <code>nisplusLDAPdatabaseIdMapping</code> above.

The `baseDN` defaults to the value of the `defaultSearchBase` attribute. If the `baseDN` ends in a comma, the `defaultSearchBase` is appended. `scope` defaults to one. It has no meaning and is ignored in a `writeObjectSpec`. The `filter` is an LDAP search filter. There is no default value. The `attrValList` is a list of attribute and value pairs. There is no default value. As a convenience, if an `attrValList` is specified in a `readObjectSpec`, it is converted to a search filter by ANDing together the attributes and values. For example, the attribute and value list:

```
objectClass=posixAccount,objectClass=shadowAccount
```

is converted to the filter:

```
(&(objectClass=posixAccount)\
(objectClass=shadowAccount))
```

Entry objects are mapped by means of the relevant table mapping rules in the `nisplusLDAPattributeFromColumn` and `nisplusLDAPcolumnFromAttribute` attributes. Entry objects do not have explicit `nisplusLDAPobjectDN` attributes.

If a `writeObjectSpec` is omitted, and there is no trailing colon, the effect is to not attempt writes at all. If there is a trailing colon after the `readObjectSpec`, it is implied that the `writeObjectSpec` is the same as the `readObjectSpec`.

Note that writes only are attempted by a master server for the mapped NIS+ object. Replicas silently ignore any `writeObjectSpec:s`.

The `deleteDisp` specifies how NIS+ object deletion should be reflected in LDAP. The following values are recognized:

<code>always</code>	Always attempt to remove the LDAP entry. This is the default.
<code>dbid=delDatabaseId</code>	Set the mapped entries to values specified by the <code>nisplusLDAPattributeFromColumn</code> attribute values for <code>delDatabaseId</code> . This only makes sense for the <code>databaseId:s</code> corresponding to NIS+ tables or subsets of subsets. For other NIS+ objects, if <code>dbid=</code> is specified, the action will be <code>always</code> . In the <code>delDatabaseId</code> , deletion of individual attributes can be specified by leaving the RHS of the = in a mapping rule empty. The <code>delDatabaseId</code> rule set should specify a dn. Otherwise, the <code>rpc.nisd</code> might try to derive a dn by performing

an LDAP lookup on the attributes and values from the rule set, quite possibly with unexpected results.

never Upon NIS+ object deletion, the corresponding LDAP data is left unchanged. If the NIS+ object is an entry, this means that the only effect of the deletion is to temporarily remove it from the `rpc.nisd`'s cache.

The following is an example of how to get the `ipnodes` table entries from the `ou=Hosts` container under the default search base, and write to the same place.

```
ipnodes:ou=Hosts,?one?objectClass=ipHost:
```

The following example shows how to obtain the `passwd` table entries from the `ou=People` containers under the default search base, and also from `dc=another,dc=domain`. The latter is an example of the equivalent of and replacement for a NIS+ table path. Writes should only be attempted to the `first` objectDN. NIS+ entry deletions are not reflected in LDAP:

```
passwd:ou=People,?one?objectClass=shadowAccount,\
      objectClass=posixAccount::never;\
      ou=People,dc=another,dc=domain,?one?\
      objectClass=shadowAccount,\
      objectClass=posixAccount
```

The following example shows how to obtain the `passwd` table entries from the `ou=People` container under the default search base. Upon NIS+ entry deletion, update the LDAP entry per the `passwd_delete` database id:

```
passwd:ou=People,?one?objectClass=shadowAccount,\
      objectClass=posixAccount:\
      dbid=passwd_delete
```

where `nisplusLDAPAttributeFromColumn` for `passwd_delete` could be:

```
passwd_delete:\
  dn=("uid=%s,", name), \
  uid=name, \
  userPassword=("*NP*"), \
  uidNumber=uid, \
  gidNumber=gid, \
  gecos=("INVALID: %s", gecos), \
  homeDirectory=home, \
  loginShell=("/bin/false"), \
  (shadowLastChange,shadowMin,shadowMax, \
   shadowWarning, shadowInactive,shadowExpire, \
   shadowFlag)=(shadow, ":"), \
  nisplusEntryOwner=zo_owner, \
  nisplusEntryGroup=zo_group, \
  nisplusEntryAccess=zo_access
```

`nisplusLDAPcolumnFromAttribute`

Specifies how a NIS+ table and column value is derived from LDAP attribute values. The syntax is:

NIS+LDAPmapping(4)

```
databaseId ":" colattrspec *(", " colattrspec)
```

The format of `colattrspec` is shown below in the discussion of the column and attribute conversion syntax.

The following is an example of how to map by direct copy and assignment the value of the `ipHostNumber` attribute to the `addr` column:

```
addr=ipHostNumber
```

Formats for the column and attribute conversion syntax are discussed below, including examples of complex attribute to column conversions..

There are four special pseudo-columns that are used to indicate non-column entry object data:

<code>zo_owner</code>	The NIS+ principal that owns the entry object. By default, the <code>zo_owner</code> value is inherited from the table owner.
<code>zo_group</code>	The NIS+ group owner of the entry object. By default, the <code>zo_group</code> value is inherited from the table owner .
<code>zo_access</code>	The NIS+ access rights to the entry. Table column rights are stored in the table. By default, the <code>zo_access</code> value is inherited from the table owner .
<code>zo_ttl</code>	The NIS+ TTL for the entry. This is not the TTL for the entry when cached by the <code>rpc.nisd</code> . By default, the <code>zo_ttl</code> value is inherited from the table owner .

The default `/var/nis/NIS+LDAPmapping.template` assumes the existence of the following corresponding LDAP attributes in the containers for the `passwd` and `cred` tables:

```
nisplusEntryOwner  
nisplusEntryGroup  
nisplusEntryAccess  
nisplusEntryTtl
```

These attributes are not part of any schema specified in an *RFC* or similar document. They must be created if they are to be used. They are assumed to belong to the `nisplusEntryData` object class, and they contain a single string value. The format of this string is private, and subject to change without notice.

For most tables, the non-column entry data can be inherited from the containing table, and the pseudo-columns should be left unmapped. Notable exceptions are the `passwd` and `cred` tables, if individual users have access to modify their own `passwd` and `cred` entries. This would usually be the case if the site is not running the `rpc.nispasswd(1M)` daemon.

`nisplusLDAPattributeFromColumn`

Specifies how an LDAP attribute value is derived from NIS+ table and column values. The syntax is:

```
databaseId ":" colattrspec *(", " colattrspec )
```

The format of `colattrspec` is shown below in the discussion of the column and attribute conversion syntax.

As a special case, if the `dn` attribute value derived from a `colattrspec` ends in a comma (','), the `baseDN` from the `writeObjectSpec` is appended.

The following is an example of how to map the value of the `addr` column to the `ipHostNumber` attribute by direct copy and assignment:

```
ipHostNumber=addr
```

All relevant attributes, including the `dn`, must be specified. Non-column entry object data can be mapped as noted under the discussion of `nisplusLDAPcolumnFromAttribute` above.

Column and Attribute Conversion Syntax

The general format of a `colattrspec` is:

```
colattrspec = lhs "=" rhs
lhs         = lval | namespeclist
rhs         = rval | [namespec]
namespeclist = namespec | "(" namespec *(", " namespec) ")"
```

The `lval` and `rval` syntax are defined below at Values. The format of a `namespec` is:

```
namespec      ["ldap:" attrspec [searchTriple] | ["nis+:" colspec [objectspec]
colspec       column | "(" column ")"
attrspec      attribute | "(" attribute ")"
searchTriple  ":" [baseDN] ["?" [scope] ["?" [filter]]]
baseDN        Base DN for search
filter        LDAP search filter
objectspec    objectspec per nisplusLDAPdatabaseIdMapping
```

The repository specification in a `namespec` defaults as follows:

- For assignments to a column, `nis+:` on the LHS, `ldap:` on the RHS. NIS+ column values on the RHS are those that exist before the NIS+ entry is modified.
- For assignments to an attribute, `ldap:` on the LHS, `nis+:` on the RHS. LDAP attribute values on the RHS are those that exist before the LDAP entry is modified.

Enclosing the column or attribute name in parenthesis denotes a list of column or attribute values. For attributes, the meaning is the list of all attributes of that name,

NIS+LDAPmapping(4)

and the interpretation depends on the context. See the discussion at Values. This list specification is ignored when a `searchTriple` or `objectspec` is supplied.

For columns, the `(colname)` syntax is used to map multiple attribute instances to multiple NIS+ entries.

The `searchTriple` can be used to specify an attribute from a location other than the read or write target. The defaults are as follows:

<code>baseDN</code>	If omitted, the default is the current <code>objectDN</code> . If the <code>baseDN</code> ends in a comma, the value of the <code>defaultSearchBase</code> attribute is appended.
<code>scope</code>	<code>one</code>
<code>filter</code>	Empty

Similarly, the `objectspec` can be used to specify a column value from a NIS+ table other than the one implicitly indicated by the `databaseId`. If `searchTriple` or `objectspec` is explicitly specified in a `namespec`, the retrieval or assignment, whether from or to LDAP or NIS+, is performed without checking if read and write are enabled for the LDAP container or NIS+ table. Omitting the `namespec` in an `rhs` is only allowed if the `lhs` is one or more attributes. The effect is to delete the specified attribute(s). In all other situations, an omitted `namespec` means that the rule is ignored. The `filter` can be a value. See Values. For example, to find the `ipHostNumber` using the `cn`, you could specify the following in the `filter` field:

```
ldap:ipHostNumber:?one?("cn=%s", (cname, "%s.*"))
```

In order to remove ambiguity, the unmodified value of a single column or attribute must be specified as the following when used in the filter field.

```
("%s", namespec)
```

If the `filter` is not specified, the `scope` will be `base`, and the `baseDN` is assumed to be the DN of the entry that contains the attribute to be retrieved or modified. To use previously existing column or attribute values in the mapping rules requires a lookup to find those values. Obviously, this will add to the time required to perform the modification. Also, there is a window between the time when a value is retrieved, and then slightly later, stored back. If the values have changed in the mean time, the change may be overwritten. When `colattrspecs` are grouped into rule sets, in the value of a `nisplusLDAPcolumnFromAttribute` or `nisplusLDAPattributeFromColumn` attribute, the evaluation of the `colattrspecs` proceed in the listed order. However, evaluation may be done in parallel for multiple `colattrspecs`. If there is an error when evaluating a certain `colattrspec`, including retrieval or assignment of entry or column values, the extent to which the other `colattrspec` rules are evaluated is unspecified

Wildcards Where wildcard support is available, it is of the following limited form:

<code>*</code>	Matches any number of characters.
<code>[x]</code>	Matches the character <code>x</code> .

[x-y] Matches any character in the range x to y, inclusive..

Combinations such as [a-cA-C0123] are also allowed. This example would match any one of a, b, c, A, B, C, 0, 1, 2, or 3.

Substring Extraction

```
substringextract = "(" namespec "," matchspec ")"
name             = column or attribute name
matchspec       = "\" formatstring \""
```

The matchspec is a string like the sscanf(3C) format string, except that there may be at most one format specifier, a single %s. The output value of the substringextract is the substring matching the location of the %s.

If there is no %s in the formatstring, it must instead be a single character, which is assumed to be a field separator for the namespec. The output values are the field values. Wild cards are supported. If there is no match, the output value is the empty string, "".

For example, if the column cname has the value user.some.domain.name., the value of the expression:

```
(cname, "%s.*")
```

is user, which can be used to extract the user name from a NIS+ principal name.

Similarly, use this expression to extract the third of the colon-separated fields of the shadow column:

```
(shadow, "*:*:%s:*")
```

This form can be used to extract all of the shadow fields. However, a simpler way to specify that special case is:

```
(shadow, ":")
```

Values

```
lval          "(" formatstring "," namespec *("," namespec) ")"
rval          "(" formatstring [" namespec [" elide ] ] ")"
namelist      name_or_sse * ( "," name_or_sse )
name_or_sse   namespec | substringextract
formatstring  "\" formatstring \""
formatstring  A string combining text and % field specifications
elide         "\" singlechar \""
singlechar    Any character
```

This syntax is used to produce rval values that incorporate column or attribute values, in a manner like sprintf(3C), or to perform assignments to lval like sscanf(3C). One important restriction is that the format specifications, % plus a single character, use the designations from ber_printf(3LDAP). Thus, while %s is used to

NIS+LDAPmapping(4)

extract a string value, %i causes BER conversion from an integer. Formats other than %s, for instance, %i, are only meaningfully defined in simple format strings without any other text.

The following `ber_printf()` format characters are recognized:

```
b i B n o s
```

If there are too few format specifiers, the format string may be repeated as needed.

When used as an `lval`, there is a combination of pattern matching and assignment, possibly to multiple columns or attributes.

For example, in an assignment to an attribute, if the value of the `addr` column is `1.2.3.4`, the `rval`:

```
("ipNetworkNumber=%s", addr)
```

produces the value `ipNetworkNumber=1.2.3.4`, while:

```
("(%s,%s,%s)", host, user, domain)
```

results in (assuming `host="xyzzy"`, `user="-"`, `domain="x.y.z"`) `"(xyzzy, -, x.y.z)"`. The elide character feature is used with attribute lists. For example:

```
("%s", (mgrprfc822mailmember), ",")
```

concatenates all `mgrprfc822mailmember` values into one comma-separated string, and then elides the final trailing comma. Thus, for

```
mgrprfc822mailmember=usera
mgrprfc822mailmember=userb
mgrprfc822mailmember=userc
```

the value would be `usera,userb,userc`.

If the NIS+ column `intval` is in binary format, that is, the `B` column flag is set, and it is to be interpreted as an integer, the following:

```
("%i", intval)
```

produces a value suitable for assignment to an integer-valued attribute.

The `nisPublicKey` attribute encodes the algorithm type and number (equivalent to the `auth_type` column) and the public key as a single string such as `{dh192-0}xxxxxxxx` (public key truncated for clarity). The following will extract the corresponding `auth_type` and `public_data` values:

```
("{%s}%s", auth_type, public_data)
```

As a special case, to combine an LHS extraction with an RHS implicit list creates multiple entries and values. For example,

Assignments

```
("(%s,%s,%s)", host, user, domain)=(nisNetgroupTriple)
```

creates one NIS+ entry for each `nisNetgroupTriple` value.

The assignment syntax, also found at Column and Attribute Conversion Syntax , is as follows:

```
colattrspec    = lhs "=" rhs
lhs             = lval | namespeclist
rhs            = rval | namespec
namespeclist   = namespec | "(" namespec *("," namespec) ")"
```

By using the syntax defined above, the general form of a simple assignment, which is a one-to-one mapping of column to attribute, would be:

```
("%s", colname)=(%s", attrname)
```

As a convenient short-hand, this can also be written as:

```
colname=attrname
```

A list specification, which is a name enclosed in parenthesis, can be used to make many-to-many assignments. The expression:

```
(colname)=(attrname)
```

where there are multiple instances of `attrname`, creates one NIS+ entry for each such instance, differentiated by their `colname` values. The following combinations of lists are allowed, but they are not particularly useful:

```
(attrname)=(colname)    Equivalent to attrname=colname
attrname=(colname)      Equivalent to attrname=colname
(colname)=attrname      Equivalent to colname=attrname
colname=(attrname)     Equivalent to colname=attrname
```

If a multi-valued RHS is assigned to a single-valued LHS, the LHS value will be the first of the RHS values. If the RHS is an attribute list, the first attribute is the first one returned by the LDAP server when queried. Otherwise, the definition of "first" is implementation dependent.

Finally, the LHS might be an explicit list of columns or attributes, such as:

```
(name1, name2, name3)
```

If the RHS is single-valued, this assigns the RHS value to all entities in the list. If the RHS is multi-valued, the first value is assigned to the first entity of the list, the second value to the second entity, and so on. Excess values or entities are silently ignored.

NIS+LDAPmapping(4)

EXAMPLES

EXAMPLE 1 Assigning an Attribute Value to a Column

The following example illustrates how to assign the value of the `ipHostNumber` attribute to the `addr` column

```
addr=ipHostNumber
```

EXAMPLE 2 Creating Multiple NIS+ Entries from Multi-Valued LDAP Attributes

An LDAP entry with:

```
cn=name1
cn=name2
cn=name3
```

and the following assignments:

```
cname=cn
(name) = (cn
```

creates three NIS+ entries (other attributes/columns omitted for clarity):

```
cname=name1, name=name1
cname=name1, name=name2
cname=name1, name=name3
```

EXAMPLE 3 Assigning String Constants

The following expression sets the `auth_type` column to `LOCAL`:

```
auth_type= ("LOCAL")
```

EXAMPLE 4 Splitting Column Values to Multi-Valued Attributes

The `expansion` column contains a comma-separated list of alias member names. In the following example, the expression assigns each such member name to an instance of `mgrprfc822mailmember`:

```
(mgrprfc822mailmember) = (expansion, ",")
```

EXAMPLE 5 Splitting Column Values to Multiple Attributes

The `shadow` column contains a colon-separated list of fields. The following assigns the value of the first field to `shadowLastChange`, the value of the second field to `shadowMin`, and so forth..

```
(shadowLastChange, shadowMin, shadowMax, shadowWarning, \
 shadowInactive, shadowExpire, shadowFlag) = (shadow, ":")
```

FILES

```
/var/nis/NIS+LDAPmapping
Default mapping file used by rpc.nisd(1M).
```

`/var/nis/NIS+LDAPmapping.template`

Template file covering the standard NIS+ directories and tables.

NOTES *RFC 2307bis* is an IETF informational document in draft stage that defines an approach for using LDAP as a naming service.

nodename(4)

NAME	nodename – local source for system name				
SYNOPSIS	<code>/etc/nodename</code>				
DESCRIPTION	<p>When a machine is standalone or its IP address is configured locally, the <code>/etc/nodename</code> file contains the system name. By convention, the system name is the same as the hostname associated with the IP address of the primary network interface, for example, <code>hostname.hme0</code>.</p> <p>If the machine's network configuration is managed remotely and delivered by the DHCP or RPC bootparams protocols, the <code>/etc/nodename</code> file is not used, as the system name is delivered by the remote service.</p> <p>Given a system name value, regardless of source, the <code>uname</code> utility invoked with the <code>-S</code> option is used to set the system name of the running system.</p>				
EXAMPLES	<p>EXAMPLE 1 Syntax</p> <p>The syntax for <code>nodename</code> consists of a single line containing the system's name. For example, for a system named <code>myhost</code>:</p> <pre>myhost</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>nis+(1)</code> , <code>uname(1)</code> , <code>named(1M)</code> , <code>ypbind(1M)</code> , <code>attributes(5)</code>				
NOTES	The <code>nodename</code> file is modified by Solaris installation and de-installation scripts. The user should not edit the file.				

NAME	nologin – message displayed to users attempting to log on in the process of a system shutdown
SYNOPSIS	/etc/nologin
DESCRIPTION	<p>The /etc/nologin file contains the message displayed to users attempting to log on to a machine in the process of being shutdown. After displaying the contents of the nologin file, the login procedure terminates, preventing the user from logging onto the machine.</p> <p>This procedure is preferable to terminating a user's session by shutdown shortly after the user has logged on.</p> <p>Logins by super-user are not affected by this procedure.</p> <p>The message contained in the nologin file is editable by super-user. A typical nologin file contains a message similar to:</p> <p>NO LOGINS: System going down in 10 minutes.</p>
SEE ALSO	login(1), rlogin(1), telnet(1), shutdown(1M)

note(4)

NAME	note – specify legal annotations
SYNOPSIS	<code>/usr/lib/note</code>
DESCRIPTION	<p>Each file in this directory contains the NOTE (also <code>_NOTE</code>) annotations legal for a single tool. The name of the file, by convention, should be the tool vendor's stock name, followed by a hyphen, followed by the tool name. For example, for Sun's <code>lock_lint</code> tool the filename should be <code>SUNW-lock_lint</code>.</p> <p>The file should contain the names of the annotations understood by the tool, one per line. For example, if a tool understands the following annotations:</p> <pre>NOTE (NOT_REACHED) NOTE (MUTEX_PROTECTS_DATA(list_lock, list_head))</pre> <p>then its file in <code>/usr/lib/note</code> should contain the entries:</p> <pre>NOT_REACHED MUTEX_PROTECTS_DATA</pre> <p>Blank lines, and lines beginning with a pound (<code>#</code>), are ignored.</p> <p>While <code>/usr/lib/note</code> is the default directory tools search for such files, they can be made to search other directories instead simply by setting environment variable <code>NOTE_PATH</code> to contain the paths, separated by colons, of directories to be searched, e.g., <code>/usr/mytool/note:/usr/lib/note</code>.</p>
USAGE	<p>These files are used by such tools whenever they encounter NOTES they do not understand. If a file in <code>/usr/lib/note</code> contains the annotation, then it is valid. If no such file contains the annotation, then the tool should issue a warning complaining that it might be invalid.</p>
ENVIRONMENT VARIABLES	<p><code>NOTE_PATH</code> specify paths to be searched for annotation files. Paths are separated by colons ("<code>:</code>").</p>
SEE ALSO	<p>NOTE(3EXT)</p>

NAME	nscd.conf – name service cache daemon configuration
SYNOPSIS	<code>/etc/nscd.conf</code>
DESCRIPTION	<p>The <code>nscd.conf</code> file contains the configuration information for <code>nscd(1M)</code>. Each line specifies either an <i>attribute</i> and a <i>value</i>, or an <i>attribute</i>, <i>cachename</i>, and a <i>value</i>. Fields are separated either by SPACE or TAB characters. A '#' (number sign) indicates the beginning of a comment; characters up to the end of the line are not interpreted by <code>nscd</code>.</p> <p><i>cachename</i> is represented by <code>hosts</code>, <code>ipnodes</code>, <code>passwd</code>, or <code>groups</code>.</p> <p><i>attribute</i> supports the following:</p> <p><code>logfile</code> <i>debug-file-name</i> Specifies name of the file to which debug info should be written. Use <code>/dev/tty</code> for standard output.</p> <p><code>debug-level</code> <i>value</i> Sets the debug level desired. <i>value</i> may range from 0 (the default) to 10. Use of this option causes <code>nscd(1M)</code> to run in the foreground and not become a daemon. Note that the output of the debugging command is not likely to remain the same from release-to-release; scripts should <i>not</i> rely on its format.</p> <p><code>enable-cache</code> <i>cachename value</i> Enables or disables the specified cache. <i>value</i> may be either <code>yes</code> or <code>no</code>.</p> <p><code>positive-time-to-live</code> <i>cachename value</i> Sets the time-to-live for positive entries (successful queries) in the specified cache. <i>value</i> is in integer seconds. Larger values increase cache hit rates and reduce mean response times, but increase problems with cache coherence. Note that sites that push (update) NIS maps nightly can set the value to be the equivalent of 12 hours or more with very good performance implications.</p> <p><code>negative-time-to-live</code> <i>cachename value</i> Sets the time-to-live for negative entries (unsuccessful queries) in the specified cache. <i>value</i> is in integer seconds. Can result in significant performance improvements if there are several files owned by uids (user IDs) not in system databases; should be kept small to reduce cache coherency problems.</p> <p><code>suggested-size</code> <i>cachename value</i> Sets the suggested number of hash buckets in the specified cache. This parameter should be changed only if the number of entries in the cache exceeds the suggested size by more than a factor of four or five. Since this is the internal hash table size, <i>value</i> should remain a prime number for optimum efficiency.</p> <p><code>keep-hot-count</code> <i>cachename value</i> This attribute allows the administrator to set the number of entries <code>nscd(1M)</code> is to keep current in the specified cache. <i>value</i> is an integer number which should approximate the number of entries frequently used during the day.</p>

nscd.conf(4)

check-files cachename value

Enables or disables checking the file belonging to the specified *cachename* for changes. If enabled (which is the default), changes in the corresponding file cause the cache to be invalidated within 10 seconds. Can be disabled if files are never modified for a slight performance boost, particularly over NFS. *value* may be either yes or no.

SEE ALSO nscd(1M), group(4), hosts(4), ipnodes(4), passwd(4)

WARNINGS The `nscd.conf` interface is included in this release on an uncommitted basis only and is subject to change or removal in a future minor release.

NAME	nss – configuration file for initgroups lookup method						
SYNOPSIS	/etc/default/nss						
DESCRIPTION	<p>The /etc/default/nss configuration file controls the behavior of the name service switch routines outside of the source database mappings provided by the /etc/nsswitch.conf file.</p> <p>/etc/default/nss supports the following options:</p> <p>NETID_AUTHORITATIVE Changes the behavior of the name service lookups to use the netid table in response to the initgroups(3C) call. The netid table is provided by the LOCAL entries of the NIS+ cred.org_dir table. By default, initgroups() uses the group table. When NETID_AUTHORITATIVE is set to TRUE, initgroups() will use netid as the source for supplementary groups rather than the group table.</p> <p>The name service administrator must ensure that the netid table contains valid supplementary group information for users. Not all name services can automatically keep the members listed in the group table in sync with the netid table.</p>						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

nsswitch.conf(4)

NAME	nsswitch.conf – configuration file for the name service switch																																						
SYNOPSIS	/etc/nsswitch.conf																																						
DESCRIPTION	<p>The operating system uses a number of databases of information about hosts, ipnodes, users (<code>passwd</code> and <code>shadow</code>), and groups. Data for these can come from a variety of sources: hostnames and host addresses, for example, can be found in <code>/etc/hosts</code>, NIS, NIS+, LDAP, or DNS. Zero or more sources may be used for each database; the sources and their lookup order are specified in the <code>/etc/nsswitch.conf</code> file.</p> <p>The following databases use the switch file:</p> <table><thead><tr><th>Database</th><th>Used By</th></tr></thead><tbody><tr><td>aliases</td><td>sendmail(1M)</td></tr><tr><td>auth_attr</td><td>getauthnam(3SECDB)</td></tr><tr><td>automount</td><td>automount(1M)</td></tr><tr><td>bootparams</td><td>rpc.bootparamd(1M)</td></tr><tr><td>ethers</td><td>ethers(3SOCKET)</td></tr><tr><td>group</td><td>getgrnam(3C)</td></tr><tr><td>hosts</td><td>gethostbyname(3NSL). Database	Used By
sendmailvars	sendmail(1M)
services	getservbyname(3SOCKET).
	See Interaction with netconfig.

The following sources may be used:

Source	Uses
files	/etc/hosts, /etc/passwd, /etc/inet/ipnodes, /etc/shadow
nis	NIS(YP)
nisplus	NIS+
ldap	LDAP
dns	Valid only for hosts; uses the Internet Domain Name Service.
compat	Valid only for passwd and group; implements "+" and "-". See Interaction with +/- syntax.
user	Valid only for printers; implements support for \${HOME}/.printers.
xfn	Valid only for printers; implements support for FNS printer contexts. Provided to allow transition away from FNS printer contexts.

There is an entry in `/etc/nsswitch.conf` for each database. Typically these entries will be simple, such as "protocols: files" or "networks: files nisplus". However, when multiple sources are specified, it is sometimes necessary to define precisely the circumstances under which each source will be tried. A source can return one of the following codes:

Status	Meaning
SUCCESS	Requested database entry was found.
UNAVAIL	Source is not configured on this system or internal failure.
NOTFOUND	Source responded "no such entry"
TRYAGAIN	Source is busy or not responding, might respond to retries.

For each status code, two actions are possible:

Action	Meaning
continue	Try the next source in the list.
return	Return now.

Additionally, for TRYAGAIN only, the following actions are possible:

Action	Meaning
forever	Retry the current source forever.
<i>n</i>	Retry the current source <i>n</i> more times, where <i>n</i> is an integer between 0 and MAX_INT (that is, 2.14 billion). After <i>n</i> retries has been exhausted, the action will continue to the next source.

The complete syntax of an entry is:

```
<entry> ::= <database> ":" [<source>
[<criteria>]]*
<criteria> ::= "[" <criteria>+ "]"
<criteria> ::= <status> "=" <action>
<status> ::= "success" | "notfound" | "unavail" | "tryagain"
```

For every status except TRYAGAIN, the action syntax is:

```
<action> ::= "return" | "continue"
```

For the TRYAGAIN status, the action syntax is:

```
<action> ::= "return" | "continue" | "forever" | <n>
<n> ::= 0...MAX_INT
```

Each entry occupies a single line in the file. Lines that are blank, or that start with white space, are ignored. Everything on a line following a # character is also ignored; the # character can begin anywhere in a line, to be used to begin comments. The <database> and <source> names are case-sensitive, but <action> and <status> names are case-insensitive.

The library functions contain compiled-in default entries that are used if the appropriate entry in nsswitch.conf is absent or syntactically incorrect.

The default criteria for DNS and the NIS server in "DNS-forwarding mode" (and DNS server not responding or busy) is [SUCCESS=return NOTFOUND=continue UNAVAIL=continue TRYAGAIN=continue].

The default criteria for all other sources is [SUCCESS=return NOTFOUND=continue UNAVAIL=continue TRYAGAIN=forever].

The default, or explicitly specified, criteria are meaningless following the last source in an entry; and they are ignored, since the action is always to return to the caller irrespective of the status code the source returns.

**Interaction with
netconfig**

In order to ensure that they all return consistent results, `gethostbyname(3NSL)`, `getipnodebyname(3SOCKET)`, `getservbyname(3SOCKET)`, and `netdir_getbyname(3NSL)` functions are all implemented in terms of the same internal library function. This function obtains the system-wide source lookup policy for `hosts`, `ipnodes`, and `services` based on the `inet` family entries in `netconfig(4)` and uses the switch entries only if the `netconfig` entries have a "-" in the last column for `nametoaddr` libraries. See the NOTES section in `gethostbyname(3NSL)` and `getservbyname(3SOCKET)` for details.

**YP-compatibility
Mode**

The NIS+ server can be run in "YP-compatibility mode", where it handles NIS (YP) requests as well as NIS+ requests. In this case, the clients get much the same results (except for `getspnam(3C)`) from the "nis" source as from "nisplus"; however, "nisplus" is recommended instead of "nis".

**Interaction with
server in
DNS-forwarding
Mode**

The NIS (YP) server can be run in "DNS-forwarding mode", where it forwards lookup requests to DNS for host-names and -addresses that do not exist in its database. In this case, specifying "nis" as a source for "hosts" is sufficient to get DNS lookups; "dns" need not be specified explicitly as a source.

In SunOS 5.3 (Solaris 2.3) and compatible versions, the NIS+ server in "NIS/YP-compatibility mode" can also be run in "DNS-forwarding mode" (see `rpc.nisd(1M)`). Forwarding is effective only for requests originating from its YP clients; "hosts" policy on these clients should be configured appropriately.

**Interaction with
Password Aging**

When password aging is turned on, only a limited set of possible name services are permitted for the `passwd:` database in the `/etc/nsswitch.conf` file:

```
passwd:          files
passwd:          files nis
passwd:          files nisplus
passwd:          files ldap
passwd:          compat
passwd_compat:  nisplus
passwd_compat:  ldap
```

nsswitch.conf(4)

Any other settings will cause the `passwd(1)` command to fail when it attempts to change the password after expiration and will prevent the user from logging in. These are the *only* permitted settings when password aging has been turned on. Otherwise, you can work around incorrect `passwd:` lines by using the `-r repository` argument to the `passwd(1)` command and using `passwd -r repository` to override the `nsswitch.conf` settings and specify in which name service you want to modify your password.

**Interaction with
+/- syntax**

Releases prior to SunOS 5.0 did not have the name service switch but did allow the user some policy control. In `/etc/passwd` one could have entries of the form `+user` (include the specified user from NIS `passwd.byname`), `-user` (exclude the specified user) and `+` (include everything, except excluded users, from NIS `passwd.byname`). The desired behavior was often "everything in the file followed by everything in NIS", expressed by a solitary `+` at the end of `/etc/passwd`. The switch provides an alternative for this case ("`passwd: files nis`") that does not require `+` entries in `/etc/passwd` and `/etc/shadow` (the latter is a new addition to SunOS 5.0, see `shadow(4)`).

If this is not sufficient, the NIS/YP compatibility source provides full `+/-` semantics. It reads `/etc/passwd` for `getpwnam(3C)` functions and `/etc/shadow` for `getspnam(3C)` functions and, if it finds `+/-` entries, invokes an appropriate source. By default, the source is "nis", but this may be overridden by specifying "nisplus" or "ldap" as the source for the pseudo-database `passwd_compat`.

Note that for every `/etc/passwd` entry, there should be a corresponding entry in the `/etc/shadow` file.

The NIS/YP compatibility source also provides full `+/-` semantics for `group`; the relevant pseudo-database is `group_compat`.

**Useful
Configurations**

The compiled-in default entries for all databases use NIS (YP) as the enterprise level name service and are identical to those in the default configuration of this file:

<code>passwd:</code>	<code>files nis</code>
<code>group:</code>	<code>files nis</code>
<code>hosts:</code>	<code>nis [NOTFOUND=return] files</code>
<code>ipnodes:</code>	<code>nis [NOTFOUND=return] files</code>
<code>networks:</code>	<code>nis [NOTFOUND=return] files</code>
<code>protocols:</code>	<code>nis [NOTFOUND=return] files</code>
<code>rpc:</code>	<code>nis [NOTFOUND=return] files</code>
<code>ethers:</code>	<code>nis [NOTFOUND=return] files</code>
<code>netmasks:</code>	<code>nis [NOTFOUND=return] files</code>
<code>bootparams:</code>	<code>nis [NOTFOUND=return] files</code>

```

publickey:          nis [NOTFOUND=return] files
netgroup:           nis
automount:          files nis
aliases:            files nis
services:           files nis
sendmailvars:       files
printers:           user files nis nisplus xfn
auth_attr           files nis
prof_attr           files nis
project             files nis

```

The policy "nis [NOTFOUND=return] files" implies "if nis is UNAVAIL, continue on to files, and if nis returns NOTFOUND, return to the caller; in other words, treat nis as the authoritative source of information and try files only if nis is down." This, and other policies listed in the default configuration above, are identical to the hard-wired policies in SunOS releases prior to 5.0.

If compatibility with the +/- syntax for passwd and group is required, simply modify the entries for passwd and group to:

```

passwd:             compat
group:              compat

```

If NIS+ is the enterprise level name service, the default configuration should be modified to use nisplus instead of nis for every database on client machines. The file /etc/nsswitch.nisplus contains a sample configuration that can be copied to /etc/nsswitch.conf to set this policy.

If LDAP is the enterprise level name service, the default configuration should be modified to use ldap instead of nis for every database on client machines. The file /etc/nsswitch.ldap contains a sample configuration that can be copied to /etc/nsswitch.conf to set this policy.

If the use of +/- syntax is desired in conjunction with nisplus, use the following four entries:

```

passwd:             compat
passwd_compat:     nisplus OR ldap
group:              compat
group_compat:      nisplus OR ldap

```

nsswitch.conf(4)

In order to get information from the Internet Domain Name Service for hosts that are not listed in the enterprise level name service, NIS+ or LDAP, use the following configuration and set up the `/etc/resolv.conf` file (see `resolv.conf(4)` for more details):

```
hosts:                               nisplus dns [NOTFOUND=return] files
```

or

```
hosts:                               ldap dns [NOTFOUND=return] files
```

**Enumeration -
getXXXent()**

Many of the databases have enumeration functions: `passwd` has `getpwent()`, `hosts` has `gethostent()`, and so on. These were reasonable when the only source was `files` but often make little sense for hierarchically structured sources that contain large numbers of entries, much less for multiple sources. The interfaces are still provided and the implementations strive to provide reasonable results, but the data returned may be incomplete (enumeration for `hosts` is simply not supported by the `dns` source), inconsistent (if multiple sources are used), formatted in an unexpected fashion (for a host with a canonical name and three aliases, the `nisplus` source will return four hostents, and they may not be consecutive), or very expensive (enumerating a `passwd` database of 5,000 users is probably a bad idea). Furthermore, multiple threads in the same process using the same reentrant enumeration function (`getXXXent_r()` are supported beginning with SunOS 5.3) share the same enumeration position; if they interleave calls, they will enumerate disjoint subsets of the same database.

In general, the use of the enumeration functions is deprecated. In the case of `passwd`, `shadow`, and `group`, it may sometimes be appropriate to use `fgetgrent()`, `fgetpwent()`, and `fgetspent()` (see `getgrnam(3C)`, `getpwnam(3C)`, and `getspnam(3C)`, respectively), which use only the `files` source.

FILES

A source named `SSS` is implemented by a shared object named `nss_SSS.so.1` that resides in `/usr/lib`.

<code>/etc/nsswitch.conf</code>	Configuration file.
<code>/usr/lib/nss_compat.so.1</code>	Implements "compat" source.
<code>/usr/lib/nss_dns.so.1</code>	Implements "dns" source.
<code>/usr/lib/nss_files.so.1</code>	Implements "files" source.
<code>/usr/lib/nss_nis.so.1</code>	Implements "nis" source.
<code>/usr/lib/nss_nisplus.so.1</code>	Implements "nisplus" source.
<code>/usr/lib/nss_ldap.so.1</code>	Implements "ldap" source.
<code>/usr/lib/nss_user.so.1</code>	Implements "user" source.
<code>/usr/lib/nss_xfn.so.1</code>	Implements "xfn" source.

nsswitch.conf(4)

/etc/netconfig	Configuration file for netdir(3NSL) functions that redirects hosts/devices policy to the switch.
/etc/nsswitch.files	Sample configuration file that uses "files" only.
/etc/nsswitch.nis	Sample configuration file that uses "files" and "nis".
/etc/nsswitch.nisplus	Sample configuration file that uses "files" and "nisplus".
/etc/nsswitch.ldap	Sample configuration file that uses "files" and "ldap".
/etc/nsswitch.dns	Sample configuration file that uses "files" and "dns" (but only for hosts:).

SEE ALSO ldap(1), newtask(1), nis+(1), passwd(1), automount(1M), ifconfig(1M), rpc.bootparamd(1M), rpc.nisd(1M), sendmail(1M), getausernam(3BSM), getgrnam(3C), getnetgrent(3C), getpwnam(3C), getsppnam(3C), gethostbyname(3NSL), getpublickey(3NSL), getrpcbyname(3NSL), netdir(3NSL), secure_rpc(3NSL), getprojent(3PROJECT), getdefaultproj(3PROJECT), inproj(3PROJECT), setproject(3PROJECT), getauthnam(3SECDB), getexecprof(3SECDB), getprofnam(3SECDB), getusernam(3SECDB), ethers(3SOCKET), getipnodebyname(3SOCKET), getnetbyname(3SOCKET), getprotobyname(3SOCKET), getservbyname(3SOCKET), netconfig(4), project(4), resolv.conf(4), ypfiles(4)

NOTES Within each process that uses `nsswitch.conf`, the entire file is read only once; if the file is later changed, the process will continue using the old configuration.

Programs that use the `getXXbyYY()` functions cannot be linked statically since the implementation of these functions requires dynamic linker functionality to access the shared objects `/usr/lib/nss_XXX.so.1` at run time.

The use of both `nis` and `nisplus` as sources for the same database is strongly discouraged since both the name services are expected to store similar information and the lookups on the database may yield different results depending on which name service is operational at the time of the request. The same applies for using `ldap` along with `nis` or `nisplus`.

Misspelled names of sources and databases will be treated as legitimate names of (most likely nonexistent) sources and databases.

The following functions do *not* use the switch: `fgetgrent(3C)`, `fgetprojent(3PROJECT)`, `fgetpwent(3C)`, `fgetspent(3C)`, `getpw(3C)`, `putpwent(3C)`, `shadow(4)`.

order(4)

NAME	order – package installation order description file
DESCRIPTION	<p>The package installation order file, <code>.order</code>, is an ASCII file specifying the order in which packages must be installed based on their prerequisite dependencies. Any package with prerequisite dependencies must be installed <i>after</i> any packages it lists as a prerequisite dependency in its <code>depend</code> file.</p> <p>A <code>.order</code> file is required for the OS product. The <code>.order</code> file must reside in the top-level directory containing the product.</p> <p>The ordering is specified as a list of package identifiers, from the first package to be installed to the last, one package identifier per line.</p>
NOTES	The <code>depend</code> file supports <i>incompatible</i> and <i>reverse</i> dependencies. These dependency types are not recognized in the <code>order</code> file.
SEE ALSO	<code>cdtoc(4)</code> , <code>clustertoc(4)</code> , <code>depend(4)</code> , <code>packagetoc(4)</code> , <code>pkginfo(4)</code>

NAME	ott – FACE object architecture information
DESCRIPTION	<p>The FACE object architecture stores information about object-types in an ASCII file named <code>.ott</code> (object type table) that is contained in each directory. This file describes all of the objects in that directory. Each line of the <code>.ott</code> file contains information about one object in pipe-separated fields. The fields are (in order):</p> <p><i>name</i> the name of the actual system file.</p> <p><i>dname</i> the name that should be displayed to the user, or a dot if it is the same as the name of the file.</p> <p><i>description</i> the description of the object, or a dot if the description is the default (the same as object-type).</p> <p><i>object-type</i> the FACE internal object type name.</p> <p><i>flags</i> object specific flags.</p> <p><i>mod time</i> the time that FACE last modified the object. The time is given as number of seconds since 1/1/1970, and is in hexadecimal notation.</p> <p><i>object information</i> an optional field, contains a set of semi-colon separated <i>name=value</i> fields that can be used by FACE to store any other information necessary to describe this object.</p>
FILES	<code>.ott</code> is created in any directory opened by FACE.

packagetoc(4)

NAME	packagetoc – package table of contents description file												
DESCRIPTION	<p>The package table of contents file, <code>.packagetoc</code>, is an ASCII file containing all of the information necessary for installing a product release distributed in package form. It centralizes and summarizes all of the relevant information about each package in the product. This allows the install software to quickly read one file to obtain all of the relevant information about each package instead of having to examine each package at run time to obtain this information. The <code>.packagetoc</code> file resides in the top-level directory containing the product.</p> <p>If a <code>.packagetoc</code> file exists for a product, there must also be a <code>.order</code> file.</p> <p>Each entry in the <code>.packagetoc</code> file is a line that establishes the value of a parameter in the following form:</p> <pre>PARAM=<i>value</i></pre> <p>A line starting with a pound-sign, “#”, is considered a comment and is ignored.</p> <p>Parameters are grouped by package. The start of a package description is defined by a line of the form:</p> <pre>PKG=<i>value</i></pre> <p>There is no order implied or assumed for specifying the parameters for a package with the exception of the <code>PKG</code> parameter, which must appear first. Only one occurrence of a parameter is permitted per package.</p> <p>The parameters recognized are described below. Those marked with an asterisk are mandatory.</p> <table><tr><td><code>PKG*</code></td><td>The package identifier (for example, <code>SUNWaccu</code>) . The maximum length of the identifier is nine characters. All the characters must be alphanumeric. The first character must be alphabetic. <code>install</code>, <code>new</code>, and <code>all</code> are reserved identifiers.</td></tr><tr><td><code>PKGDIR*</code></td><td>The name of the directory containing the package. This directory is relative to the directory containing the product.</td></tr><tr><td><code>NAME*</code></td><td>The full name of the package.</td></tr><tr><td><code>VENDOR</code></td><td>The name of the package’s vendor.</td></tr><tr><td><code>VERSION</code></td><td>The version of the package.</td></tr><tr><td><code>PRODNAME</code></td><td>The name of the product to which this package belongs.</td></tr></table>	<code>PKG*</code>	The package identifier (for example, <code>SUNWaccu</code>) . The maximum length of the identifier is nine characters. All the characters must be alphanumeric. The first character must be alphabetic. <code>install</code> , <code>new</code> , and <code>all</code> are reserved identifiers.	<code>PKGDIR*</code>	The name of the directory containing the package. This directory is relative to the directory containing the product.	<code>NAME*</code>	The full name of the package.	<code>VENDOR</code>	The name of the package’s vendor.	<code>VERSION</code>	The version of the package.	<code>PRODNAME</code>	The name of the product to which this package belongs.
<code>PKG*</code>	The package identifier (for example, <code>SUNWaccu</code>) . The maximum length of the identifier is nine characters. All the characters must be alphanumeric. The first character must be alphabetic. <code>install</code> , <code>new</code> , and <code>all</code> are reserved identifiers.												
<code>PKGDIR*</code>	The name of the directory containing the package. This directory is relative to the directory containing the product.												
<code>NAME*</code>	The full name of the package.												
<code>VENDOR</code>	The name of the package’s vendor.												
<code>VERSION</code>	The version of the package.												
<code>PRODNAME</code>	The name of the product to which this package belongs.												

PRODVERS	The version of the product to which this package belongs.
SUNW_PKGTYPE	<p>The package type. Valid values are:</p> <p><code>root</code> indicates that the package will be installed in the <code>/</code> file system. The <code>root</code> packages are the only packages installed during dataless client installations. The <code>root</code> packages are spooled during a server installation to allow the later installation of diskless clients.</p> <p><code>usr</code> indicates that the package will be installed in the <code>/usr</code> file system.</p> <p><code>kvm</code> indicates that the package will be installed in the <code>/usr/platform</code> file system.</p> <p><code>ow</code> indicates a package that is part of the bundled OpenWindows product release. If no <code>SUNW_PKGTYPE</code> macro is present, the package is assumed to be of type <code>usr</code>.</p>
ARCH*	<p>The architecture(s) supported by the package. This macro is taken from the package's <code>pkginfo(4)</code> file and is subject to the same length and formatting constraints.</p> <p>The install program currently assumes that exactly one architecture token is specified for a package. For example, <code>ARCH=sparc.sun4c</code> is acceptable, but <code>ARCH=sparc.sun4c, sparc.sun4m</code> is not.</p>
DESC	A detailed textual description of the package.
BASEDIR*	The default installation base directory of the package.
SUNW_PDEPEND	A dependency specification for a prerequisite package. Each prerequisite dependency must appear as a separate macro. See <code>depend(4)</code> for more information on dependencies and instance specifications.
SUNW_IDEPEND	A dependency specification for an incompatible package. Each incompatible dependency should appear as a separate macro. See <code>depend(4)</code> for more information on dependencies and instance specifications.
SUNW_RDEPEND	A dependency specification for a reversed package dependency. Each reverse dependency should appear

packagetoc(4)

	as a separate macro. See <code>depend(4)</code> for more information on dependencies and instance specifications.
CATEGORY	The category of the package.
SUNW_LOC	Indicates that this package contains localizations for other packages. Such localization packages are treated as special case packages. Each package which has a <code>SUNW_LOC</code> macro must have a corresponding <code>SUNW_PKGLIST</code> macro. The value specified by this macro should be a valid locale.
SUNW_PKGLIST	A comma separated list of package identifiers. Currently this macro is used to indicate which packages are localized by a localization package.
ROOTSIZE*	The space used by the package in the <code>/</code> file system.
USRSIZE*	The space used by the package in the <code>/usr</code> subtree of the file system.
VARSIZE*	The space used by the package in the <code>/var</code> subtree of the file system.
OPTSIZE*	The space used by the package in the <code>/opt</code> subtree of the file system.
EXPORTSIZE*	The space used by the package in the <code>/export</code> subtree of the file system.
USROWNSIZE*	The space used by the package in the <code>/usr/openwin</code> subtree of the file system.
SPOOLEDSIZE*	The space used by the spooled version of this package. This is used during the setup of a server by the initial system installation programs.

All sizes are specified in bytes. Default disk partitions and file system sizes are derived from the values provided: accuracy is important.

EXAMPLES

EXAMPLE 1 A sample `.packagetoc` file.

The following is an example package entry in a `.packagetoc` file.

```
#ident "@(#)packagetoc.4 1.2 92/04/28"
PKG=SUNWaccr
PKGDIR=SUNWaccr
NAME=System Accounting, (Root)
VENDOR=Sun Microsystems, Inc.
VERSION=8.1
PRODNAME=SunOS
PRODVERS=5.0beta2
SUNW_PKGTYPE=root
```

EXAMPLE 1 A sample .packagetoc file. (Continued)

```
ARCH=sparc
DESC=System Accounting, (Root)
BASEDIR=/
CATEGORY=system
ROOTSIZE=11264
VARSIZE= 15360
OPTSIZE=0
EXPORTSIZE=0
USRSIZE=0
USROWNSIZE=0
```

SEE ALSO cdtoc(4), clustertoc(4), depend(4), order(4), pkginfo(4), pkgmap(4)

NOTES The parameters NAME, VENDOR, VERSION, PRODNAME, PRODVERS, SUNW_PKGTYPE, SUNW_LOC, SUNW_PKGLIST, ARCH, DESC, BASEDIR, and CATEGORY are assumed to have been taken directly from the package's pkginfo(4) file. The length and formatting restrictions placed on the values for these parameters are identical to those for the corresponding entries in the pkginfo(4) file.

The value specified for the parameter PKGDIR should not exceed 255 characters.

The value specified for the parameters ROOTSIZE, VARSIZE, OPTSIZE, EXPORTSIZE, USRSIZE and USROWNSIZE must be a single integer value. The values can be derived from the package's pkgmap file by counting all space consumed by any files installed in the applicable file system. The space includes that used for directory entries and any UFS overhead that exists because of the way the files are represented (directory allocation scheme; direct, indirect, double indirect blocks; fragments; etc.)

The following kinds of entries in the pkgmap(4) file should be included in the space derivation:

f	regular file
c	character special file
b	block special file
p	pipe
l	hard link
s	symbolic link
x, d	directory
i	packaging installation script or information file (<i>copyright, depend, postinstall, postremove</i>)

packingrules(4)

NAME	packingrules – packing rules file for cachefs and filesync						
SYNOPSIS	<code>\$HOME/.packingrules</code>						
DESCRIPTION	<p><code>\$HOME/.packingrules</code> is a packing rules file for <code>filesync</code> and <code>cachefspack</code>. <code>\$HOME/.packingrules</code> contains a list of directories and files that are to be packed and synchronized. It also contains a list of directories and files that are to be specifically excluded from packing and synchronization. See <code>filesync(1)</code> and <code>cachefspack(1M)</code>.</p> <p>The <code>\$HOME/.packingrules</code> file is automatically created if users invoke <code>filesync</code> with filename arguments. By using <code>filesync</code> options, users can augment the packing rules in <code>\$HOME/.packingrules</code>.</p> <p>Many users choose to manually create the packing rules file and edit it by hand. Users can edit <code>\$HOME/.packingrules</code> (using any editor) to permanently change the <code>\$HOME/.packingrules</code> file, or to gain access to more powerful options that are not available from the command line (such as <code>IGNORE</code> commands). It is much easier to enter complex wildcard expressions by editing the <code>\$HOME/.packingrules</code> file.</p> <p>Blank lines and lines that begin with a pound sign (<code>#</code>) are ignored.</p> <p>Any line can be continued by placing a backslash (<code>\</code>) immediately before the NEWLINE.</p> <p>All other lines in the <code>\$HOME/.packingrules</code> file have one of the following formats:</p> <table><tr><td><code>PACKINGRULES</code></td><td><i>major</i>. <i>minor</i>. This line is not actually required, but it should be the first line of every packing rules file. This line identifies the packing rules file for the <code>file(1)</code> command and specifies a format version number. The current version number is 1.1. See <code>file(1)</code>.</td></tr><tr><td><code>BASE <i>directory-1</i> [<i>directory-2</i>]</code></td><td>This line identifies a directory (or pair of directories) under which files should be packed and synchronized. At least one directory name must be specified. For rules that are to be used by <code>filesync</code> a second directory name (where the copies are to be kept) must also be specified. The arguments must be fully qualified path names, and may include environment variables.</td></tr><tr><td><code>LIST <i>name</i> ...</code></td><td>This line enumerates a list of files and sub-directories (beneath the current <code>BASE</code>) that are to be kept synchronized. This specification is recursive, in that specifying the name of a directory automatically</td></tr></table>	<code>PACKINGRULES</code>	<i>major</i> . <i>minor</i> . This line is not actually required, but it should be the first line of every packing rules file. This line identifies the packing rules file for the <code>file(1)</code> command and specifies a format version number. The current version number is 1.1. See <code>file(1)</code> .	<code>BASE <i>directory-1</i> [<i>directory-2</i>]</code>	This line identifies a directory (or pair of directories) under which files should be packed and synchronized. At least one directory name must be specified. For rules that are to be used by <code>filesync</code> a second directory name (where the copies are to be kept) must also be specified. The arguments must be fully qualified path names, and may include environment variables.	<code>LIST <i>name</i> ...</code>	This line enumerates a list of files and sub-directories (beneath the current <code>BASE</code>) that are to be kept synchronized. This specification is recursive, in that specifying the name of a directory automatically
<code>PACKINGRULES</code>	<i>major</i> . <i>minor</i> . This line is not actually required, but it should be the first line of every packing rules file. This line identifies the packing rules file for the <code>file(1)</code> command and specifies a format version number. The current version number is 1.1. See <code>file(1)</code> .						
<code>BASE <i>directory-1</i> [<i>directory-2</i>]</code>	This line identifies a directory (or pair of directories) under which files should be packed and synchronized. At least one directory name must be specified. For rules that are to be used by <code>filesync</code> a second directory name (where the copies are to be kept) must also be specified. The arguments must be fully qualified path names, and may include environment variables.						
<code>LIST <i>name</i> ...</code>	This line enumerates a list of files and sub-directories (beneath the current <code>BASE</code>) that are to be kept synchronized. This specification is recursive, in that specifying the name of a directory automatically						

packingrules(4)

includes all files and subdirectories it contains. Regular expressions (as described in `glob` and `gmatch`) are permitted. See `glob(1)` and `gmatch(3GEN)`.

IGNORE *name* ...

This line enumerates a list of files that are not to be kept synchronized. Regular expressions (using `glob` and `gmatch`) are permitted.

There are important differences between the arguments to `LIST` and `IGNORE` statements. The arguments to a `LIST` statement can contain slashes and are interpreted as file names relative to the `BASE` directories. The arguments to an `IGNORE` statement are simpler names or expressions that cannot contain slashes. An `IGNORE` statement will not override a `LIST` statement. `IGNORE` statements only exclude files that are found beneath `LISTed` directories.

If the first name argument to a `LIST` statement begins with an exclamation point ('!'), the remainder of the statement will be executed as a command. The command will be run in the current `BASE` directory. The output of the command will be treated as a list of newline separated file names to be packed/synchronized. The resulting file names will be interpreted relative to the enclosing `BASE` directory.

If the first name argument to an `IGNORE` statement begins with an exclamation point ('!'), the remainder of the statement will be executed as a command. The command will be run in the current `BASE` directory. The command will be expected to figure out which names should not be synchronized. The output of the command will be treated as a list of newline separated file names that should be excluded from the packing and synchronization list.

Commands will be broken into distinct arguments and run directly with `sh -c`. Blanks can be embedded in an argument by escaping them with a backslash ('\') or enclosing the argument in double quotes ('"'). Double quotes can be passed in arguments by escaping the double quotes with a backslash ('\').

`LIST` lines only apply to the `BASE` statement that precedes them. `IGNORE` lines can appear before any `BASE` statement (in which case they apply to all `BASEs`) or after a `BASE` statement (in which case they only apply to the `BASE` that precedes them). Any number of these statements can occur in any combination. The order is not important.

EXAMPLES

EXAMPLE 1 A sample `$HOME.packingrules` file.

The use of these statements is illustrated in the following `$HOME.packingrules` file.

```
#
# junk files, not worth copying
#
IGNORE core *.o *.bak *%
#
# most of the stuff I want to keep in sync is in my $HOME
#
```

packingrules(4)

EXAMPLE 1 A sample `$HOME.packingrules` file. (Continued)

```
BASE /net/bigserver/export/home/myname $HOME
# everything in my work sub-directory should be maintained
LIST work
# a few of my favorite mail boxes should be replicated
LIST m/incoming
LIST m/action
LIST m/pending
#
# I like to carry around a couple of project directories
# but skip all the postscript output
#
BASE /net/bigserver/export/projects $HOME/projects
LIST poindexter epiphany
IGNORE *.ps
#
# the foonly package should always be kept on every machine
#
BASE /net/bigserver/opt/foonly /opt/foonly
LIST !cat .packinglist
#
# and the latest executables for the standard build environment
#
BASE /net/bigserver/export/buildenv $HOME/buildenv
LIST !find . -type f -a -perm -111 -a -print
```

SEE ALSO file(1), filesync(1), cachefspack(1M)

NAME	pam.conf – configuration file for pluggable authentication modules
SYNOPSIS	<code>/etc/pam.conf</code>
DESCRIPTION	<p><code>pam.conf</code> is the configuration file for the Pluggable Authentication Module architecture, or PAM. A PAM module provides functionality for one or more of four possible services: authentication, account management, session management, and password management. An authentication service module provides functionality to authenticate a user and set up user credentials. An account management module provides functionality to determine if the current user's account is valid. This includes checking for password and account expiration, as well as verifying access hour restrictions. A session management module provides functionality to set up and terminate login sessions. A password management module provides functionality to change a user's authentication token or password. Each of the four service modules can be implemented as a shared library object which can be referenced in the <code>pam.conf</code> configuration file.</p> <p>The <code>pam.conf</code> file contains a listing of services. Each service is paired with a corresponding service module. When a service is requested, its associated module is invoked. Each entry has the following format:</p> <pre><i>service_name module_type control_flag module_path options</i></pre> <p>Below is an example of the <code>pam.conf</code> configuration file with support for authentication, account management, and session management modules.</p> <pre>login auth required /usr/lib/security/\$ISA/pam_unix.so.1 debug login session required /usr/lib/security/\$ISA/pam_unix.so.1 login account required /usr/lib/security/\$ISA/pam_unix.so.1 telnet session required /usr/lib/security/\$ISA/pam_unix.so.1 other auth required /usr/lib/security/\$ISA/pam_unix.so.1 other passwd required /usr/lib/security/\$ISA/pam_unix.so.1</pre> <p>The <i>service_name</i> denotes the service (for example, <code>login</code>, <code>dtlogin</code>, or <code>rlogin</code>). The keyword, <i>other</i>, indicates the module all other applications which have not been specified should use. The <i>other</i> keyword can also be used if all services of the same <i>module_type</i> have the same requirements. In the example above, since all of the services use the same session module, they could have been replaced by a single <i>other</i> line.</p> <p><i>module_type</i> denotes the service module type: authentication (<i>auth</i>), account management (<i>account</i>), session management (<i>session</i>), or password management (<i>password</i>).</p> <p>The <i>control_flag</i> field determines the behavior of stacking, and will be discussed in more detail below.</p> <p>The <i>module_path</i> field specifies the pathname to a shared library object which implements the service functionality. If the pathname is not absolute, it is assumed to be relative to <code>/usr/lib/security/\$ISA/</code>. If the pathname contains the <code>\$ISA</code></p>
Simplified PAM.CONF configuration file	

pam.conf(4)

**Integrating
Multiple
Authentication
Services With
Stacking**

token, that token is replaced by an implementation defined directory name which defines the path relative to the calling program's instruction set architecture.

The *options* field is used by the PAM framework layer to pass module specific options to the modules. It is up to the module to parse and interpret the options. This field can be used by the modules to turn on debugging or to pass any module specific parameters such as a TIMEOUT value. It can also be used to support unified login. The options supported by the modules are documented in their respective manual pages. For example, `pam_unix(5)` lists the options accepted by the UNIX module.

When a service_name of the same *module_type* is defined more than once, the service is said to be *stacked*. Each module referenced in the *module_path* for that service is then processed in the order that it occurs in the configuration file. The *control_flag* field specifies the continuation and failure semantics of the modules, and may be *requisite*, *required*, *optional*, or *sufficient*.

The PAM framework processes each service module in the stack. If all *requisite* and *required* modules in the stack succeed, then success is returned, and *optional* and *sufficient* error values are ignored. If one or more *requisite* or *required* modules fail, then the error value from the first *requisite* or *required* module that failed is returned.

If none of the service modules in the stack are designated as *requisite* or *required*, then the PAM framework requires that at least one *optional* or *sufficient* module succeed. If all fail then the error value from the first service module in the stack is returned.

The *requisite* and *sufficient* flags cause two exceptions to the above semantics. If a service module that is designated as *requisite* fails, then the PAM framework immediately returns an error to the application, and all subsequent service modules in the stack are ignored. If a prior *required* service module has failed, then that error is returned. If no prior *required* service module failed, then the error from the failed *requisite* service module is returned.

If a service module that is designated as *sufficient* succeeds, then the PAM framework immediately returns success to the application, and all subsequent services modules in the stack, even *requisite* and *required* ones, are ignored, given that all prior *requisite* and *required* modules have also succeeded. If a prior *required* module has failed, then the error value from that module is returned.

If any entry in `pam.conf` is incorrect, or if a module does not exist or cannot be opened, then all PAM services will fail and users will not be permitted access to the system. An error will be logged through `syslog(3C)` at the `LOG_CRIT` level. To fix incorrect entries in `pam.conf`, a system administrator may boot the system in maintenance mode (single user) to edit the file. Below is a sample configuration file that stacks the `su`, `login`, and `rlogin` services.

```
su    auth  requisite  /usr/lib/security/$ISA/pam_inhouse.so.1
su    auth  required   /usr/lib/security/$ISA/pam_unix.so.1      debug
login auth  required   /usr/lib/security/$ISA/pam_unix.so.1      debug
login auth  optional   /usr/lib/security/$ISA/pam_inhouse.so.1
rlogin auth sufficient /usr/lib/security/$ISA/pam_rhosts_auth.so.1
```

```
rlogin auth required /usr/lib/security/$ISA/pam_unix.so.1
```

In the case of `su`, the user is authenticated by the Inhouse and UNIX authentication modules. Because the Inhouse and UNIX authentication modules are *requisite* and *required*, respectively, an error is returned back to the application if either module fails. In addition, if the *requisite* authentication (Inhouse authentication) fails, the UNIX authentication module is never invoked, and the error is returned immediately back to the application.

In the case of `login`, the *required* keyword for *control_flag* requires that the user be allowed to login only if the user is authenticated by the UNIX service module. If UNIX authentication fails, control continues to proceed down the stack, and the Inhouse authentication module is invoked. Inhouse authentication is optional by virtue of the *optional* keyword in the *control_flag* field. The user can still log in even if Inhouse authentication fails, assuming the UNIX authentication succeeded.

In the case of `rlogin`, the *sufficient* keyword for *control_flag* specifies that if the *rhosts* authentication check succeeds, then PAM should return success to `rlogin` and `rlogin` should not prompt the user for a password. The UNIX authentication module, which is the next module in the stack, will only be invoked if the *rhosts* check fails. This gives the system administrator the flexibility to determine if *rhosts* alone is sufficient enough to authenticate a remote user.

Some modules may return PAM_IGNORE in certain situations. In these cases the PAM framework ignores the entire entry in `pam.conf` regardless of whether or not it is *requisite*, *required*, *optional* or *sufficient*.

Utilities and Files

A following is a list of the utilities that are known to use PAM: include: `login`, `passwd`, `su`, `rlogind`, `rshd`, `telnetd`, `ftpd`, `rpc.rexd`, `uucpd`, `init`, `sac`, and `ttymon`.

The utility `dtlogin` also uses PAM. Note however that `dtlogin` is the login service utility for the Common Desktop Environment (CDE).

The PAM configuration file does not dictate either the name or the location of the service specific modules. The convention, however, is the following:

```
/usr/lib/security/$ISA/pam_module_name.so.x
```

Implements various function of specific authentication services.

```
/etc/pam.conf
```

Configuration file.

```
/usr/lib/$ISA/libpam.so.1
```

Implements the PAM framework library.

EXAMPLES

EXAMPLE 1 A sample `pam.conf` configuration file.

The following is a sample `pam.conf` configuration file. Lines that begin with the `#` symbol are treated as comments, and therefore ignored.

pam.conf(4)

EXAMPLE 1 A sample pam.conf configuration file. (Continued)

```
#
# PAM configuration

#
# Authentication management for login service is stacked.
# Both UNIX and inhouse authentication functions are invoked.
login  auth  required  /usr/lib/security/$ISA/pam_unix.so.1
login  auth  required  /usr/lib/security/$ISA/pam_inhouse.so.1 try_first_pass
dtlogin auth  required  /usr/lib/security/$ISA/pam_unix.so.1
dtlogin auth  required  /usr/lib/security/$ISA/pam_inhouse.so.1 try_first_pass
#
# Authentication management for rlogin service is stacked.
# If the rhost check succeeds, do not continue
rlogin auth  sufficient /usr/lib/security/$ISA/pam_rhosts_auth.so.1
rlogin auth  required   /usr/lib/security/$ISA/pam_unix.so.1
#
# Other services use UNIX authentication
other  auth  required   /usr/lib/security/$ISA/pam_unix.so.1
#
# Account management for login service is stacked.
# UNIX account management is required
# Inhouse account management is optional
login  account  required  /usr/lib/security/$ISA/pam_unix.so.1
login  account  optional  /usr/lib/security/$ISA/pam_inhouse.so.1
dtlogin account  required  /usr/lib/security/$ISA/pam_unix.so.1
dtlogin account  optional  /usr/lib/security/$ISA/pam_inhouse.so.1
other  account  required  /usr/lib/security/$ISA/pam_unix.so.1
#
# Session management
other  session  required  /usr/lib/security/$ISA/pam_unix.so.1
#
# Password management
other  password  required  /usr/lib/security/$ISA/pam_unix.so.1
```

ATTRIBUTES See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

NOTES The interfaces in libpam() are MTsafe only if each thread within the multi-threaded application uses its own PAM handle.

NAME	passwd – password file														
SYNOPSIS	/etc/passwd														
DESCRIPTION	<p>The file /etc/passwd is a local source of information about users' accounts. The password file can be used in conjunction with other password sources, such as the NIS maps passwd.byname and passwd.bygid and the NIS+ table passwd. Programs use the getpwnam(3C) routines to access this information.</p> <p>Each passwd entry is a single line of the form:</p> <pre>username:password:uid: gid:gcos-field:home-dir: login-shell</pre> <p>where</p> <table> <tr> <td><i>username</i></td> <td>is the user's login name. It is recommended that this field conform to the checks performed by pwck(1M).</td> </tr> <tr> <td><i>password</i></td> <td>is an empty field. The encrypted password for the user is in the corresponding entry in the /etc/shadow file. pwconv(1M) relies on a special value of 'x' in the password field of /etc/passwd. If this value of 'x' exists in the password field of /etc/passwd, this indicates that the password for the user is already in /etc/shadow and should not be modified.</td> </tr> <tr> <td><i>uid</i></td> <td>is the user's unique numerical ID for the system.</td> </tr> <tr> <td><i>gid</i></td> <td>is the unique numerical ID of the group that the user belongs to.</td> </tr> <tr> <td><i>gcos-field</i></td> <td>is the user's real name, along with information to pass along in a mail-message heading. (It is called the gcos-field for historical reasons.) An "&" (ampersand) in this field stands for the login name (in cases where the login name appears in a user's real name).</td> </tr> <tr> <td><i>home-dir</i></td> <td>is the pathname to the directory in which the user is initially positioned upon logging in.</td> </tr> <tr> <td><i>login-shell</i></td> <td>is the user's initial shell program. If this field is empty, the default shell is /usr/bin/sh.</td> </tr> </table> <p>The maximum value of the <i>uid</i> and <i>gid</i> fields is 2147483647. To maximize interoperability and compatibility, administrators are recommended to assign users a range of UIDs and GIDs below 60000 where possible.</p> <p>The password file is an ASCII file. Because the encrypted passwords are always kept in the shadow file, /etc/passwd has general read permission on all systems and can be used by routines that map between numerical user IDs and user names.</p>	<i>username</i>	is the user's login name. It is recommended that this field conform to the checks performed by pwck(1M).	<i>password</i>	is an empty field. The encrypted password for the user is in the corresponding entry in the /etc/shadow file. pwconv(1M) relies on a special value of 'x' in the password field of /etc/passwd. If this value of 'x' exists in the password field of /etc/passwd, this indicates that the password for the user is already in /etc/shadow and should not be modified.	<i>uid</i>	is the user's unique numerical ID for the system.	<i>gid</i>	is the unique numerical ID of the group that the user belongs to.	<i>gcos-field</i>	is the user's real name, along with information to pass along in a mail-message heading. (It is called the gcos-field for historical reasons.) An "&" (ampersand) in this field stands for the login name (in cases where the login name appears in a user's real name).	<i>home-dir</i>	is the pathname to the directory in which the user is initially positioned upon logging in.	<i>login-shell</i>	is the user's initial shell program. If this field is empty, the default shell is /usr/bin/sh.
<i>username</i>	is the user's login name. It is recommended that this field conform to the checks performed by pwck(1M).														
<i>password</i>	is an empty field. The encrypted password for the user is in the corresponding entry in the /etc/shadow file. pwconv(1M) relies on a special value of 'x' in the password field of /etc/passwd. If this value of 'x' exists in the password field of /etc/passwd, this indicates that the password for the user is already in /etc/shadow and should not be modified.														
<i>uid</i>	is the user's unique numerical ID for the system.														
<i>gid</i>	is the unique numerical ID of the group that the user belongs to.														
<i>gcos-field</i>	is the user's real name, along with information to pass along in a mail-message heading. (It is called the gcos-field for historical reasons.) An "&" (ampersand) in this field stands for the login name (in cases where the login name appears in a user's real name).														
<i>home-dir</i>	is the pathname to the directory in which the user is initially positioned upon logging in.														
<i>login-shell</i>	is the user's initial shell program. If this field is empty, the default shell is /usr/bin/sh.														

passwd(4)

Blank lines are treated as malformed entries in the `passwd` file and cause consumers of the file, such as `getpwnam(3C)`, to fail.

Previous releases used a password entry beginning with a '+' (plus sign) or '-' (minus sign) to selectively incorporate entries from NIS maps for password. If still required, this is supported by specifying "passwd : compat" in `nsswitch.conf(4)`. The "compat" source might not be supported in future releases. The preferred sources are files followed by the identifier of a name service, such as `nis` or `ldap`. This has the effect of incorporating the entire contents of the name service's `passwd` database after the `passwd` file.

EXAMPLES

EXAMPLE 1 Sample passwd File

Here is a sample `passwd` file:

```
root:g.mJzTnu8icF.:0:10:God:/:/bin/csh
fred:6k/7KCFRPNVXg:508:10:& Fredericks:/usr2/fred:/bin/csh
```

and the sample password entry from `nsswitch.conf`:

```
passwd: files nisplus
```

In this example, there are specific entries for users `root` and `fred` to assure that they can login even when the system is running single-user. In addition, anyone in the NIS+ table `passwd` will be able to login with their usual password, shell, and home directory.

If the password file is:

```
root:g.mJzTnu8icF.:0:10:God:/:/bin/csh
fred:6k/7KCFRPNVXg:508:10:& Fredericks:/usr2/fred:/bin/csh
+
```

and the password entry from `nsswitch.conf` is:

```
passwd: compat
```

then all the entries listed in the NIS `passwd.byuid` and `passwd.byname` maps will be effectively incorporated after the entries for `root` and `fred`.

FILES

```
/etc/nsswitch.conf
/etc/passwd
/etc/shadow
```

System Administration Guide: Basic Administration

pathalias(4)

NAME	pathalias – alias file for FACE
SYNOPSIS	<code>/usr/vmsys/pathalias</code>
DESCRIPTION	<p>The <code>pathalias</code> files contain lines of the form <code>alias=path</code> where <i>path</i> can be one or more colon-separated directories. Whenever a FACE (Framed Access Command Environment, see <code>face(1)</code>) user references a path not beginning with a <code>"/</code>, this file is checked. If the first component of the pathname matches the left-hand side of the equals sign, the right-hand side is searched much like <code>\$PATH</code> variable in the system. This allows users to reference the folder <code>\$HOME/FILECABINET</code> by typing <code>filecabinet</code>.</p> <p>There is a system-wide <code>pathalias</code> file called <code>\$VMSYS/pathalias</code>, and each user can also have local alias file called <code>\$HOME/pref/pathalias</code>. Settings in the user alias file override settings in the system-wide file. The system-wide file is shipped with several standard FACE aliases, such as <code>filecabinet</code>, <code>wastebasket</code>, <code>preferences</code>, <code>other_users</code>, etc.</p>
FILES	<code>\$HOME/pref/pathalias</code> <code>\$VMSYS/pathalias</code>
SEE ALSO	<code>face(1)</code>
NOTES	Unlike command keywords, partial matching of a path alias is not permitted, however, path aliases are case insensitive. The name of an alias should be alphabetic, and in no case can it contain special characters like <code>"/</code> , <code>"\"</code> , or <code>"=</code> ". There is no particular limit on the number of aliases allowed. Alias files are read once, at login, and are held in core until logout. Thus, if an alias file is modified during a session, the change will not take effect until the next session.

NAME	path_to_inst – device instance number file
SYNOPSIS	/etc/path_to_inst
DESCRIPTION	<p>/etc/path_to_inst records mappings of physical device names to instance numbers.</p> <p>The instance number of a device is encoded in its minor number, and is the way that a device driver determines which of the possible devices that it may drive is referred to by a given special file.</p> <p>In order to keep instance numbers persistent across reboots, the system records them in /etc/path_to_inst.</p> <p>This file is read only at boot time, and is updated by add_drv(1M) and drvconfig(1M).</p> <p>Note that it is generally not necessary for the system administrator to change this file, as the system will maintain it.</p> <p>The system administrator can change the assignment of instance numbers by editing this file and doing a reconfiguration reboot. However, any changes made in this file will be lost if add_drv(1M) or drvconfig(1M) is run before the system is rebooted.</p> <p>Each instance entry is a single line of the form:</p> <pre>"physical name" instance number "driver binding name"</pre> <p>where</p> <p><i>physical name</i> is the absolute physical pathname of a device. This pathname must be enclosed in double quotes.</p> <p><i>instance number</i> is a decimal or hexadecimal number.</p> <p><i>driver binding name</i> is the name used to determine the driver for the device. This name may be a driver alias or a driver name. The driver binding name must be enclosed in double quotes.</p>
EXAMPLES	<p>EXAMPLE 1 Sample path_to_inst Entries</p> <p>Here are some sample path_to_inst entries:</p> <pre>"/iommuf,e0000000" 0 "iommuf" "/iommuf,e0000000/sbus@f,e0001000" 0 "sbus" "/iommuf,e0000000/sbus@f,e0001000/sbusmem@e,0" 14 "sbusmem" "/iommuf,e0000000/sbus@f,e0001000/sbusmem@f,0" 15 "sbusmem" "/iommuf,e0000000/sbus@f,e0001000/ledma@f,400010" 0 "ledma" "/obio/serial@0,100000" 0 "zs" "/SUNW,sx@f,80000000" 0 "SUNW,sx"</pre>

path_to_inst(4)

EXAMPLE 1 Sample path_to_inst Entries (Continued)

FILES /etc/path_to_inst

SEE ALSO add_drv(1M), boot(1M), drvconfig(1M), mknod(1M)

WARNINGS If the file is removed the system may not be bootable (as it may rely on information found in this file to find the root, usr or swap device). If it does successfully boot, it will regenerate the file, but after rebooting devices may end up having different minor numbers than they did before, and special files created via mknod(1M) may refer to different devices than expected.

For the same reasons, changes should not be made to this file without careful consideration.

NOTES This document does not constitute an API. path_to_inst may not exist or may have a different content or interpretation in a future release. The existence of this notice does not imply that any other documentation that lacks this notice constitutes an API.

NAME	pci – configuration files for PCI device drivers																		
DESCRIPTION	<p>The Peripheral Component Interconnect (PCI) bus is a little endian bus. PCI devices are <i>self-identifying</i> — that is to say the PCI device provides configuration parameters to the system, which allows the system to identify the device and its driver. The configuration parameters are represented in the form of name-value pairs that can be retrieved using the DDI property interfaces. See <code>ddi_prop_lookup(9F)</code> for details.</p> <p>The PCI bus properties are derived from PCI configuration space, or supplied by the Fcode PROM, if it exists. Therefore, driver configuration files are not necessary for these devices.</p> <p>On some occasions, drivers for PCI devices can use driver configuration files to provide driver private properties through the global property mechanism. See <code>driver.conf(4)</code> for further details. Driver configuration files can also be used to augment or override properties for a specific instance of a driver.</p> <p>All bus drivers of class <code>pci</code> recognize the following properties:</p> <p><code>reg</code> An arbitrary length array where each element of the array consists of a 5-tuple of 32-bit values. Each array element describes a logically contiguous mappable resource on the PCI bus.</p> <p>The first three values in the 5-tuple describe the PCI address of the mappable resource. The first tuple contains the following information:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td style="padding: 2px;">Bits 0 - 7</td> <td style="padding: 2px;">8-bit register number</td> </tr> <tr> <td style="padding: 2px;">Bits 8 - 10</td> <td style="padding: 2px;">3-bit function number</td> </tr> <tr> <td style="padding: 2px;">Bits 11 - 15</td> <td style="padding: 2px;">5-bit device number</td> </tr> <tr> <td style="padding: 2px;">Bits 16 - 23</td> <td style="padding: 2px;">8-bit bus number</td> </tr> <tr> <td style="padding: 2px;">Bits 24 - 25</td> <td style="padding: 2px;">2-bit address space type identifier</td> </tr> </table> <p>The address space type identifier can be interpreted as follows:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td style="padding: 2px;">0x0</td> <td style="padding: 2px;">configuration space</td> </tr> <tr> <td style="padding: 2px;">0x1</td> <td style="padding: 2px;">I/O space</td> </tr> <tr> <td style="padding: 2px;">0x2</td> <td style="padding: 2px;">32-bit memory space address</td> </tr> <tr> <td style="padding: 2px;">0x3</td> <td style="padding: 2px;">64-bit memory space address</td> </tr> </table>	Bits 0 - 7	8-bit register number	Bits 8 - 10	3-bit function number	Bits 11 - 15	5-bit device number	Bits 16 - 23	8-bit bus number	Bits 24 - 25	2-bit address space type identifier	0x0	configuration space	0x1	I/O space	0x2	32-bit memory space address	0x3	64-bit memory space address
Bits 0 - 7	8-bit register number																		
Bits 8 - 10	3-bit function number																		
Bits 11 - 15	5-bit device number																		
Bits 16 - 23	8-bit bus number																		
Bits 24 - 25	2-bit address space type identifier																		
0x0	configuration space																		
0x1	I/O space																		
0x2	32-bit memory space address																		
0x3	64-bit memory space address																		

pci(4)

The bus number is a unique identifying number assigned to each PCI bus within a PCI domain.

The device number is a unique identifying number assigned to each PCI device on a PCI bus. Note that a device number is unique only within the set of device numbers for a particular bus.

Each PCI device can have one to eight logically independent functions, each with its own independent set of configuration registers. Each function on a device is assigned a function number. For a PCI device with only one function, the function number must be 0.

The register number field selects a particular register within the set of configuration registers corresponding to the selected function.

The second and third values in the `reg` property 5-tuple specify the 64-bit address of the mappable resource within the PCI address domain. The second 32-bit tuple corresponds to the high order four bytes of the 64-bit address. The third 32-bit tuple corresponds to the low order bytes.

The fourth and fifth 32-bit values in the 5-tuple `reg` property specify the size of the mappable resource. The size is a 64-bit value, where the fourth tuple corresponds to the high order bytes of the 64-bit size and the fifth corresponds to the low order.

The driver can refer to the elements of this array by index, and construct kernel mappings to these addresses using `ddi_regs_map_setup(9F)`. The index into the array is passed as the *number* argument of `ddi_regs_map_setup(9F)`.

At a high-level interrupt context, you can use the `ddi_get*` and `ddi_put*` family of functions to access I/O and memory space. However, access to configuration space is not allowed when running at a high-interrupt level.

`interrupts`

This property consists of a single-integer element array. Valid interrupt property values are 1, 2, 3, and 4. This value is derived directly from the contents of the device's configuration-interrupt-pin register.

A driver should use an index value of 0 when registering its interrupt handler with `ddi_add_intr(9F)`.

All PCI devices support the `reg` property. The device number and function number as derived from the `reg` property are used to construct the address part of the device name under `/devices`.

Only devices that generate interrupts support an `interrupts` property.

Occasionally it might be necessary to override or augment the configuration information supplied by a PCI device. This change can be achieved by writing a driver configuration file that describes a prototype device node specification containing the additional properties required.

For the system to merge the prototype node specification into an actual device node, certain conditions must be met.

- First, the name property must be identical. The value of the name property needs to match the binding name of the device. The binding name is the name chosen by the system to bind a driver to a device and is either an alias associated with the driver or the hardware node name of the device.
- Second, the parent property must identify the PCI bus.
- Third, the unit-address property must identify the card. The format of the unit-address property is:

DD [, F]

where DD is the device number and F is the function number. If the function number is 0, only DD is specified.

EXAMPLES **EXAMPLE 1** A sample configuration file.

An example configuration file called ACME, *scsi-hba.conf* for a PCI driver called ACME, *scsi-hba* follows:

```
#
# Copyright (c) 1995, ACME SCSI Host Bus Adaptor
# ident    "@(#)ACME,scsi-hba.conf 1.1 96/02/04"
name="ACME,scsi-hba" parent="/pci@1,0/pci@1f,4000"
    unit-address="3" scsi-initiator-id=6;
hba-advanced-mode="on";
hba-dma-speed=10;
```

In this example, a property *scsi-initiator-id* specifies the SCSI bus initiator id that the adapter should use, for just one particular instance of adapter installed in the machine. The name property identifies the driver and the parent property to identify the particular bus the card is plugged into. This example uses the parent's full path name to identify the bus. The unit-address property identifies the card itself, with device number of 3 and function number of 0.

Two global driver properties are also created: *hba-advanced-mode* (which has the string value *on*) and *hba-dma-speed* (which has the value 10 M bit/s). These properties apply to all device nodes of the ACME, *scsi-hba*. The following is an example configuration file called ACME, *foo.conf* for a PCI driver called ACME, *foo*;

```
#
# Copyright (c) 1996, ACME Foo driver
# ident    "@(#)ACME,foo.conf 1.1 95/11/14"
```

pci(4)

EXAMPLE 1 A sample configuration file. *(Continued)*

```
name="ACME,foo" class="pci" unit-address="3,1"
  debug-mode=12;
```

In this example, we provide a property `debug-mode` for all instances of the `ACME,foo` driver with parents of class `pci` and device and function numbers of 3 and 1, respectively.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Writing Device Drivers

IEEE 1275 PCI Bus Binding

NAME	pcmcia – PCMCIA nexus driver
DESCRIPTION	The PCMCIA nexus driver supports PCMCIA card client device drivers. There are no user-configurable options for this driver.
FILES	/kernel/misc/pcmcia pcmcia driver
SEE ALSO	pcmciaad(1M)

phones(4)

NAME	phones – remote host phone number database
SYNOPSIS	/etc/phones
DESCRIPTION	<p>The file /etc/phones contains the system-wide private phone numbers for the tip(1) program. /etc/phones is normally unreadable, and so may contain privileged information. The format of /etc/phones is a series of lines of the form:</p> <pre><system-name> [\t] * <phone-number> .</pre> <p>The system name is one of those defined in the remote(4) file and the phone number is constructed from [0123456789-=%]. The '=' and '*' characters are indicators to the auto call units to pause and wait for a second dial tone (when going through an exchange). The '=' is required by the DF02-AC and the '*' is required by the BIZCOMP 1030.</p> <p>Comment lines are lines containing a '#' sign in the first column of the line.</p> <p>Only one phone number per line is permitted. However, if more than one line in the file contains the same system name tip(1) will attempt to dial each one in turn, until it establishes a connection.</p>
FILES	/etc/phones
SEE ALSO	tip(1), remote(4)

NAME	pkginfo – package characteristics file
DESCRIPTION	<p>pkginfo is an ASCII file that describes the characteristics of the package along with information that helps control the flow of installation. It is created by the software package developer.</p> <p>Each entry in the pkginfo file is a line that establishes the value of a parameter in the following form:</p> <pre>PARAM= "value"</pre> <p>There is no required order in which the parameters must be specified within the file. Each parameter is described below. Only fields marked with an asterisk are mandatory.</p> <p>PKG* Abbreviation for the package being installed. All characters in the abbreviation must be alphanumeric and the first may not be numeric. The abbreviation is limited to a maximum length of 32 characters. <code>install</code>, <code>new</code>, and <code>all</code> are reserved abbreviations. It is customary to make the first four letters unique to your company, such as the company's stock symbol.</p> <p>NAME* Text that specifies the package name (maximum length of 256 ASCII characters). Use the <code>NAME</code> parameter as the foundation for describing the functionality and purpose of the package; spell out any acronyms and avoid internal product/project code names. The <code>DESC</code> parameter can then be used to expand the descriptive information. Use the <code>NAME</code> parameter to state as specifically as possible the use of the package, why a user would need to load it, and so on.</p> <p>ARCH* A comma-separated list of alphanumeric tokens that indicate the architecture associated with the package. The <code>pkgmk(1)</code> tool may be used to create or modify this value when actually building the package. The maximum length of a token is 16 characters and it cannot include a comma.</p> <p>Solaris's installation software meaningfully uses only one architecture token of the form:</p> <pre><instruction_set_architecture> [. <platform_group>]</pre> <p>where <i>platform_group</i> is intended only for Solaris installation packages. Third party application software should restrict itself to <code>ARCH</code> values from the following Solaris-supported instruction set architectures (<code>uname -p</code>): <code>sparc</code>, <code>i386</code>, and <code>ppc</code>. Examples of Solaris' platform groups (<code>uname -m</code>) are <code>sun4u</code>, <code>sun4d</code>, and</p>

pkginfo(4)

	<p>sun4m for the SPARC® instruction set and i86pc for the i386 instruction set. See <code>uname(1)</code> and <code>isalist(1)</code> for more details.</p>
VERSION*	<p>Text that specifies the current version associated with the software package. The maximum length is 256 ASCII characters and the first character cannot be a left parenthesis. The <code>pkgmk(1)</code> tool may be used to create or modify this value when actually building the package. Current Solaris software practice is to assign this parameter monotonically increasing Dewey decimal values of the form:</p> <p><i><major_revision> . <minor_revision> [. <micro_revision>]</i></p> <p>where all the revision fields are integers. The versioning fields can be extended to an arbitrary string of numbers in Dewey-decimal format, if necessary.</p>
CATEGORY*	<p>A comma-separated list of categories under which a package may be displayed. A package must at least belong to the system or application category. Categories are case-insensitive and may contain only alphanumeric characters. Each category is limited in length to 16 characters.</p>
DESC	<p>Text that describes the package (maximum length of 256 ASCII characters). This parameter value is used to provide the installer with a description of what the package contains and should build on the description provided in the <code>NAME</code> parameter. Try to make the two parameters work together so that a <code>pkginfo -l</code> will provide a fairly comprehensive textual description of the package.</p>
VENDOR	<p>Used to identify the vendor that holds the software copyright (maximum length of 256 ASCII characters).</p>
HOTLINE	<p>Phone number and/or mailing address where further information may be received or bugs may be reported (maximum length of 256 ASCII characters).</p>
EMAIL	<p>An electronic address where further information is available or bugs may be reported (maximum length of 256 ASCII characters).</p>
VSTOCK	<p>The vendor stock number, if any, that identifies this product (maximum length of 256 ASCII characters).</p>
CLASSES	<p>A space-separated list of classes defined for a package. The order of the list determines the order in which the classes are installed. Classes listed first will be installed first (on a media by media basis). This parameter may be modified by the request script.</p>
ISTATES	<p>A list of allowable run states for package installation (for example, "S s 1" allows run states of S, s or 1). The Solaris operating environment supports the run levels s, S, 0, 1, 2, 3, 5, and 6.</p>

	Applicable run levels for this parameter are <i>s</i> , <i>S</i> , 1, 2, and 3. See <code>init(1M)</code> for details.
RSTATES	A list of allowable run states for package removal (for example, " <i>s s 1</i> " allows run states of <i>S</i> , <i>s</i> or 1). The Solaris operating environment supports the run levels <i>s</i> , <i>S</i> , 0, 1, 2, 3, 5, and 6. Applicable run levels for this parameter are <i>s</i> , <i>S</i> , 1, 2, and 3 See <code>init(1M)</code> for details.
BASEDIR	The pathname to a default directory where "relocatable" files may be installed. If blank, the package is not relocatable and any files that have relative pathnames will not be installed. An administrator can override the default directory.
ULIMIT	If set, this parameter is passed as an argument to the <code>ulimit(1)</code> command (see <code>limit(1)</code>), which establishes the maximum size of a file during installation.
ORDER	A list of classes defining the order in which they should be put on the medium. Used by <code>pkgmk(1)</code> in creating the package. Classes not defined in this field are placed on the medium using the standard ordering procedures.
MAXINST	The maximum number of package instances that should be allowed on a machine at the same time. By default, only one instance of a package is allowed. This parameter must be set in order to have multiple instances of a package. In order to support multiple instances of packages (for example, packages that differ in their ARCH or VERSION parameter value), the value of this parameter must be high enough to allow for all instances of a given package, including multiple versions coexisting on a software server.
PSTAMP	Production stamp used to mark the <code>pkgmap(4)</code> file on the output volumes. Provides a means for distinguishing between production copies of a version if more than one is in use at a time. If PSTAMP is not defined, the default is used. The default consists of the UNIX system machine name followed by the string "YYYYMMDDHHMMSS" (year, month, date, hour, minutes, seconds).
INTONLY	Indicates that the package should only be installed interactively when set to any non-null value.
SUNW_PRODNAME	Solaris-only parameter indicating the name of the product this package is a part of or comprises (maximum length of 256 ASCII characters). A few examples of currently used SUNW_PRODNAME values are: "SunOS", "OpenWindows", and "Common Desktop Environment".

pkginfo(4)

SUNW_PRODVERS	<p>Solaris-only parameter indicating the version or release of the product described in SUNW_PRODNAME (maximum length of 256 ASCII characters). For example, where SUNW_PRODNAME="SunOS", and the Solaris 2.x Beta release, this string could be "5.x BETA", while for the Solaris 2.x FCS release, the string would be "5.x". For Solaris 8, the string is "5.8". If the SUNW_PRODNAME parameter is NULL, so should be the SUNW_PRODVERS parameter.</p>
SUNW_PKGVERS	<p>Solaris-only parameter indicating of version of the Solaris operating environment package interface.</p> <p>SUNW_PKGVERS="<sunw_package_version>"</p> <p>where <unw_package_version> has the form x.y[.z] and x, y, and z are integers. For packages built for this release and previous releases, use SUNW_PKGVERS="1.0".</p>
SUNW_PKGTYPE	<p>Solaris-only parameter for Sun internal use only. Required for packages part of the The Solaris operating environment releases which install into the /, /usr, /usr/kvm, and /usr/openwin file systems. The The Solaris operating environment installation software must know which packages are part of which file system to properly install a server/client configuration. The currently allowable values for this parameter are root, usr, kvm, and ow. If no SUNW_PKGTYPE parameter is present, the package is assumed to be of BASEDIR= /opt. SUNW_PKGTYPE is optional only for packages which install into the /opt name space as is the case for the majority of Solaris add-on software. See the SUNW_PKGTYPE parameter in packagetoc(4) for further information.</p>
SUNW_ISA	<p>Solaris-only optional parameter that indicates a software package contains 64-bit objects if it is set to sparcv9. If this parameter is not set, the default ISA (instruction set architecture) is set to the value of the ARCH parameter.</p>
SUNW_LOC	<p>Solaris-only optional parameter used to indicate a software package containing localization files for a given product or application. The parameter value is a comma-separated list of locales supported by a package. It is only used for packages containing localization files, typically the message catalogues. The allowable values for this string field are those found in the table of Standard Locale Names located in the <i>International Language Environments Guide</i>.</p> <p>SUNW_LOC="<locale_name>, <locale_name>, . . . , <locale_name>"</p> <p>where</p> <p><locale_name> ::= <language> [_<territory>] [.<codeset>] <language> ::= the set of names from ISO 639</p>

<territory> ::= the set of territories specified in ISO 3166
 <codeset> ::= is a string corresponding to the coded character set

Since a value of C specifies the traditional UNIX system behavior (American English, en_US), packages belonging to the C locale are viewed as non-localized packages, and thus must not have SUNW_LOC and SUNW_PKGLIST included in their pkginfo file. See also the SUNW_LOC parameter in `packagetoc(4)` and `setlocale(3C)` for more information. This keyword is not recognized by the add-on software utility Software Manager.

SUNW_PKGLIST Solaris-only optional parameter used to associate a localization package to the package(s) from which it is derived. It is required whenever the SUNW_LOC parameter is defined. This parameter value is an comma-separated list of package abbreviations of the form:

```
SUNW_PKGLIST="pkg1[:version] , pkg2[:version] , . . ."
```

where *version* (if specified) should match the version string in the base package specified (see `VERSION` parameter in this manual page). When in use, `SUNW_PKGLIST` helps determine the order of package installation. The packages listed in the parameter will be installed before the localization package in question is installed. When left blank, `SUNW_PKGLIST=""`, the package is assumed to be required for the locale to function correctly. See the `SUNW_PKGLIST` parameter in `packagetoc(4)` for more information. This keyword is not recognized by the add-on software utility Software Manager.

EXAMPLES **EXAMPLE 1** A sample pkginfo file

Application Packaging Developer's Guide

International Language Environments Guide

NOTES Developers may define their own installation parameters by adding a definition to this file. A developer-defined parameter must begin with a capital letter.

Trailing white space after any parameter value is ignored. For example, `VENDOR="Sun Microsystems, Inc."` is the same as `VENDOR="Sun Microsystems, Inc. "`.

NAME	pkgmap – package contents description file
DESCRIPTION	<p data-bbox="454 357 1424 430">pkgmap is an ASCII file that provides a complete listing of the package contents. It is automatically generated by <code>pkgmk(1)</code> using the information in the <code>prototype(4)</code> file.</p> <p data-bbox="454 441 1424 577">Each entry in <code>pkgmap</code> describes a single “deliverable object file.” A deliverable object file includes shell scripts, executable objects, data files, directories, and so forth. The entry consists of several fields of information, each field separated by a space. The fields are described below and must appear in the order shown.</p> <p data-bbox="454 588 1424 745"><i>part</i> An optional field designating the part number in which the object resides. A part is a collection of files and is the atomic unit by which a package is processed. A developer can choose the criteria for grouping files into a part (for example, based on class). If no value is defined in this field, part 1 is assumed.</p> <p data-bbox="454 756 1424 1354"><i>ftype</i> A one-character field that indicates the file type. Valid values are:</p> <ul style="list-style-type: none"> <li data-bbox="673 798 1424 829">b block special device <li data-bbox="673 840 1424 871">c character special device <li data-bbox="673 882 1424 913">d directory <li data-bbox="673 924 1424 997">e a file to be edited upon installation or removal (may be shared by several packages) <li data-bbox="673 1008 1424 1039">f a standard executable or data file <li data-bbox="673 1050 1424 1081">i installation script or information file <li data-bbox="673 1092 1424 1123">l linked file <li data-bbox="673 1134 1424 1165">p named pipe <li data-bbox="673 1176 1424 1207">s symbolic link <li data-bbox="673 1218 1424 1291">v volatile file (one whose contents are expected to change, like a log file) <li data-bbox="673 1302 1424 1354">x an exclusive directory accessible only by this package <p data-bbox="454 1365 1424 1459"><i>class</i> The installation class to which the file belongs. This name must contain only alphanumeric characters and be no longer than 12 characters. It is not specified if the <i>ftype</i> is <code>i</code> (information file).</p> <p data-bbox="454 1470 1424 1606"><i>pathname</i> <i>pathname</i> may contain variables of the form <code>\$variable</code> that support install-time configuration of the file. <i>variable</i> may be embedded in the <i>pathname</i> structure. (See <code>prototype(4)</code> for definitions of variable specifications.)</p> <p data-bbox="673 1617 1424 1686">Do not use the following reserved words in <i>pathname</i>, since they are applied by <code>pkgadd(1M)</code> using a different mechanism:</p>

pkgmap(4)

	PKG_INSTALL_ROOT BASEDIR CLIENT_BASEDIR
<i>major</i>	The major device number. The field is only specified for block or character special devices.
<i>minor</i>	The minor device number. The field is only specified for block or character special devices.
<i>mode</i>	<p>The octal mode of the file (for example, 0664). A question mark (?) indicates that the mode will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked files, packaging information files, or non-installable files.</p> <p>The mode can contain a variable specification. (See <code>prototype(4)</code> for definitions of variable specifications.)</p>
<i>owner</i>	<p>The owner of the file (for example, <code>bin</code> or <code>root</code>). The field is limited to 14 characters in length. A question mark (?) indicates that the owner will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked files or non-installable files. It is used optionally with a package information file. If used, it indicates with what owner an installation script will be executed.</p> <p>The owner can contain a variable specification. (See <code>prototype(4)</code> for definitions of variable specifications.)</p>
<i>group</i>	<p>The group to which the file belongs (for example, "bin" or "sys"). The field is limited to 14 characters in length. A question mark (?) indicates that the group will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked files or non-installable files. It is used optionally with a package information file. If used, it indicates with what group an installation script will be executed.</p> <p>The group can contain a variable specification. (See <code>prototype(4)</code> for definitions of variable specifications.)</p>
<i>size</i>	The actual size of the file in bytes. This field is not specified for named pipes, special devices, directories or linked files.
<i>cksum</i>	The checksum of the file contents. This field is not specified for named pipes, special devices, directories, or linked files.
<i>modtime</i>	The time of last modification, as reported by the <code>stat(2)</code> function call. This field is not specified for named pipes, special devices, directories, or linked files.

Each pkgmap file must have one line that provides information about the number of parts, maximum size of parts that make up the package, and, optionally, the size of the package after compression (where size is given in 512-byte blocks). This line is in the following format:

```
: number_of_parts maximum_part_size compressed_pkg_size
```

Lines that begin with “#” are comment lines and are ignored.

When files are saved during installation before they are overwritten, they are normally just copied to a temporary pathname. However, for files whose mode includes execute permission (but which are not editable), the existing version is linked to a temporary pathname and the original file is removed. This allows processes which are executing during installation to be overwritten.

Application Packaging Developer's Guide

NOTES

The pkgmap file may contain only one entry per unique pathname.

platform(4)

NAME	platform – directory of files specifying supported platforms
SYNOPSIS	<code>.platform</code>
DESCRIPTION	<p>The Solaris 2.5 release includes the <code>.platform</code> directory, a new directory on the Solaris CD image. This directory contains files (created by SunSoft and Solaris OEMs) that define platform support. These files are generically referred to as <i>platform definition files</i>. They provide a means to map different platform types into a platform group.</p> <p>Platform definition files in the <code>.platform</code> directory are used by the installation software to ensure that software appropriate for the architecture of the system will be installed.</p> <p>SunSoft provides a platform definition file named <code>.platform/Solaris</code>. This file is the only one that can define platform groups to which other platform definition files can refer. For example, an OEM platform definition file can refer to any platform group specified in the Solaris platform definition file.</p> <p>Other platform definition files are delivered by OEMs. To avoid name conflicts, OEMs will name their platform definition file with an OEM-unique string. OEM's should use whatever string they use to make their package names unique. This unique string is often the OEM's stock symbol.</p> <p>Comments are allowed in a platform definition file. A "#" begins a comment and can be placed anywhere on a line.</p> <p>Platform definition files are composed of keyword-value pairs, and there are two kinds of stanzas in the file: platform group definitions and platform identifications.</p> <ul style="list-style-type: none">■ Platform group definitions: The keywords in a platform group definition stanza are: <code>PLATFORM_GROUP</code> The <code>PLATFORM_GROUP</code> keyword <i>must</i> be the first keyword in the platform group definition stanza. The value assigned to this keyword is the name of the platform group, for example: <code>PLATFORM_GROUP=sun4c</code> The <code>PLATFORM_GROUP</code> name is an arbitrary name assigned to a group of platforms. However, <code>PLATFORM_GROUP</code> typically equals the output of the <code>uname -m</code> command. <code>PLATFORM_GROUP</code> value cannot have white space and is limited to 256 ASCII characters.<code>INST_ARCH</code> The instruction set architecture of all platforms in the platform group, for example: <code>INST_ARCH=sparc</code> The <code>INST_ARCH</code> keyword value must be the value returned by the <code>uname -p</code> command on all platforms in the platform group.

- Platform identifications:

The keywords in a platform identification stanza are:

PLATFORM_NAME	<p>The PLATFORM_NAME keyword <i>must</i> be the first keyword in the platform identification stanza. The PLATFORM_NAME is the name assigned to the platform, for example:</p> <pre>PLATFORM_NAME=SUNW,SPARCstation-5</pre> <p>Typically, this name is the same as the value returned by the <code>uname -i</code> command on the machine, but it need not be the same.</p> <p>The PLATFORM_NAME value cannot have white space and is limited to 256 ASCII characters. If it contains parentheses, it must contain only balanced parentheses. For example, the string "foo(bar)foo" is a valid value for this keyword, but "foo(bar" is not.</p> <p>The other keywords in the platform identification stanza can be in any order, as long as the PLATFORM_NAME keyword is first.</p>
PLATFORM_ID	<p>The value returned by the <code>uname -i</code> command on the machine, for example:</p> <pre>PLATFORM_ID=SUNW,SPARCstation-5</pre>
MACHINE_TYPE	<p>The value returned by the <code>uname -m</code> command on the machine, for example:</p> <pre>MACHINE_TYPE=sun4c</pre>
IN_PLATFORM_GROUP	<p>The platform group of which the platform is a member, for example:</p> <pre>IN_PLATFORM_GROUP=sun4c</pre> <p>The platform group name must be specified in the same file as the platform identification stanza or in the platform definition file with the name <code>.platform/Solaris</code>.</p> <p>The IN_PLATFORM_GROUP keyword is optional. A platform doesn't have to belong to a platform group. If a platform isn't explicitly assigned to a platform group, it essentially forms its own platform group, where the platform group name is the PLATFORM_NAME value. The</p>

platform(4)

	<p>IN_PLATFORM_GROUP value typically equals the output of the <code>uname -m</code> command.</p> <p>IN_PLATFORM_GROUP value cannot have white space and is limited to 256 ASCII characters.</p>
<code>INST_ARCH</code>	<p>The instruction set architecture of the platform, for example:</p> <pre>INST_ARCH=sparc</pre> <p>This field is only required if the platform does not belong to a platform group. The <code>INST_ARCH</code> keyword value must be the value returned by the <code>uname -p</code> command on all platforms in the platform group.</p>
COMPATIBILITY	<p>The installation program will remain compatible with the old Solaris CD format. If a Solaris CD image does not contain any platform definition files, the installation and upgrade programs will select the packages to be installed based on machine type (i.e., the value returned by the <code>uname -m</code> command).</p>
EXAMPLES	<p>EXAMPLE 1 The following example shows platform group definitions from the <code>.platform/Solaris</code> platform definition file.</p> <pre># PLATFORM_GROUP=sun4c INST_ARCH=sparc # PLATFORM_GROUP=sun4d INST_ARCH=sparc # PLATFORM_GROUP=sun4m INST_ARCH=sparc # PLATFORM_GROUP=sun4u INST_ARCH=sparc</pre> <p>EXAMPLE 2 The following example shows platform identification stanzas, which define systems that belong in a platform group, from the <code>.platform/Solaris</code> platform definition file.</p> <pre># PLATFORM_NAME=SUNW, Sun_4_20 PLATFORM_ID=SUNW, Sun_4_20 IN_PLATFORM_GROUP=sun4c PLATFORM_NAME=SUNW, Sun_4_25 PLATFORM_ID=SUNW, Sun_4_25 IN_PLATFORM_GROUP=sun4c # PLATFORM_NAME=SUNW, SPARCstation-5 PLATFORM_ID=SUNW, SPARCstation-5 IN_PLATFORM_GROUP=sun4m # PLATFORM_NAME=SUNW, SPARCstation-10</pre>

EXAMPLE 2 The following example shows platform identification stanzas, which define systems that belong in a platform group, from the .platform/Solaris platform definition file. (Continued)

```
PLATFORM_ID=SUNW,SPARCstation-10
IN_PLATFORM_GROUP=sun4m
```

FILES The .platform directory must reside as / *cd_image*/Solaris_*vers*/.platform, where

cd_image Is the path to the mounted Solaris CD (/cdrom/cdrom0/s0 by default) or the path to a copy of the Solaris CD on a disk.

Solaris_*vers* Is the version of Solaris: e.g., Solaris_2.5.

NOTES Typically, a platform identification stanza contains either a PLATFORM_ID or a MACHINE_TYPE stanza, but *not* both.

If both are specified, both must match for a platform to be identified as this platform type. Each platform identification stanza must contain either a PLATFORM_ID value or a MACHINE_TYPE value. If a platform matches two different platform identification stanzas—one which matched on the value of PLATFORM_ID and one which matched on the value of MACHINE_TYPE, the one that matched on PLATFORM_ID will take precedence.

The .platform directory is part of the Solaris CD image, whether that be the Solaris CD or a copy of the Solaris CD on a system's hard disk.

plot(4B)

NAME	plot – graphics interface
DESCRIPTION	<p>Files of this format are interpreted for various devices by commands described in <code>plot(1B)</code>. A graphics file is a stream of plotting instructions. Each instruction consists of an ASCII letter usually followed by bytes of binary information. The instructions are executed in order. A point is designated by four bytes representing the x and y values; each value is a signed integer. The last designated point in an <code>l</code>, <code>m</code>, <code>n</code>, or <code>p</code> instruction becomes the “current point” for the next instruction.</p> <p><code>m</code> Move: the next four bytes give a new current point.</p> <p><code>n</code> Cont: draw a line from the current point to the point given by the next four bytes. See <code>plot(1B)</code>.</p> <p><code>p</code> Point: plot the point given by the next four bytes.</p> <p><code>l</code> Line: draw a line from the point given by the next four bytes to the point given by the following four bytes.</p> <p><code>t</code> Label: place the following ASCII string so that its first character falls on the current point. The string is terminated by a NEWLINE.</p> <p><code>a</code> Arc: the first four bytes give the center, the next four give the starting point, and the last four give the end point of a circular arc. The least significant coordinate of the end point is used only to determine the quadrant. The arc is drawn counter-clockwise.</p> <p><code>c</code> Circle: the first four bytes give the center of the circle, the next two the radius.</p> <p><code>e</code> Erase: start another frame of output.</p> <p><code>f</code> Linemod: take the following string, up to a NEWLINE, as the style for drawing further lines. The styles are “dotted,” “solid,” “longdashed,” “shortdashed,” and “dotdashed.” Effective only in <code>plot 4014</code> and <code>plot ver</code>.</p> <p><code>s</code> Space: the next four bytes give the lower left corner of the plotting area; the following four give the upper right corner. The plot will be magnified or reduced to fit the device as closely as possible.</p> <p>Space settings that exactly fill the plotting area with unity scaling appear below for devices supported by the filters of <code>plot(1B)</code>. The upper limit is just outside the plotting area.</p> <p>In every case the plotting area is taken to be square; points outside may be displayable on devices whose face is not square.</p> <pre>4014 space(0, 0, 3120, 3120); ver space(0, 0, 2048, 2048); 300, 300s space(0, 0, 4096, 4096); 450 space(0, 0, 4096, 4096);</pre>

plot(4B)

SEE ALSO graph(1), plot(1B)

policy.conf(4)

NAME	policy.conf – configuration file for security policy					
SYNOPSIS	/etc/security/policy.conf					
DESCRIPTION	<p>The <code>policy.conf</code> file provides the security policy configuration for user-level attributes. Each entry consists of a key/value pair in the form:</p> <pre>key=value</pre> <p>The following keys are defined:</p> <table><tr><td>AUTHS_GRANTED</td><td>Specifies the default set of authorizations granted to all users. This entry is interpreted by <code>chkauthattr(3SECDB)</code>. The value is one or more comma-separated authorizations defined in <code>auth_attr(4)</code>.</td></tr><tr><td>PROFS_GRANTED</td><td>Specifies the default set of profiles granted to all users. This entry is interpreted by <code>chkauthattr(3SECDB)</code> and <code>getexecuser(3SECDB)</code>. NAME	power.conf – Power Management configuration information file
SYNOPSIS	<code>/etc/power.conf</code>
DESCRIPTION	<p>The <code>power.conf</code> file is used by the Power Management configuration program <code>pmconfig(1M)</code>, to initialize the settings for Power Management. If you make changes to this file, you must run <code>pmconfig(1M)</code> manually for the changes to take effect.</p> <p>The <code>dtpower(1M)</code> GUI allows the configuration of a subset of parameters allowed by this file. For ease-of-use, it is recommended that you use <code>dtpower(1M)</code> to configure the parameters.</p> <p>Power Management addresses two specific management scenarios: management of individual devices and management of the whole system. An individual device is power managed if a device supports multiple power levels and if the device driver uses Power Management interfaces provided by the kernel to save device power when the device is idle. If the driver uses the original Power Management interfaces, the device is controlled by the entries described in the DEVICE POWER MANAGEMENT section of this manual page. If the device driver uses new automatic device Power Management interfaces, the device is controlled by the entries described in the AUTOMATIC DEVICE POWER MANAGEMENT section of this manual page.</p> <p>To determine if the device driver supports original Power Management interfaces, contact the device vendor. To find out if the device driver supports the new automatic device Power Management interfaces, look for “pm-components” property (<code>pm-components(9P)</code>) under the device name from the output of <code>prtconf -v</code> command (<code>prtconf(1M)</code>.)</p> <p>The original Power Management interfaces and the corresponding device Power Management entries in <code>power.conf</code> file that were supported in Solaris 7 and earlier releases are now obsolete. Support for them will be removed in a future release.</p> <p>All entries in the <code>power.conf</code> file are processed in the order displayed in the file.</p> <p>Device Power Management</p> <p>Device Power Management entries are now obsolete and support for them will be removed in a future release. If a device supports original Power Management interfaces, it needs to be explicitly configured for Power Management using an entry of the form shown below. A device will not be power managed if there is no entry for the device. Be sure you fully understand the Power Management framework before you attempt to modify device Power Management entries.</p> <p>Device Power Management entries consist of line-by-line listings of the devices to be configured. Each line is of the form:</p> <pre><i>device_name threshold . . . dependent_upon . . .</i></pre> <p>The fields must be in the order shown above. Each line must contain a <i>device_name</i> field and a <i>threshold</i> field; it may also contain a <i>dependent_upon</i> field. Fields and sub-fields are separated by white space (tabs or spaces). A line may be more than 80</p>

power.conf(4)

characters. If a newline character is preceded by a backslash (\) it will be treated as white space. Comment lines must begin with a hash character (#).

The *device_name* field specifies the device to be configured. *device_name* is either a pathname specifying the device special file or a relative pathname containing the name of the device special file. (For the latter format, you can avoid using the full pathname by omitting the pathname component that specifies the parent devices. This includes the leading '/'.) Using the relative pathname format, the first device found with a full pathname containing *device_name* as its tail is matched. In either case, the leading */devices* component of the pathname does not need to be specified.

The *threshold* field is used to configure the power manageable components of a device. These components represent entities within a device that may be power-managed separately. This field may contain as many integer values as the device has components. Each *threshold* time specifies the idle time in seconds before the respective component may be powered down. If there are fewer component *threshold* times than device components, the remaining components are not power managed. Use a value of -1 to explicitly disable power-down for a component. At least one component *threshold* must be specified per device (in the file).

The *dependent_upon* field contains a list of devices that must be idle and powered-down before the dependent device in *device_name* field can be powered down. A device must previously have been configured before it can be used in *dependent_upon* list. This field should only list logical dependents for this device. A logical dependent is a device that is not physically connected to the power managed device (for example, the display and the keyboard). Physical dependents are automatically considered and do not need to be included.

A device Power Management entry is only effective if there is no user process controlling the device directly. For example, X Window systems directly control framebuffers and entries in this file are effective only when X Windows are not running.

Automatic Device Power Management

Devices whose drivers use the new automatic device Power Management interfaces (as evident by existence of *pm-component s(9P)* property) are automatically power managed if enabled by the *autopm* entry described below.

When a component has been idle at a given power level for its *threshold* time, the power level of the component will be reduced to the next lower power level of that component (if any). For devices which implement multiple components, each component is power-managed independently.

Default thresholds for components of automatically power managed devices are computed by the Power Management framework based on the system idleness *threshold*. By default, all components of the device are powered off if they have all been idle for the system's idleness *threshold*. The default system idleness *threshold* is

determined by the applicable United States Environmental Protection Agency's (EPA) *Energy Star Memorandum of Understanding*. See the NOTES section of this manual page for more information.

To set the system idleness *threshold*, use one of the following entries:

```
system-threshold    threshold
system-threshold    always-on
```

where *threshold* is the value of the system idleness threshold in hours, minutes or seconds as indicated by a trailing h, m or s (defaulting to seconds if only a number is given). If *always-on* is specified, then by default, all devices will be left at full power.

To override the default device component thresholds assigned by the Power Management framework, a *device-thresholds* entry may be used. A *device-thresholds* entry sets thresholds for a specific automatically power-managed device or disables automatic Power Management for the specific device.

A *device-thresholds* entry has the form:

```
device-thresholds  phys_path (threshold ...) ...
```

or

```
device-thresholds  phys_path threshold
```

or

```
device-thresholds  phys_path always-on
```

where *phys_path* specifies the physical path (`libdevinfo(3)`) of a specific device. For example, `/pci@3,600000/scsi@4/ssd@w210000203700c3ee,0` specifies the physical path of a disk. A symbolic link into the `/devices` tree (for example `/dev/dsk/c1t1d0s0`) is also accepted. The thresholds apply (or keeping the device always on applies) to the specific device only.

In the first form above, each *threshold* value represents the number of hours, minutes or seconds (depending on a trailing h, m or s with a default to seconds) to spend idle at the corresponding power level before power will be reduced to the next lower level of that component. Parentheses are used to group thresholds per component, with the first (leftmost) group being applied to component 0, the next to component 1, etc. Within a group, the last (rightmost) number represents the time to be idle in the highest power level of the component before going to the next-to-highest level, while the first (leftmost) number represents the time to be idle in the next-to-lowest power level before going to the lowest power level.

If the number of groups does not match the number of components exported by the device (by means of `pm-components(9P)` property), or the number of thresholds in a

power.conf(4)

group is not one less than the number of power levels the corresponding component supports, then an error message will be printed and the entry will be ignored.

For example, assume a device called *xfb* exports the components *Frame Buffer* and *Monitor*. Component *Frame Buffer* has two power levels: *Off* and *On*. Component *Monitor* has four power levels: *Off*, *Suspend*, *Standby*, and *On*.

The following `device-thresholds` entry:

```
device-thresholds /pci@f0000/xfb@0 (0) (3m 5m 15m)
```

would set the *threshold* time for the *Monitor* component of the specific *xfb* card to go from *On* to *Standby* in 15 minutes, the *threshold* for *Monitor* to go from *Standby* to *Suspend* in 5 minutes, and the *threshold* for *Monitor* to go from *Suspend* to *Off* in 3 minutes. The threshold for *Frame Buffer* to go from *On* to *Off* will be 0 seconds.

In the second form above, where a single *threshold* value is specified without parentheses, the *threshold* value represents a maximum overall time within which the entire device should be powered down if it is idle. Because the system does not know about any internal dependencies there may be among a device's components, the device may actually be powered down sooner than the specified *threshold*, but will not take longer than the specified *threshold*, provided that all device components are idle.

In the third form above, all components of the device are left at full power.

Device Power Management entries are only effective if there is no user process controlling the device directly. For example, X Window systems directly control frame buffers and the entries in this file are effective only when X Windows are not running.

Dependencies among devices may also be defined. A device depends upon another if none of its components may have their power levels reduced unless all components of the other device are powered off. A dependency may be indicated by an entry of the form:

```
device-dependency dependent_phys_path phys_path [ phys_path ... ]
```

where *dependent_phys_path* is the path name (as above) of the device that is kept up by the others, and the *phys_path* entries specify the devices that keep it up. A symbolic link into the `/devices` tree (such as `/dev/fb`) is also accepted. This entry is needed only for logical dependents for the device. A logical dependent is a device that is not physically connected to the power managed device (for example, the display and the keyboard). Physical dependents are automatically considered and need not be included.

In addition to listing dependents by physical path, an arbitrary group of devices can be made dependent upon another device by specifying a property dependency using the following syntax:

```
device-dependency-property property phys_path [ phys_path ... ]
```

where each device that exports the property *property* will be kept up by the devices named by *phys_path*(s). A symbolic link into the */devices* tree (such as */dev/fb*) is accepted as well as a pathname for *phys_path*.

For example, the following entry:

```
# This entry keeps removable media from being powered down unless the
# console framebuffer and monitor are powered down
# (See removable-media(9P))
#
device-dependency-property removable-media /dev/fb
```

ensures that every device that exports the boolean property named *removable-media* will be kept up when the console framebuffer is up. (See *removable-media*(9P).)

An *autopm* entry may be used to enable or disable automatic device Power Management on a system-wide basis. The format of the *autopm* entry is:

```
autopmbehavior
```

Acceptable behavior values and their meanings are:

default	The behavior of the system will depend upon its model. Desktop models that fall under the United States Environmental Protection Agency's <i>Energy Star Memorandum of Understanding #3</i> will have automatic device Power Management enabled, and all others will not. See the NOTES section of this manual page for more information.
enable	Automatic device Power Management will be started when this entry is encountered.
disable	Automatic device Power Management will be stopped when this entry is encountered.

System Power Management

The system Power Management entries control power management of the entire system using the suspend-resume feature. When the system is suspended, the complete current state is saved on the disk before power is removed. On reboot, the system automatically starts a resume operation and the system is restored to the state it was in prior to suspend.

The system can be configured to do an automatic shutdown (*autoshtutdown*) using the suspend-resume feature by an entry of the following form:

```
autoshtutdown idle_time start_time finish_time behavior
```

idle_time specifies the time in minutes that system must have been idle before it will be automatically shutdown. System idleness is determined by the inactivity of the system and can be configured as discussed below.

power.conf(4)

start_time and *finish_time* (each in hh:mm) specify the time period during which the system may be automatically shutdown. These times are measured from the start of the day (12:00 a.m.). If the *finish_time* is less than or equal to the *start_time*, the period span from midnight to the *finish_time* and from the *start_time* to the following midnight. To specify continuous operation, the *finish_time* may be set equal to the *start_time*.

Acceptable *behavior* values and their meanings are:

shutdown	The system will be shut down automatically when it has been idle for the number of minutes specified in the <i>idle_time</i> value and the time of day falls between the <i>start_time</i> and <i>finish_time</i> values.
noshutdown	The system is never shut down automatically.
autowakeup	If the hardware has the capability to do autowakeup, the system is shut down as if the value were shutdown and the system will be restarted automatically the next time the time of day equals <i>finish_time</i> .
default	The behavior of the system will depend upon its model. Desktop models that fall under the United States Environmental Protection Agency's <i>Energy Star Memorandum of Understanding #2</i> will have automatic shutdown enabled (as if <i>behavior</i> field were set to shutdown), and all others will not. See NOTES.
unconfigured	The system will not be shut down automatically. If the system has just been installed or upgraded, the value of this field will be changed upon the next reboot.

You can use the following format to configure the system's notion of idleness:

idleness_parameter value

Where *idleness_parameter* can be:

ttychars	If the <i>idleness_parameter</i> is <i>ttychars</i> , the <i>value</i> field will be interpreted as the maximum number of tty characters that can pass through the <i>ldterm</i> module while still allowing the system to be considered idle. This value defaults to 0 if no entry is provided.
loadaverage	If the <i>idleness_parameter</i> is <i>loadaverage</i> , the (floating point) <i>value</i> field will be interpreted as the maximum load average that can be seen while still allowing the system to be considered idle. This value defaults to 0.04 if no entry is provided.
diskreads	If the <i>idleness_parameter</i> is <i>diskreads</i> , the <i>value</i> field will be interpreted as the maximum number of disk reads that can be performed by the system while still allowing the system to be considered idle. This value defaults to 0 if no entry is provided.

nfsreqs	If the <i>idleness_parameter</i> is <i>nfsreqs</i> , the <i>value</i> field will be interpreted as the maximum number of NFS requests that can be sent or received by the system while still allowing the system to be considered idle. Null requests, access requests, and getattr requests are excluded from this count. This value defaults to 0 if no entry is provided.
idlecheck	If the <i>idleness_parameter</i> is <i>idlecheck</i> , the <i>value</i> must be pathname of a program to be executed to determine if the system is idle. If <i>autoshtutdown</i> is enabled and the console keyboard, mouse, tty, CPU (as indicated by load average), network (as measured by NFS requests) and disk (as measured by read activity) have been idle for the amount of time specified in the <i>autoshtutdown</i> entry specified above, and the time of day falls between the start and finish times, then this program will be executed to check for other idleness criteria. The <i>value</i> of the idle time specified in the above <i>autoshtutdown</i> entry will be passed to the program in the environment variable <i>PM_IDLETIME</i> . The process must terminate with an exit code that represents the number of minutes that the process considers the system to have been idle.

There is no default *idlecheck* entry.

When the system is suspended, the current system state is saved on the disk in a statefile. An entry of following form can be used to change the location of statefile:

```
statefile pathname
```

where *pathname* identifies a block special file, for example, */dev/dsk/c1t0d0s2*, or is the absolute pathname of a local ufs file. If the pathname specifies a block special file, it can be a symbolic link as long as it does not have a file system mounted on it. If pathname specifies a local ufs file, it cannot be a symbolic link. If the file does not exist, it will be created during the suspend operation. All the directory components of the path must already exist.

The actual size of statefile depends on a variety of factors, including the size of system memory, the number of loadable drivers/modules in use, the number and type of processes running, and the amount of user memory that has been locked down. It is recommended that statefile be placed on a file system with at least 10 Mbytes of free space. In case there is no statefile entry at boot time, an appropriate new entry is automatically created by the system.

ATTRIBUTES

Writing Device Drivers

Solaris Common Desktop Environment: User's Guide

NOTES SPARC desktop models first shipped after October 1, 1995 and before July 1, 1999 comply with the United States Environmental Protection Agency's *Energy Star Memorandum of Understanding #2* guidelines and have `autoshtdownenabled` by default after 30 minutes of system idleness. This is achieved by `default` keyword of `autoshtdown` entry behave as `shutdown` for these machines. The user is prompted to confirm this default behavior at system installation reboot, or during the first reboot after the system is unconfigured by `sys-unconfig(1M)`.

SPARC desktop models first shipped after July 1, 1999 comply with the United States Environmental Protection Agency's *Energy Star Memorandum of Understanding #3* guidelines and have `autoshtdowndisabled` by default, with `autopm` enabled after 30 minutes of idleness. This is achieved by interpreting default keyword of `autopm` entry behavior as `enabled` for these machines. User is not prompted to confirm this default behavior.

To determine the version of the EPA's *Energy Star Memorandum* applicable to your machine, use:

```
prtconf -pv | grep -i energystar
```

Absence of a property indicates no Energy Star guidelines are applicable to your machine.

System Power Management (`suspend-resume`) is currently supported only on a limited set of hardware platforms. Please see the book *Solaris Common Desktop Environment: User's Guide* for a complete list of platforms that support system Power Management. See `uname(2)` to programatically determine if the machine supports `suspend-resume`.

NAME	printers – user-configurable printer alias database
SYNOPSIS	<code>\$HOME/.printers</code>
DESCRIPTION	<p>The <code>\$HOME/.printers</code> file is a simplified version of the system <code>/etc/printers.conf</code> file (see <code>printers.conf(4)</code>). Users create the <code>\$HOME/.printers</code> file in their home directory. This optional file is customizable by the user.</p> <p>The <code>\$HOME/.printers</code> file performs the following functions:</p> <ol style="list-style-type: none"> 1. Sets personal aliases for all print commands. 2. Sets the interest list for the <code>lpget</code>, <code>lpstat</code>, and <code>cancel</code> commands. See <code>lpget(1M)</code>, <code>lpstat(1)</code> and <code>cancel(1)</code>. 3. Sets the default printer for the <code>lp</code>, <code>lpr</code>, <code>lpq</code>, and <code>lprm</code> commands. See <code>lp(1)</code>, <code>lpr(1B)</code>, <code>lpq(1B)</code>, and <code>lprm(1B)</code>. <p>Entries Use a line or full screen editor to create or modify the <code>\$HOME/.printers</code> file.</p> <p>Each entry in <code>\$HOME/.printers</code> describes one destination. Entries are one line consisting of two fields separated by either BLANKs or TABs and terminated by a NEWLINE. Format for an entry in <code>\$HOME/.printers</code> varies according to the purpose of the entry.</p> <p>Empty lines can be included for readability. Entries may continue on to multiple lines by adding a backslash (<code>\</code>) as the last character in the line. The <code>\$HOME/.printers</code> file can include comments. Comments have a pound sign (<code>#</code>) as the first character in the line, and are terminated by a NEWLINE.</p> <p>Setting Personal Aliases</p> <p>Specify the alias or aliases in the first field. Separate multiple aliases by a pipe sign (<code> </code>). Specify the destination in the second field. A destination names a printer or class of printers (see <code>lpadmin(1M)</code>). Specify the destination using atomic, POSIX-style (<code>server:destination</code>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p>Setting the Interest List for <code>lpget</code>, <code>lpstat</code> and <code>cancel</code></p> <p>Specify <code>_all</code> in the first field. Specify the list of destinations for the interest list in the second field. Separate each destinations by a comma (<code>,</code>). Specify destinations using atomic, POSIX-style (<code>server:destination</code>), or FNS names (<code>.../service/printer/...</code>). See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names. This list of destinations may refer to an alias defined in <code>\$HOME/.printers</code>.</p> <p>Setting the Default Destination</p>

printers(4)

Locating Destination Information

Specify `_default` in the first field. Specify the default destination in the second field. Specify the default destination using atomic, POSIX-style (*server:destination*), or FNS names (*.../service/printer/...*). See `printers.conf(4)` for information regarding the naming conventions for atomic and FNS names. The default destination may refer to an alias defined in `$HOME/.printers`.

The print client commands locate destination information based on the “printers” database entry in the `/etc/nsswitch.conf` file. See `nsswitch.conf(4)`.

Locating the Personal Default Destination

The default destination is located differently depending on the command.

The `lp` command locates the default destination in the following order:

1. `lp` command's `-d destination` option.
2. `LPDEST` environment variable.
3. `PRINTER` environment variable.
4. `_default` destination in `$HOME/.printers`.
5. `_default` destination in `/etc/printers.conf`.
6. `_default` destination in FNS.

The `lpr`, `lpq`, and `lprm` commands locate the default destination in the following order:

1. `lpr` command's `-P destination` option.
2. `PRINTER` environment variable.
3. `LPDEST` environment variable.
4. `_default` destination in `$HOME/.printers`.
5. `_default` destination in `/etc/printers.conf`.
6. `_default` destination in FNS.

Locating the Interest List for `lpget`, `lpstat`, and `cancel`

The `lpget`, `lpstat`, and `cancel` commands locate the interest list in the following order:

1. `_all` list in `$HOME/.printers`.
2. `_all` list in `/etc/printers.conf`.
3. `_all` list in FNS.

EXAMPLES

EXAMPLE 1 Setting the interest list

The following entry sets the interest list to destinations `ps`, `secure`, and `dog` at server `west` and `finance_ps` at site `bldg2`:

```
_all      ps,secure,west:dog,site/bldg2/service/printer/finance_ps
```

EXAMPLE 1 Setting the interest list (Continued)

EXAMPLE 2 Setting aliases to a printer

The following entry sets the aliases `ps`, `lp`, and `lw` to `sparc_printer`:

```
ps|lp|lw    sparc_printer
```

EXAMPLE 3 Setting an alias as a default destination

The following entry sets the alias `pcl` to `hplj` and sets it as the default destination:

```
pcl|_default    hplj
```

EXAMPLE 4 Setting an alias to a server destination

The following entry sets the alias `secure` to destination `catalpa` at server `tabloid`:

```
secure    tabloid:catalpa
```

EXAMPLE 5 Setting an alias to a site destination

The following entry sets the alias `insecure` to destination `legal_ps` at site `bldg2`:

```
insecure    site/bldg2/service/printer/legal_ps
```

FILES	<code>\$HOME/.printers</code>	User-configurable printer database.
	<code>/etc/printers.conf</code>	System printer configuration database.

	<code>printers.org_dir</code>	NIS+ version of <code>/etc/printers.conf</code> .
	<code>fns.ctx_dir.domain</code>	FNS version of <code>/etc/printers.conf</code> .

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
Stability Level	Stable

SEE ALSO `cancel(1)`, `lp(1)`, `lpq(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `lpadmin(1M)`, `lpget(1M)`, `nsswitch.conf(4)`, `printers.conf(4)`, `attributes(5)`, `fns(5)`, `standards(5)`

System Administration Guide: Basic Administration

NOTES `$HOME/.printers` is referenced by the printing commands before further name resolution is made in `/etc/printers.conf` or the name `service`. If the alias

printers(4)

references a destination defined in `/etc/printers.conf`, it is possible that the destination is defined differently on different systems. This could cause output to be sent to an unintended destination if the user is logged in to a different system.

NAME	printers.conf – system printing configuration database
SYNOPSIS	/etc/printers.conf
NIS	printers.conf.byname
NIS+	printers.org_dir
FNS	fns.ctx_dir.domain
DESCRIPTION	<p>The <code>printers.conf</code> file is the system printing configuration database. System administrators use <code>printers.conf</code> to describe destinations for the print client commands and the print protocol adaptor. A destination names a printer or class of printers (see <code>lpadmin(1M)</code>). The LP print spooler uses private LP configuration data for represented in the <code>printers.conf</code> database.</p> <p>Entries Each entry in <code>printers.conf</code> describes one destination. Entries are one line consisting of any number of fields separated by colons (':') and terminated by a NEWLINE. The first field of each entry specifies the name of the destination and aliases to which the entry describes. Specify one or more names or aliases of the destination in this first field. Specify the destination using atomic names. POSIX-style names are not acceptable. See <code>standards(5)</code>. Separate destination names by pipe signs (' ').</p> <p>Two destination names are reserved for special use in the first entry. Use <code>_all</code> to specify the interest list for <code>lpget</code>, <code>lpstat</code>, and <code>cancel</code>. Use <code>_default</code> to specify the default destination.</p> <p>The remaining fields in an entry are <i>key=value</i> pairs. See <i>Specifying Configuration Options</i> for details regarding <i>key=value</i> pairs.</p> <p>Empty lines can be included for readability. Entries may continue on to multiple lines by adding a backslash ('\') as the last character in the line. <code>printers.conf</code> can include comments. Comments have a pound sign ('#') as the first character in the line, and are terminated by a NEWLINE. Use the <code>lpset</code> command to create or modify <code>printers.conf</code> (see <code>lpset(1M)</code>). <i>Do not make changes in printers.conf using an editor.</i></p>
Specifying Configuration Options	<p><i>key=value</i> pairs are configuration options defined by the system administrator. <i>key</i> and <i>value</i> may be of arbitrary length. Separate <i>key</i> and <i>value</i> by the equal ('=') character.</p> <p>Client/Server Configuration Options</p> <p>The following client/server configuration options (represented as <i>key=value</i> pairs) are supported:</p> <p><code>bsdaddr=server, destination[, Solaris]</code></p> <p>Sets the server and destination name. Sets if the client generates protocol extensions for use with the <code>lp</code> command (see <code>lp(1)</code>). <code>Solaris</code> specifies a Solaris print server extension. If <code>Solaris</code> is not specified, no protocol extensions are generated. <i>server</i></p>

printers.conf(4)

is the name of the host containing the queue for *destination*. *destination* is the atomic name by which the server knows the destination.

use=destination

Sets the destination to continue searching for configuration information. *destination* is an atomic or Federated Naming Service (FNS) (.../service/printer/...) name.

all=destination_list

Sets the interest list for the *lpget*, *lpstat*, and *cancel* commands. *destination_list* is a comma-separated list of destinations. Specify *destination* using atomic or FNS names (.../service/printer/...). See *lpget(1M)*, *lpstat(1)*, and *cancel(1)*.

General Server Options

The following general server configuration options (represented as *key=value* pairs) are supported:

spooling-type=spooler[,version]

Sets the type of spooler under which a destination is configured. Dynamically loads translation support for the back-end spooling system from */usr/lib/print/bsd-adaptor/bsd_spooler.so[.version]*. Specify *spooler* as *lpsched*, *cascade*, or *test*. *lpsched* is used as a default for locally attached destinations. *cascade* is used as a default for destination spooled on a remote host. Use *test* for the test module to allow the capture of print requests. If using a versioned spooler module, *version* specifies the version of the translation module.

spooling-type-path=dir_list

Sets the location of translation support for the type of spooler defined by the *spooling-type* key. Locates translation support for the type of spooler under which a destination is configured. *dir_list* is a comma-separated list of absolute pathnames to the directories used to locate translation support for the spooling system set by the *spooling-type* key.

LP Server Options

The following LP configuration options (represented as *key=value* pairs) are supported:

user-equivalence=true|false

Sets whether or not usernames are considered equivalent when cancelling a print request submitted from a different host in a networked environment. *true* means that usernames are considered equivalent, and permits users to cancel a print requests submitted from a different host. *user-equivalence* is set to *false* by default. *false* means that usernames are not considered equivalent, and does not permit users cancel a print request submitted from a different host. If *user-equivalence* is set to *false*, print requests can only be cancelled by the users on the host on whichs the print prequest was generated or by the super-user on the print server.

Test Configuration Options

The following test configuration options (represented as *key=value* pairs) are supported:

`test-spooler-available=true|false`

Sets whether or not the protocol adaptor accepts connection requests to the test adaptor for the destination. `true` means that the protocol adaptor accepts connection requests to the test adaptor for the destination.

`test-spooler-available` is set to `true` by default. `false` means that the protocol adaptor does not accept connection requests to the test adaptor for the destination.

`test-log=dir`

Sets the location of the log file generated by the test translation module. Specify *dir* as an absolute pathname.

`test-dir=dir`

Sets the directory to be used during execution of the test translation module. Specify *dir* as an absolute pathname.

`test-access=true|false`

Sets whether or not the requesting client has access to the test translation module. `true` means that the requesting client has access to the test translation module.

`test-access` is set to `true` by default. `false` means that the the requesting client does not have access to the test translation module.

`test-accepting=true|false`

Sets whether or not the configured destination is accepting job submission requests. `true` means that the configured destination is accepting job submission requests.

`test-accepting` is set to `true` by default. `false` means that the configured destination is not accepting job submission requests.

`test-restart=true|false`

Sets whether or not a protocol request to restart the destination will be honored or return an error. `true` means that a protocol request to restart the destination will be honored. `test-restart` is set to `true` by default. `false` means that a protocol request to restart the destination return an error.

`test-submit=true|false`

Sets whether or not a protocol request to submit a job to a destination will be honored or return an error. `true` means that a protocol request to submit a job to a destination will be honored. `test-submit` is set to `true` by default. `false` means that a protocol request to submit a job to a destination will not be honored.

`test-show-queue-file=file`

Sets the name of the file whose contents are to be returned as the result of a status query. Specify *file* as an absolute pathname.

`test-cancel-cancel-file=file`

Sets the name of the file whose contents are returned as the result of a cancellation request. Specify *file* as an absolute pathname.

printers.conf(4)

Locating Destination Information

The print client commands and the print protocol adaptor locate destination information based on the “printers” database entry in the `/etc/nsswitch.conf` file. See `nsswitch.conf(4)`.

Locating the Personal Default Destination

The default destination is located differently depending on the command.

The `lp` command locates the default destination in the following order:

1. `lp` command's `-d destination` option.
2. `LPDEST` environment variable.
3. `PRINTER` environment variable.
4. `_default` destination in `$HOME/.printers`.
5. `_default` destination in `/etc/printers.conf`.
6. `_default` destination in FNS.

The `lpr`, `lpq`, and `lprm` commands locate the default destination in the following order:

1. `lpr` command's `-P destination` option.
2. `PRINTER` environment variable.
3. `LPDEST` environment variable.
4. `_default` destination in `$HOME/.printers`.
5. `_default` destination in `/etc/printers.conf`.
6. `_default` destination in FNS.

Locating the Interest List for `lpstat`, `lpget`, and `cancel`

The `lpget`, `lpstat`, and `cancel` commands locate the interest list in the following order:

1. `_all` list in `$HOME/.printers`.
2. `_all` list in `/etc/printers.conf`.
3. `_all` list in FNS.

Looking Up Destinations Using Atomic Names and FNS

Federated Naming Service (FNS) supports resolution of *composite* names spanning multiple naming systems. FNS supports several underlying naming services: NIS+, NIS, and files.

Atomic destination names are resolved using the search order specified by the “printers” database entry in the `/etc/nsswitch.conf` file. When the “xfn” service is configured in the “printers” database, the following Federated Name Service contexts are searched for the supplied name:

```
thisuser/service/printer,  
myorgunit/service/printer,
```

EXAMPLES**EXAMPLE 1** Setting the interest list

The following entry sets the interest list for the `lpget`, `lpstat` and `cancel` commands to `printer1`, `printer2` and `printer3`:

```
_all:all=printer1,printer2,printer3
```

EXAMPLE 2 Setting the server name

The following entry sets the server name to `server` and printer name to `ps_printer` for destinations `printer1` and `ps`. It does not generate protocol extensions.

```
printer1|ps:bsdaddr=server,ps_printer
```

EXAMPLE 3 Setting server name and destination name

The following entry sets the server name to `server` and destination name to `pcl_printer`, for destination `printer2`. It also generates Solaris protocol extensions.

```
printer2:bsdaddr=server,pcl_printer,Solaris
```

EXAMPLE 4 Setting server name and destination name with continuous search

The following entry sets the server name to `server` and destination name to `new_printer`, for destination `printer3`. It also sets the `printer3` to continue searching for configuration information to printer `another_printer`.

```
printer3:bsdaddr=server,new_printer:use=another_printer
```

EXAMPLE 5 Setting default destination

The following entry sets the default destination to continue searching for configuration information to destination `printer1`.

```
_default:use=printer1
```

FILES

```
/etc/printers.conf
  System configuration database.

$HOME/.printers
  User-configurable printer database.

printers.conf.byname (NIS)
  NIS version of /etc/printers.conf.

printers.org_dir (NIS+)
  NIS+ version of /etc/printers.conf.
```

printers.conf(4)

fns.ctx_dir.domain
FNS version of /etc/printers.conf.
*/usr/lib/print/bsd-adaptor/bsd_spooler.so**
Spooler translation modules.
/usr/lib/print/in.lpd
BSD print protocol adapter.

System Administration Guide: Basic Administration

NAME	proc – /proc, the process file system
DESCRIPTION	<p data-bbox="454 367 1438 609">/proc is a file system that provides access to the state of each process and light-weight process (lwp) in the system. The name of each entry in the /proc directory is a decimal number corresponding to a process-ID. These entries are themselves subdirectories. Access to process state is provided by additional files contained within each subdirectory; the hierarchy is described more completely below. In this document, “/proc file” refers to a non-directory file within the hierarchy rooted at /proc. The owner of each /proc file and subdirectory is determined by the user-ID of the process.</p> <p data-bbox="454 630 1438 756">/proc can be mounted on any mount point, in addition to the standard /proc mount point, and can be mounted several places at once. Such additional mounts are allowed in order to facilitate the confinement of processes to subtrees of the file system via chroot(1M) and yet allow such processes access to commands like ps(1).</p> <p data-bbox="454 777 1438 1050">Standard system calls are used to access /proc files: open(2), close(2), read(2), and write(2) (including readv(2), writev(2), pread(2), and pwrite(2)). Most files describe process state and can only be opened for reading. ctl and lwpctl (control) files permit manipulation of process state and can only be opened for writing. as (address space) files contain the image of the running process and can be opened for both reading and writing. An open for writing allows process control; a read-only open allows inspection but not control. In this document, we refer to the process as open for reading or writing if any of its associated /proc files is open for reading or writing.</p> <p data-bbox="454 1071 1438 1407">In general, more than one process can open the same /proc file at the same time. <i>Exclusive open</i> is an advisory mechanism provided to allow controlling processes to avoid collisions with each other. A process can obtain exclusive control of a target process, with respect to other cooperating processes, if it successfully opens any /proc file in the target process for writing (the as or ctl files, or the lwpctl file of any lwp) while specifying O_EXCL in the open(2). Such an open will fail if the target process is already open for writing (that is, if an as, ctl, or lwpctl file is already open for writing). There can be any number of concurrent read-only opens; O_EXCL is ignored on opens for reading. It is recommended that the first open for writing by a controlling process use the O_EXCL flag; multiple controlling processes usually result in chaos.</p> <p data-bbox="454 1428 1438 1617">If a process opens one of its own /proc files for writing, the open succeeds regardless of O_EXCL and regardless of whether some other process has the process open for writing. Self-opens do not count when another process attempts an exclusive open. (A process cannot exclude a debugger by opening itself for writing and the application of a debugger cannot prevent a process from opening itself.) All self-opens for writing are forced to be close-on-exec (see the F_SETFD operation of fcntl(2)).</p> <p data-bbox="454 1638 1438 1732">Data may be transferred from or to any locations in the address space of the traced process by applying lseek(2) to position the as file at the virtual address of interest followed by read(2) or write(2) (or by using pread(2) or pwrite(2) for the</p>

proc(4)

combined operation). The address-map file `/proc/pid/map` can be read to determine the accessible areas (mappings) of the address space. I/O transfers may span contiguous mappings. An I/O request extending into an unmapped area is truncated at the boundary. A write request beginning at an unmapped virtual address fails with EIO; a read request beginning at an unmapped virtual address returns zero (an end-of-file indication).

Information and control operations are provided through additional files. `<procfs.h>` contains definitions of data structures and message formats used with these files. Some of these definitions involve the use of sets of flags. The set types `sigset_t`, `fltset_t`, and `sysset_t` correspond, respectively, to signal, fault, and system call enumerations defined in `<sys/signal.h>`, `<sys/fault.h>`, and `<sys/syscall.h>`. Each set type is large enough to hold flags for its own enumeration. Although they are of different sizes, they have a common structure and can be manipulated by these macros:

```
prfillset(&set);           /* turn on all flags in set */
premptyset(&set);         /* turn off all flags in set */
praddset(&set, flag);     /* turn on the specified flag */
prdelset(&set, flag);     /* turn off the specified flag */
r = prismember(&set, flag); /* != 0 iff flag is turned on */
```

One of `prfillset()` or `premptyset()` must be used to initialize `set` before it is used in any other operation. `flag` must be a member of the enumeration corresponding to `set`.

Every process contains at least one *light-weight process*, or *lwp*. Each lwp represents a flow of execution that is independently scheduled by the operating system. All lwps in a process share its address space as well as many other attributes. Through the use of `lwpctl` and `ctl` files as described below, it is possible to affect individual lwps in a process or to affect all of them at once, depending on the operation.

When the process has more than one lwp, a representative lwp is chosen by the system for certain process status files and control operations. The representative lwp is a stopped lwp only if all of the process's lwps are stopped; is stopped on an event of interest only if all of the lwps are so stopped (excluding `PR_SUSPENDED` lwps); is in a `PR_REQUESTED` stop only if there are no other events of interest to be found; or, failing everything else, is in a `PR_SUSPENDED` stop (implying that the process is deadlocked). See the description of the `status` file for definitions of stopped states. See the `PCSTOP` control operation for the definition of "event of interest".

The representative lwp remains fixed (it will be chosen again on the next operation) as long as all of the lwps are stopped on events of interest or are in a `PR_SUSPENDED` stop and the `PCRUN` control operation is not applied to any of them.

When applied to the process control file, every `/proc` control operation that must act on an lwp uses the same algorithm to choose which lwp to act upon. Together with synchronous stopping (see `PCSET`), this enables a debugger to control a multiple-lwp

process using only the process-level status and control files if it so chooses. More fine-grained control can be achieved using the lwp-specific files.

The system supports two process data models, the traditional 32-bit data model in which ints, longs and pointers are all 32 bits wide (the ILP32 data model), and on some platforms the 64-bit data model in which longs and pointers, but not ints, are 64 bits in width (the LP64 data model). In the LP64 data model some system data types, notably `size_t`, `off_t`, `time_t` and `dev_t`, grow from 32 bits to 64 bits as well.

The `/proc` interfaces described here are available to both 32-bit and 64-bit controlling processes. However, many operations attempted by a 32-bit controlling process on a 64-bit target process will fail with `E_OVERFLOW` because the address space range of a 32-bit process cannot encompass a 64-bit process or because the data in some 64-bit system data type cannot be compressed to fit into the corresponding 32-bit type without loss of information. Operations that fail in this circumstance include reading and writing the address space, reading the address-map file, and setting the target process's registers. There is no restriction on operations applied by a 64-bit process to either a 32-bit or a 64-bit target processes.

The format of the contents of any `/proc` file depends on the data model of the observer (the controlling process), not on the data model of the target process. A 64-bit debugger does not have to translate the information it reads from a `/proc` file for a 32-bit process from 32-bit format to 64-bit format. However, it usually has to be aware of the data model of the target process. The `pr_dmodel` field of the `status` files indicates the target process's data model.

To help deal with system data structures that are read from 32-bit processes, a 64-bit controlling program can be compiled with the C preprocessor symbol `_SYSCALL32` defined before system header files are included. This makes explicit 32-bit fixed-width data structures (like `cstruct stat32`) visible to the 64-bit program. See `types32(3HEAD)`.

DIRECTORY STRUCTURE

At the top level, the directory `/proc` contains entries each of which names an existing process in the system. These entries are themselves directories. Except where otherwise noted, the files described below can be opened for reading only. In addition, if a process becomes a *zombie* (one that has exited but whose parent has not yet performed a `wait(2)` upon it), most of its associated `/proc` files disappear from the hierarchy; subsequent attempts to open them, or to read or write files opened before the process exited, will elicit the error `ENOENT`.

Although process state and consequently the contents of `/proc` files can change from instant to instant, a single `read(2)` of a `/proc` file is guaranteed to return a sane representation of state; that is, the read will be atomic with respect to the state of the process. No such guarantee applies to successive reads applied to a `/proc` file for a running process. In addition, atomicity is not guaranteed for I/O applied to the `as` (address-space) file for a running process or for a process whose address space contains memory shared by another running process.

proc(4)

STRUCTURE OF
/proc/pid

A number of structure definitions are used to describe the files. These structures may grow by the addition of elements at the end in future releases of the system and it is not legitimate for a program to assume that they will not.

A given directory */proc/pid* contains the following entries. A process can use the invisible alias */proc/self* if it wishes to open one of its own */proc* files (invisible in the sense that the name "self" does not appear in a directory listing of */proc* obtained from *ls(1)*, *getdents(2)*, or *readdir(3C)*).

- as** Contains the address-space image of the process; it can be opened for both reading and writing. *lseek(2)* is used to position the file at the virtual address of interest and then the address space can be examined or changed through *read(2)* or *write(2)* (or by using *pread(2)* or *pwrite(2)* for the combined operation).
- ctl** A write-only file to which structured messages are written directing the system to change some aspect of the process's state or control its behavior in some way. The seek offset is not relevant when writing to this file. Individual lwps also have associated *lwpctl* files in the *lwp* subdirectories. A control message may be written either to the process's *ctl* file or to a specific *lwpctl* file with operation-specific effects. The effect of a control message is immediately reflected in the state of the process visible through appropriate status and information files. The types of control messages are described in detail later. See CONTROL MESSAGES.
- status** Contains state information about the process and the representative lwp. The file contains a *pstatus* structure which contains an embedded *lwpstatus* structure for the representative lwp, as follows:

```
typedef struct pstatus {
    int pr_flags;           /* flags (see below) */
    int pr_nlwp;           /* number of lwps in the process */
    pid_t pr_pid;          /* process id */
    pid_t pr_ppid;         /* parent process id */
    pid_t pr_pgid;         /* process group id */
    pid_t pr_sid;          /* session id */
    id_t pr_aslwpid;       /* obsolete */
    id_t pr_agentid;       /* lwp-id of the agent lwp, if any */
    sigset_t pr_sigpend;   /* set of process pending signals */
    uintptr_t pr_brkbase;  /* virtual address of the process heap */
    size_t pr_brksize;     /* size of the process heap, in bytes */
    uintptr_t pr_stkbase;  /* virtual address of the process stack */
    size_t pr_stksize;     /* size of the process stack, in bytes */
    timestruc_t pr_utime;  /* process user cpu time */
    timestruc_t pr_stime;  /* process system cpu time */
    timestruc_t pr_cutime; /* sum of children's user times */
    timestruc_t pr_cstime; /* sum of children's system times */
    sigset_t pr_sigtrace;  /* set of traced signals */
    fltset_t pr_fltrtrace; /* set of traced faults */
    sysset_t pr_sysentry;  /* set of system calls traced on entry */
    sysset_t pr_sysexit;   /* set of system calls traced on exit */
    char pr_dmodel;        /* data model of the process */
    taskid_t pr_taskid;    /* task id */
    projid_t pr_projid;    /* project id */
};
```

```

    lwpstatus_t pr_lwp;          /* status of the representative lwp */
} pstatus_t;

```

`pr_flags` is a bit-mask holding the following process flags. For convenience, it also contains the lwp flags for the representative lwp, described later.

<code>PR_ISSYS</code>	process is a system process (see <code>PCSTOP</code>).
<code>PR_VFORKP</code>	process is the parent of a vforked child (see <code>PCWATCH</code>).
<code>PR_FORK</code>	process has its inherit-on-fork mode set (see <code>PCSET</code>).
<code>PR_RLC</code>	process has its run-on-last-close mode set (see <code>PCSET</code>).
<code>PR_KLC</code>	process has its kill-on-last-close mode set (see <code>PCSET</code>).
<code>PR_ASYNC</code>	process has its asynchronous-stop mode set (see <code>PCSET</code>).
<code>PR_MSACCT</code>	process has microstate accounting enabled (see <code>PCSET</code>).
<code>PR_MSFOK</code>	process microstate accounting is inherited on fork (see <code>PCSET</code>).
<code>PR_BPTADJ</code>	process has its breakpoint adjustment mode set (see <code>PCSET</code>).
<code>PR_PTRACE</code>	process has its ptrace-compatibility mode set (see <code>PCSET</code>).

`pr_nlwp` is the total number of lwps in the process.

`pr_pid`, `pr_ppid`, `pr_pgid`, and `pr_sid` are, respectively, the process ID, the ID of the process's parent, the process's process group ID, and the process's session ID.

`pr_aslwpid` is obsolete and is always zero.

`pr_agentid` is the lwp-ID for the `/proc` agent lwp (see the `PCAGENT` control operation). It is zero if there is no agent lwp in the process.

`pr_sigpend` identifies asynchronous signals pending for the process.

`pr_brkbase` is the virtual address of the process heap and `pr_brksize` is its size in bytes. The address formed by the sum of these values is the process break (see `brk(2)`). `pr_stkbase` and `pr_stksize` are, respectively, the virtual address of the process stack and its size in bytes. (Each lwp runs on a separate stack; the distinguishing characteristic of the process stack is that the operating system will grow it when necessary.)

`pr_utime`, `pr_stime`, `pr_cutime`, and `pr_cstime` are, respectively, the user CPU and system CPU time consumed by the process, and the cumulative user CPU and system CPU time consumed by the process's children, in seconds and nanoseconds.

`pr_sigtrace` and `pr_fltrace` contain, respectively, the set of signals and the set of hardware faults that are being traced (see `PCSTRACE` and `PCSFAULT`).

`pr_sysentry` and `pr_sysexit` contain, respectively, the sets of system calls being traced on entry and exit (see `PCSENTRY` and `PCSEXIT`).

proc(4)

`pr_dmodel` indicates the data model of the process. Possible values are:

<code>PR_MODEL_ILP32</code>	process data model is ILP32.
<code>PR_MODEL_LP64</code>	process data model is LP64.
<code>PR_MODEL_NATIVE</code>	process data model is native.

The constant `PR_MODEL_NATIVE` reflects the data model of the controlling process, *that is*, its value is `PR_MODEL_ILP32` or `PR_MODEL_LP64` according to whether the controlling process has been compiled as a 32-bit program or a 64-bit program, respectively.

`pr_lwp` contains the status information for the representative lwp:

```
typedef struct lwpstatus {
    int pr_flags;           /* flags (see below) */
    id_t pr_lwpid;         /* specific lwp identifier */
    short pr_why;          /* reason for lwp stop, if stopped */
    short pr_what;         /* more detailed reason */
    short pr_cursig;       /* current signal, if any */
    siginfo_t pr_info;     /* info associated with signal or fault */
    sigset_t pr_lwppend;   /* set of signals pending to the lwp */
    sigset_t pr_lwphold;   /* set of signals blocked by the lwp */
    struct sigaction pr_action; /* signal action for current signal */
    stack_t pr_altstack;   /* alternate signal stack info */
    uintptr_t pr_oldcontext; /* address of previous ucontext */
    short pr_syscall;      /* system call number (if in syscall) */
    short pr_nsysarg;      /* number of arguments to this syscall */
    int pr_errno;          /* errno for failed syscall */
    long pr_sysarg[PRSYSARGS]; /* arguments to this syscall */
    long pr_rval1;         /* primary syscall return value */
    long pr_rval2;         /* second syscall return value, if any */
    char pr_clname[PRCLSZ]; /* scheduling class name */
    timestruc_t pr_tstamp; /* real-time time stamp of stop */
    ulong_t pr_instr;      /* current instruction */
    prgregset_t pr_reg;    /* general registers */
    prfpregset_t pr_fpreg; /* floating-point registers */
} lwpstatus_t;
```

`pr_flags` is a bit-mask holding the following lwp flags. For convenience, it also contains the process flags, described previously.

<code>PR_STOPPED</code>	lwp is stopped.
<code>PR_ISTOP</code>	lwp is stopped on an event of interest (see <code>PCSTOP</code>).
<code>PR_DSTOP</code>	lwp has a stop directive in effect (see <code>PCSTOP</code>).
<code>PR_STEP</code>	lwp has a single-step directive in effect (see <code>PCRUN</code>).
<code>PR_ASLEEP</code>	lwp is in an interruptible sleep within a system call.
<code>PR_PCINVAL</code>	lwp's current instruction (<code>pr_instr</code>) is undefined.
<code>PR_ASLWP</code>	this flag is obsolete and is never set..

`PR_AGENT` this is the `/proc` agent lwp for the process.

`pr_lwpid` names the specific lwp.

`pr_why` and `pr_what` together describe, for a stopped lwp, the reason for the stop. Possible values of `pr_why` and the associated `pr_what` are:

`PR_REQUESTED` indicates that the stop occurred in response to a stop directive, normally because `PCSTOP` was applied or because another lwp stopped on an event of interest and the asynchronous-stop flag (see `PCSET`) was not set for the process. `pr_what` is unused in this case.

`PR_SIGNALLED` indicates that the lwp stopped on receipt of a signal (see `PCSTRACE`); `pr_what` holds the signal number that caused the stop (for a newly-stopped lwp, the same value is in `pr_cursig`).

`PR_FAULTED` indicates that the lwp stopped on incurring a hardware fault (see `PCSFAULT`); `pr_what` holds the fault number that caused the stop.

`PR_SYSENTRY`

`PR_SYSEXIT` indicate a stop on entry to or exit from a system call (see `PCSENTRY` and `PCSEXIT`); `pr_what` holds the system call number.

`PR_JOBCONTROL` indicates that the lwp stopped due to the default action of a job control stop signal (see `sigaction(2)`); `pr_what` holds the stopping signal number.

`PR_SUSPENDED` indicates that the lwp stopped due to internal synchronization of lwps within the process. `pr_what` is unused in this case.

`pr_cursig` names the current signal, that is, the next signal to be delivered to the lwp, if any. `pr_info`, when the lwp is in a `PR_SIGNALLED` or `PR_FAULTED` stop, contains additional information pertinent to the particular signal or fault (see `<sys/signinfo.h>`).

`pr_lwppend` identifies any synchronous or directed signals pending for the lwp.

`pr_lwphold` identifies those signals whose delivery is being blocked by the lwp (the signal mask).

`pr_action` contains the signal action information pertaining to the current signal (see `sigaction(2)`); it is undefined if `pr_cursig` is zero. `pr_altstack` contains the alternate signal stack information for the lwp (see `sigaltstack(2)`).

`pr_oldcontext`, if not zero, contains the address on the lwp stack of a `ucontext` structure describing the previous user-level context (see `ucontext(3HEAD)`). It is non-zero only if the lwp is executing in the context of a signal handler.

`pr_syscall` is the number of the system call, if any, being executed by the lwp; it is non-zero if and only if the lwp is stopped on `PR_SYSENTRY` or `PR_SYSEXIT`, or is

proc(4)

asleep within a system call (`PR_ASLEEP` is set). If `pr_syscall` is non-zero, `pr_nsysarg` is the number of arguments to the system call and `pr_sysarg` contains the actual arguments.

`pr_rval1`, `pr_rval2`, and `pr_errno` are defined only if the lwp is stopped on `PR_SYSEXIT` or if the `PR_VFORKP` flag is set. If `pr_errno` is zero, `pr_rval1` and `pr_rval2` contain the return values from the system call. Otherwise, `pr_errno` contains the error number for the failing system call (see `<sys/errno.h>`).

`pr_clname` contains the name of the lwp's scheduling class.

`pr_tstamp`, if the lwp is stopped, contains a time stamp marking when the lwp stopped, in real time seconds and nanoseconds since an arbitrary time in the past.

`pr_instr` contains the machine instruction to which the lwp's program counter refers. The amount of data retrieved from the process is machine-dependent. On SPARC based machines, it is a 32-bit word. On IA based machines, it is a single byte. In general, the size is that of the machine's smallest instruction. If `PR_PCINVAL` is set, `pr_instr` is undefined; this occurs whenever the lwp is not stopped or when the program counter refers to an invalid virtual address.

`pr_reg` is an array holding the contents of a stopped lwp's general registers.

SPARC On SPARC-based machines, the predefined constants `R_G0 ... R_G7`, `R_O0 ... R_O7`, `R_L0 ... R_L7`, `R_I0 ... R_I7`, `R_PC`, `R_nPC`, and `R_Y` can be used as indices to refer to the corresponding registers; previous register windows can be read from their overflow locations on the stack (however, see the `gwindows` file in the `/proc/pid/lwp/lwpid` subdirectory).

SPARC V8 (32-bit) For SPARC V8 (32-bit) controlling processes, the predefined constants `R_PSR`, `R_WIM`, and `R_TBR` can be used as indices to refer to the corresponding special registers. For SPARC V9 (64-bit) controlling processes, the predefined constants `R_CCR`, `R_ASI`, and `R_FPRS` can be used as indices to refer to the corresponding special registers.

IA On IA based machines, the predefined constants `SS`, `UESP`, `EFL`, `CS`, `EIP`, `ERR`, `TRAPNO`, `EAX`, `ECX`, `EDX`, `EBX`, `ESP`, `EBP`, `ESI`, `EDI`, `DS`, `ES`, `FS`, and `GS` can be used as indices to refer to the corresponding registers.

`pr_fpreg` is a structure holding the contents of the floating-point registers.

SPARC registers, both general and floating-point, as seen by a 64-bit controlling process are the V9 versions of the registers, even if the target process is a 32-bit (V8) process. V8 registers are a subset of the V9 registers.

If the lwp is not stopped, all register values are undefined.

psinfo Contains miscellaneous information about the process and the representative lwp needed by the `ps(1)` command. `psinfo` is accessible after a process becomes a *zombie*. The file contains a `psinfo` structure which contains an embedded `lwpsinfo` structure for the representative lwp, as follows:

```
typedef struct psinfo {
    int pr_flag;           /* process flags */
    int pr_nlwp;          /* number of lwps in the process */
    pid_t pr_pid;         /* process id */
    pid_t pr_ppid;        /* process id of parent */
    pid_t pr_pgid;        /* process id of process group leader */
    pid_t pr_sid;         /* session id */
    uid_t pr_uid;         /* real user id */
    uid_t pr_euid;        /* effective user id */
    gid_t pr_gid;         /* real group id */
    gid_t pr_egid;        /* effective group id */
    uintptr_t pr_addr;    /* address of process */
    size_t pr_size;       /* size of process image in Kbytes */
    size_t pr_rssize;     /* resident set size in Kbytes */
    dev_t pr_ttydev;      /* controlling tty device (or PRNODEV) */
    ushort_t pr_pctcpu;   /* % of recent cpu time used by all lwps */
    ushort_t pr_pctmem;   /* % of system memory used by process */
    timestruc_t pr_start; /* process start time, from the epoch */
    timestruc_t pr_time;  /* cpu time for this process */
    timestruc_t pr_ctime; /* cpu time for reaped children */
    taskid_t pr_taskid;   /* task id */
    projid_t pr_projid;   /* project id */
    char pr_fname[PRFNSZ]; /* name of exec'ed file */
    char pr_psargs[PRARGSZ]; /* initial characters of arg list */
    int pr_wstat;         /* if zombie, the wait() status */
    int pr_argc;          /* initial argument count */
    uintptr_t pr_argv;    /* address of initial argument vector */
    uintptr_t pr_envp;    /* address of initial environment vector */
    char pr_dmodel;       /* data model of the process */
    lwpsinfo_t pr_lwp;    /* information for representative lwp */
} psinfo_t;
```

Some of the entries in `psinfo`, such as `pr_flag` and `pr_addr`, refer to internal kernel data structures and should not be expected to retain their meanings across different versions of the operating system.

`pr_pctcpu` and `pr_pctmem` are 16-bit binary fractions in the range 0.0 to 1.0 with the binary point to the right of the high-order bit (1.0 == 0x8000). `pr_pctcpu` is the summation over all lwps in the process.

`pr_lwp` contains the `ps(1)` information for the representative lwp. If the process is a *zombie*, `pr_nlwp` and `pr_lwp.pr_lwpid` are zero and the other fields of `pr_lwp` are undefined:

```
typedef struct lwpsinfo {
    int pr_flag;           /* lwp flags */
    id_t pr_lwpid;         /* lwp id */
    uintptr_t pr_addr;     /* internal address of lwp */
}
```

proc(4)

```
uintptr_t pr_wchan;      /* wait addr for sleeping lwp */
char pr_stype;           /* synchronization event type */
char pr_state;          /* numeric lwp state */
char pr_sname;          /* printable character for pr_state */
char pr_nice;           /* nice for cpu usage */
short pr_syscall;       /* system call number (if in syscall) */
char pr_oldpri;         /* pre-SVR4, low value is high priority */
char pr_cpu;            /* pre-SVR4, cpu usage for scheduling */
int pr_pri;             /* priority, high value = high priority */
ushort_t pr_pctcpu;     /* % of recent cpu time used by this lwp */
timestruc_t pr_start;   /* lwp start time, from the epoch */
timestruc_t pr_time;    /* cpu time for this lwp */
char pr_cname[PRCLSZ];  /* scheduling class name */
char pr_name[PRFNSZ];   /* name of system lwp */
processorid_t pr_onpro;  /* processor which last ran this lwp */
processorid_t pr_bindpro; /* processor to which lwp is bound */
psetid_t pr_bindpset;   /* processor set to which lwp is bound */
} lwpsinfo_t;
```

Some of the entries in `lwpsinfo`, such as `pr_flag`, `pr_addr`, `pr_wchan`, `pr_stype`, `pr_state`, and `pr_name`, refer to internal kernel data structures and should not be expected to retain their meanings across different versions of the operating system.

`pr_pctcpu` is a 16-bit binary fraction, as described above. It represents the CPU time used by the specific lwp. On a multi-processor machine, the maximum value is $1/N$, where N is the number of CPUs.

cred Contains a description of the credentials associated with the process:

```
typedef struct prcred {
    uid_t pr_euid;      /* effective user id */
    uid_t pr_ruid;      /* real user id */
    uid_t pr_suid;      /* saved user id (from exec) */
    gid_t pr_egid;      /* effective group id */
    gid_t pr_rgid;      /* real group id */
    gid_t pr_sgid;      /* saved group id (from exec) */
    int pr_ngroups;     /* number of supplementary groups */
    gid_t pr_groups[1]; /* array of supplementary groups */
} prcred_t;
```

The array of associated supplementary groups in `pr_groups` is of variable length; the `cred` file contains all of the supplementary groups. `pr_ngroups` indicates the number of supplementary groups. (See also the `PCSCRED` control operation.)

sigact Contains an array of `sigaction` structures describing the current dispositions of all signals associated with the traced process (see `sigaction(2)`). Signal numbers are displaced by 1 from array indices, so that the action for signal number n appears in position $n-1$ of the array.

auxv Contains the initial values of the process's aux vector in an array of `auxv_t` structures (see `<sys/auxv.h>`). The values are those that were passed by the operating system as startup information to the dynamic linker.

ldt This file exists only on IA based machines. It is non-empty only if the process has established a local descriptor table (LDT). If non-empty, the file contains the array of currently active LDT entries in an array of elements of type `struct ssd`, defined in `<sys/sysi86.h>`, one element for each active LDT entry.

map Contains information about the virtual address map of the process. The file contains an array of `prmap` structures, each of which describes a contiguous virtual address region in the address space of the traced process:

```
typedef struct prmap {
    uintptr_t pr_vaddr;           /* virtual address of mapping */
    size_t pr_size;              /* size of mapping in bytes */
    char pr_mapname[PRMAPSZ];    /* name in /proc/pid/object */
    offset_t pr_offset;          /* offset into mapped object, if any */
    int pr_mflags;               /* protection and attribute flags */
    int pr_pagesize;             /* pagesize for this mapping in bytes */
    int pr_shmid;                /* SysV shared memory identifier */
} prmap_t;
```

`pr_vaddr` is the virtual address of the mapping within the traced process and `pr_size` is its size in bytes. `pr_mapname`, if it does not contain a null string, contains the name of a file in the `object` directory (see below) that can be opened read-only to obtain a file descriptor for the mapped file associated with the mapping. This enables a debugger to find object file symbol tables without having to know the real path names of the executable file and shared libraries of the process. `pr_offset` is the 64-bit offset within the mapped file (if any) to which the virtual address is mapped.

`pr_mflags` is a bit-mask of protection and attribute flags:

<code>MA_READ</code>	mapping is readable by the traced process.
<code>MA_WRITE</code>	mapping is writable by the traced process.
<code>MA_EXEC</code>	mapping is executable by the traced process.
<code>MA_SHARED</code>	mapping changes are shared by the mapped object.
<code>MA_ISM</code>	mapping is intimate shared memory (shared MMU resources).

A contiguous area of the address space having the same underlying mapped object may appear as multiple mappings due to varying read, write, and execute attributes. The underlying mapped object does not change over the range of a single mapping. An I/O operation to a mapping marked `MA_SHARED` fails if applied at a virtual address not corresponding to a valid page in the underlying mapped object. A write to a `MA_SHARED` mapping that is not marked `MA_WRITE` fails. Reads and writes to private mappings always succeed. Reads and writes to unmapped addresses fail.

`pr_pagesize` is the page size for the mapping, currently always the system pagesize.

`pr_shmid` is the shared memory identifier, if any, for the mapping. Its value is `-1` if the mapping is not System V shared memory. See `shmget(2)`.

proc(4)

rmap	<p>Contains information about the reserved address ranges of the process. The file contains an array of <code>prmap</code> structures, as defined above for the <code>map</code> file. Each structure describes a contiguous virtual address region in the address space of the traced process that is reserved by the system in the sense that an <code>mmap(2)</code> system call that does not specify <code>MAP_FIXED</code> will not use any part of it for the new mapping. Examples of such reservations include the address ranges reserved for the process stack and the individual thread stacks of a multi-threaded process.</p>
cwd	<p>A symbolic link to the process's current working directory (see <code>chdir(2)</code>). A <code>readlink(2)</code> of <code>/proc/pid/cwd</code> yields a null string. However, it can be opened, listed, and searched as a directory and can be the target of <code>chdir(2)</code>.</p>
root	<p>A symbolic link to the process's root directory. <code>/proc/pid/root</code> can differ from the system root directory if the process or one of its ancestors executed <code>chroot(2)</code> as super-user. It has the same semantics as <code>/proc/pid/cwd</code>.</p>
fd	<p>A directory containing references to the open files of the process. Each entry is a decimal number corresponding to an open file descriptor in the process.</p> <p>If an entry refers to a regular file, it can be opened with normal file system semantics but, to ensure that the controlling process cannot gain greater access than the controlled process, with no file access modes other than its read/write open modes in the controlled process. If an entry refers to a directory, it appears as a symbolic link and can be accessed with the same semantics as <code>/proc/pid/cwd</code>. An attempt to open any other type of entry fails with <code>EACCES</code>.</p>
object	<p>A directory containing read-only files with names corresponding to the <code>pr_mapname</code> entries in the <code>map</code> and <code>pagedata</code> files. Opening such a file yields a file descriptor for the underlying mapped file associated with an address-space mapping in the process. The file name <code>a.out</code> appears in the directory as an alias for the process's executable file.</p> <p>The <code>object</code> directory makes it possible for a controlling process to gain access to the object file and any shared libraries (and consequently the symbol tables) without having to know the actual path names of the executable files.</p>
pagedata	<p>Opening the page data file enables tracking of address space references and modifications on a per-page basis.</p> <p>A <code>read(2)</code> of the page data file descriptor returns structured page data and atomically clears the page data maintained for the file by the system. That is to say, each read returns data collected since the last read; the first read returns data collected since the file was opened. When the call completes, the read buffer contains the following structure as its header and thereafter contains a number of section header structures and associated byte arrays that must be accessed by walking linearly through the buffer.</p> <pre>typedef struct prpageheader { timestruc_t pr_tstamp; /* real time stamp, time of read() */ ulong_t pr_nmap; /* number of address space mappings */ }</pre>

```

    ulong_t pr_npage;      /* total number of pages */
} prpageheader_t;

```

The header is followed by `pr_nmap` `prasmap` structures and associated data arrays. The `prasmap` structure contains the following elements:

```

typedef struct prasmap {
    uintptr_t pr_vaddr;      /* virtual address of mapping */
    ulong_t pr_npage;      /* number of pages in mapping */
    char pr_mapname[PRMAPSZ]; /* name in /proc/pid/object */
    offset_t pr_offset;     /* offset into mapped object, if any */
    int pr_mflags;         /* protection and attribute flags */
    int pr_pagesize;       /* pagesize for this mapping in bytes */
    int pr_shmid;          /* SysV shared memory identifier */
} prasmap_t;

```

Each section header is followed by `pr_npage` bytes, one byte for each page in the mapping, plus 0-7 null bytes at the end so that the next `prasmap` structure begins on an eight-byte aligned boundary. Each data byte may contain these flags:

```

PG_REFERENCED           page has been referenced.
PG_MODIFIED              page has been modified.

```

If the read buffer is not large enough to contain all of the page data, the read fails with `E2BIG` and the page data is not cleared. The required size of the read buffer can be determined through `fstat(2)`. Application of `lseek(2)` to the page data file descriptor is ineffective; every read starts from the beginning of the file. Closing the page data file descriptor terminates the system overhead associated with collecting the data.

More than one page data file descriptor for the same process can be opened, up to a system-imposed limit per traced process. A read of one does not affect the data being collected by the system for the others. An open of the page data file will fail with `ENOMEM` if the system-imposed limit would be exceeded.

watch Contains an array of `prwatch` structures, one for each watched area established by the `PCWATCH` control operation. See `PCWATCH` for details.

usage Contains process usage information described by a `prusage` structure which contains at least the following fields:

```

typedef struct prusage {
    id_tpr_lwpid;          /* lwp id. 0: process or defunct */
    int pr_count;         /* number of contributing lwps */
    timestruc_t pr_tstamp; /* real time stamp, time of read() */
    timestruc_t pr_create; /* process/lwp creation time stamp */
    timestruc_t pr_term;   /* process/lwp termination time stamp */
    timestruc_t pr_rtime;  /* total lwp real (elapsed) time */
    timestruc_t pr_utime;  /* user level CPU time */
    timestruc_t pr_stime;  /* system call CPU time */
    timestruc_t pr_ttime;  /* other system trap CPU time */
    timestruc_t pr_tftime; /* text page fault sleep time */
    timestruc_t pr_dftime; /* data page fault sleep time */
    timestruc_t pr_kftime; /* kernel page fault sleep time */
}

```

proc(4)

```
    timestruc_t pr_ltime;      /* user lock wait sleep time */
    timestruc_t pr_slptime;    /* all other sleep time */
    timestruc_t pr_wtime;      /* wait-cpu (latency) time */
    timestruc_t pr_stoptime;   /* stopped time */
    ulong_t pr_minf;           /* minor page faults */
    ulong_t pr_majf;           /* major page faults */
    ulong_t pr_nswap;          /* swaps */
    ulong_t pr_inblk;           /* input blocks */
    ulong_t pr_oublk;          /* output blocks */
    ulong_t pr_msnd;           /* messages sent */
    ulong_t pr_mrcv;           /* messages received */
    ulong_t pr_sigs;           /* signals received */
    ulong_t pr_vctx;           /* voluntary context switches */
    ulong_t pr_ictx;           /* involuntary context switches */
    ulong_t pr_sysc;           /* system calls */
    ulong_t pr_ioch;           /* chars read and written */
} prusage_t;
```

If microstate accounting has not been enabled for the process (see the `PR_MSACCT` flag for the `PCSET` operation, below), the usage file contains only an estimate of times spent in the various states. The usage file is accessible after a process becomes a *zombie*.

lstatus Contains a `prheader` structure followed by an array of `lwpstatus` structures, one for each `lwp` in the process (see also `/proc/pid/lwp/lwpid/lwpstatus`, below). The `prheader` structure describes the number and size of the array entries that follow.

```
typedef struct prheader {
    long pr_nent;              /* number of entries */
    size_t pr_entsize;        /* size of each entry, in bytes */
} prheader_t;
```

The `lwpstatus` structure may grow by the addition of elements at the end in future releases of the system. Programs must use `pr_entsize` in the file header to index through the array. These comments apply to all `/proc` files that include a `prheader` structure (`lpsinfo` and `lusage`, below).

lpsinfo Contains a `prheader` structure followed by an array of `lwpsinfo` structures, one for each `lwp` in the process. (See also `/proc/pid/lwp/lwpid/lwpsinfo`, below.)

lusage Contains a `prheader` structure followed by an array of `prusage` structures, one for each `lwp` in the process plus an additional element at the beginning that contains the summation over all defunct `lwps` (`lwps` that once existed but no longer exist in the process). Excluding the `pr_lwpid`, `pr_tstamp`, `pr_create`, and `pr_term` entries, the entry-by-entry summation over all these structures is the definition of the process usage information obtained from the usage file. (See also `/proc/pid/lwp/lwpid/lwusage`, below.)

lwp A directory containing entries each of which names an `lwp` within the process. These entries are themselves directories containing additional files as described below.

STRUCTURE OF `/proc/pid/lwp/ lwpid`

A given directory `/proc/pid/lwp/lwpid` contains the following entries:

lwpctl	Write-only control file. The messages written to this file affect the specific lwp rather than the representative lwp, as is the case for the process's <code>ctl</code> file.
lwpstatus	lwp-specific state information. This file contains the <code>lwpstatus</code> structure for the specific lwp as described above for the representative lwp in the process's <code>status</code> file.
lwpsinfo	lwp-specific <code>ps(1)</code> information. This file contains the <code>lwpsinfo</code> structure for the specific lwp as described above for the representative lwp in the process's <code>psinfo</code> file.
lwpusage	This file contains the <code>prusage</code> structure for the specific lwp as described above for the process's <code>usage</code> file.
gwindows	This file exists only on SPARC based machines. If it is non-empty, it contains a <code>gwindows_t</code> structure, defined in <code><sys/regset.h></code> , with the values of those SPARC register windows that could not be stored on the stack when the lwp stopped. Conditions under which register windows are not stored on the stack are: the stack pointer refers to nonexistent process memory or the stack pointer is improperly aligned. If the lwp is not stopped or if there are no register windows that could not be stored on the stack, the file is empty (the usual case).
xregs	Extra state registers. The extra state register set is architecture dependent; this file is empty if the system does not support extra state registers. If the file is non-empty, it contains an architecture dependent structure of type <code>prxregset_t</code> , defined in <code><procfs.h></code> , with the values of the lwp's extra state registers. If the lwp is not stopped, all register values are undefined. See also the <code>PCSXREG</code> control operation, below.
asrs	This file exists only for 64-bit SPARC V9 processes. It contains an <code>asrset_t</code> structure, defined in <code><sys/regset.h></code> , containing the values of the lwp's platform-dependent ancillary state registers. If the lwp is not stopped, all register values are undefined. See also the <code>PCSASRS</code> control operation, below.
CONTROL MESSAGES	<p>Process state changes are effected through messages written to a process's <code>ctl</code> file or to an individual lwp's <code>lwpctl</code> file. All control messages consist of a <code>long</code> that names the specific operation followed by additional data containing the operand, if any.</p> <p>Multiple control messages may be combined in a single <code>write(2)</code> (or <code>writew(2)</code>) to a control file, but no partial writes are permitted. That is, each control message, operation code plus operand, if any, must be presented in its entirety to the <code>write(2)</code> and not in pieces over several system calls. If a control operation fails, no subsequent operations contained in the same <code>write(2)</code> are attempted.</p> <p>Descriptions of the allowable control messages follow. In all cases, writing a message to a control file for a process or lwp that has terminated elicits the error <code>ENOENT</code>.</p>
PCSTOP PCDSTOP PCWSTOP PCTWSTOP	When applied to the process control file, <code>PCSTOP</code> directs all lwps to stop and waits for them to stop, <code>PCDSTOP</code> directs all lwps to stop without waiting for them to stop, and <code>PCWSTOP</code> simply waits for all lwps to stop. When applied to an lwp control file, <code>PCSTOP</code> directs the specific lwp to stop and waits until it has stopped, <code>PCDSTOP</code>

proc(4)

directs the specific lwp to stop without waiting for it to stop, and PCWSTOP simply waits for the specific lwp to stop. When applied to an lwp control file, PCSTOP and PCWSTOP complete when the lwp stops on an event of interest, immediately if already so stopped; when applied to the process control file, they complete when every lwp has stopped either on an event of interest or on a PR_SUSPENDED stop.

PCTWSTOP is identical to PCWSTOP except that it enables the operation to time out, to avoid waiting forever for a process or lwp that may never stop on an event of interest. PCTWSTOP takes a long operand specifying a number of milliseconds; the wait will terminate successfully after the specified number of milliseconds even if the process or lwp has not stopped; a timeout value of zero makes the operation identical to PCWSTOP.

An “event of interest” is either a PR_REQUESTED stop or a stop that has been specified in the process’s tracing flags (set by PCSTRACE, PCSFAULT, PCSENTRY, and PCSEXIT). PR_JOBCONTROL and PR_SUSPENDED stops are specifically not events of interest. (An lwp may stop twice due to a stop signal, first showing PR_SIGNALLED if the signal is traced and again showing PR_JOBCONTROL if the lwp is set running without clearing the signal.) If PCSTOP or PCDSTOP is applied to an lwp that is stopped, but not on an event of interest, the stop directive takes effect when the lwp is restarted by the competing mechanism. At that time, the lwp enters a PR_REQUESTED stop before executing any user-level code.

A write of a control message that blocks is interruptible by a signal so that, for example, an alarm(2) can be set to avoid waiting forever for a process or lwp that may never stop on an event of interest. If PCSTOP is interrupted, the lwp stop directives remain in effect even though the write(2) returns an error. (Use of PCTWSTOP with a non-zero timeout is recommended over PCWSTOP with an alarm(2).)

A system process (indicated by the PR_ISSYS flag) never executes at user level, has no user-level address space visible through /proc, and cannot be stopped. Applying one of these operations to a system process or any of its lwps elicits the error EBUSY.

PCRUN Make an lwp runnable again after a stop. This operation takes a long operand containing zero or more of the following flags:

- | | |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRCSIG | clears the current signal, if any (see PCCSIG). |
| PRCFAULT | clears the current fault, if any (see PCCFAULT). |
| PRSTEP | directs the lwp to execute a single machine instruction. On completion of the instruction, a trace trap occurs. If FLTTRACE is being traced, the lwp stops; otherwise, it is sent SIGTRAP. If SIGTRAP is being traced and is not blocked, the lwp stops. When the lwp stops on an event of interest, the single-step directive is cancelled, even if the stop occurs before the instruction is executed. This operation requires hardware and operating system support |

and may not be implemented on all processors. It is implemented on SPARC and IA based machines.

PR SABORT is meaningful only if the lwp is in a `PR_SYSENTRY` stop or is marked `PR_ASLEEP`; it instructs the lwp to abort execution of the system call (see `PCSENTRY` and `PCSEXIT`).

PR STOP directs the lwp to stop again as soon as possible after resuming execution (see `PCDSTOP`). In particular, if the lwp is stopped on `PR_SIGNALED` or `PR_FAULTED`, the next stop will show `PR_REQUESTED`, no other stop will have intervened, and the lwp will not have executed any user-level code.

When applied to an lwp control file, `PCRUN` clears any outstanding directed-stop request and makes the specific lwp runnable. The operation fails with `EBUSY` if the specific lwp is not stopped on an event of interest or has not been directed to stop or if the agent lwp exists and this is not the agent lwp (see `PCAGENT`).

When applied to the process control file, a representative lwp is chosen for the operation as described for `/proc/pid/status`. The operation fails with `EBUSY` if the representative lwp is not stopped on an event of interest or has not been directed to stop or if the agent lwp exists. If `PRSTEP` or `PRSTOP` was requested, the representative lwp is made runnable and its outstanding directed-stop request is cleared; otherwise all outstanding directed-stop requests are cleared and, if it was stopped on an event of interest, the representative lwp is marked `PR_REQUESTED`. If, as a consequence, all lwps are in the `PR_REQUESTED` or `PR_SUSPENDED` stop state, all lwps showing `PR_REQUESTED` are made runnable.

PCSTRACE Define a set of signals to be traced in the process. The receipt of one of these signals by an lwp causes the lwp to stop. The set of signals is defined using an operand `sigset_t` contained in the control message. Receipt of `SIGKILL` cannot be traced; if specified, it is silently ignored.

If a signal that is included in an lwp's held signal set (the signal mask) is sent to the lwp, the signal is not received and does not cause a stop until it is removed from the held signal set, either by the lwp itself or by setting the held signal set with `PCSHOLD`.

PCCSIG The current signal, if any, is cleared from the specific or representative lwp.

PCSSIG The current signal and its associated signal information for the specific or representative lwp are set according to the contents of the operand `siginfo` structure (see `<sys/siginfo.h>`). If the specified signal number is zero, the current signal is cleared. The semantics of this operation are different from those of `kill(2)` in that the signal is delivered to the lwp immediately after execution is resumed (even if it is being blocked) and an additional `PR_SIGNALED` stop does not intervene even if the signal is traced. Setting the current signal to `SIGKILL` terminates the process immediately.

proc(4)

PCKILL	If applied to the process control file, a signal is sent to the process with semantics identical to those of <code>kill(2)</code> . If applied to an lwp control file, a directed signal is sent to the specific lwp. The signal is named in a <code>long</code> operand contained in the message. Sending <code>SIGKILL</code> terminates the process immediately.																								
PCUNKILL	A signal is deleted, that is, it is removed from the set of pending signals. If applied to the process control file, the signal is deleted from the process's pending signals. If applied to an lwp control file, the signal is deleted from the lwp's pending signals. The current signal (if any) is unaffected. The signal is named in a <code>long</code> operand in the control message. It is an error (<code>EINVAL</code>) to attempt to delete <code>SIGKILL</code> .																								
PCSHOLD	Set the set of held signals for the specific or representative lwp (signals whose delivery will be blocked if sent to the lwp). The set of signals is specified with a <code>sigset_t</code> operand. <code>SIGKILL</code> and <code>SIGSTOP</code> cannot be held; if specified, they are silently ignored.																								
PCSFAULT	Define a set of hardware faults to be traced in the process. On incurring one of these faults, an lwp stops. The set is defined via the operand <code>fltset_t</code> structure. Fault names are defined in <code><sys/fault.h></code> and include the following. Some of these may not occur on all processors; there may be processor-specific faults in addition to these. <table><tr><td><code>FLTILL</code></td><td>illegal instruction</td></tr><tr><td><code>FLTPRIV</code></td><td>privileged instruction</td></tr><tr><td><code>FLTBPT</code></td><td>breakpoint trap</td></tr><tr><td><code>FLTTRACE</code></td><td>trace trap (single-step)</td></tr><tr><td><code>FLTWATCH</code></td><td>watchpoint trap</td></tr><tr><td><code>FLTACCESS</code></td><td>memory access fault (bus error)</td></tr><tr><td><code>FLTBOUNDS</code></td><td>memory bounds violation</td></tr><tr><td><code>FLTIOVF</code></td><td>integer overflow</td></tr><tr><td><code>FLTIZDIV</code></td><td>integer zero divide</td></tr><tr><td><code>FLTFPE</code></td><td>floating-point exception</td></tr><tr><td><code>FLTSTACK</code></td><td>unrecoverable stack fault</td></tr><tr><td><code>FLTPAGE</code></td><td>recoverable page fault</td></tr></table> When not traced, a fault normally results in the posting of a signal to the lwp that incurred the fault. If an lwp stops on a fault, the signal is posted to the lwp when execution is resumed unless the fault is cleared by <code>PCCFAULT</code> or by the <code>PRCFAULT</code> option of <code>PCRUN</code> . <code>FLTPAGE</code> is an exception; no signal is posted. The <code>pr_info</code> field in the <code>lwpstatus</code> structure identifies the signal to be sent and contains machine-specific information about the fault.	<code>FLTILL</code>	illegal instruction	<code>FLTPRIV</code>	privileged instruction	<code>FLTBPT</code>	breakpoint trap	<code>FLTTRACE</code>	trace trap (single-step)	<code>FLTWATCH</code>	watchpoint trap	<code>FLTACCESS</code>	memory access fault (bus error)	<code>FLTBOUNDS</code>	memory bounds violation	<code>FLTIOVF</code>	integer overflow	<code>FLTIZDIV</code>	integer zero divide	<code>FLTFPE</code>	floating-point exception	<code>FLTSTACK</code>	unrecoverable stack fault	<code>FLTPAGE</code>	recoverable page fault
<code>FLTILL</code>	illegal instruction																								
<code>FLTPRIV</code>	privileged instruction																								
<code>FLTBPT</code>	breakpoint trap																								
<code>FLTTRACE</code>	trace trap (single-step)																								
<code>FLTWATCH</code>	watchpoint trap																								
<code>FLTACCESS</code>	memory access fault (bus error)																								
<code>FLTBOUNDS</code>	memory bounds violation																								
<code>FLTIOVF</code>	integer overflow																								
<code>FLTIZDIV</code>	integer zero divide																								
<code>FLTFPE</code>	floating-point exception																								
<code>FLTSTACK</code>	unrecoverable stack fault																								
<code>FLTPAGE</code>	recoverable page fault																								
PCCFAULT	The current fault, if any, is cleared; the associated signal will not be sent to the specific or representative lwp.																								

**PCSENTRY
PCSEXIT**

These control operations instruct the process's lwps to stop on entry to or exit from specified system calls. The set of system calls to be traced is defined via an operand `sysset_t` structure.

When entry to a system call is being traced, an lwp stops after having begun the call to the system but before the system call arguments have been fetched from the lwp. When exit from a system call is being traced, an lwp stops on completion of the system call just prior to checking for signals and returning to user level. At this point, all return values have been stored into the lwp's registers.

If an lwp is stopped on entry to a system call (`PR_SYSENTRY`) or when sleeping in an interruptible system call (`PR_ASLEEP` is set), it may be instructed to go directly to system call exit by specifying the `PR_SABORT` flag in a `PCRUN` control message. Unless exit from the system call is being traced, the lwp returns to user level showing `EINTR`.

PCWATCH

Set or clear a watched area in the controlled process from a `prwatch` structure operand:

```
typedef struct prwatch {
    uintptr_t pr_vaddr; /* virtual address of watched area */
    size_t pr_size; /* size of watched area in bytes */
    int pr_wflags; /* watch type flags */
} prwatch_t;
```

`pr_vaddr` specifies the virtual address of an area of memory to be watched in the controlled process. `pr_size` specifies the size of the area, in bytes. `pr_wflags` specifies the type of memory access to be monitored as a bit-mask of the following flags:

<code>WA_READ</code>	read access
<code>WA_WRITE</code>	write access
<code>WA_EXEC</code>	execution access
<code>WA_TRAPAFTER</code>	trap after the instruction completes

If `pr_wflags` is non-empty, a watched area is established for the virtual address range specified by `pr_vaddr` and `pr_size`. If `pr_wflags` is empty, any previously-established watched area starting at the specified virtual address is cleared; `pr_size` is ignored.

A watchpoint is triggered when an lwp in the traced process makes a memory reference that covers at least one byte of a watched area and the memory reference is as specified in `pr_wflags`. When an lwp triggers a watchpoint, it incurs a watchpoint trap. If `FLTWATCH` is being traced, the lwp stops; otherwise, it is sent a `SIGTRAP` signal; if `SIGTRAP` is being traced and is not blocked, the lwp stops.

The watchpoint trap occurs before the instruction completes unless `WA_TRAPAFTER` was specified, in which case it occurs after the instruction completes. If it occurs before completion, the memory is not modified. If it occurs after completion, the memory is modified (if the access is a write access).

proc(4)

`pr_info` in the `lwpstatus` structure contains information pertinent to the watchpoint trap. In particular, the `si_addr` field contains the virtual address of the memory reference that triggered the watchpoint, and the `si_code` field contains one of `TRAP_RWATCH`, `TRAP_WWATCH`, or `TRAP_XWATCH`, indicating read, write, or execute access, respectively. The `si_trapafter` field is zero unless `WA_TRAPAFTER` is in effect for this watched area; non-zero indicates that the current instruction is not the instruction that incurred the watchpoint trap. The `si_pc` field contains the virtual address of the instruction that incurred the trap.

A watchpoint trap may be triggered while executing a system call that makes reference to the traced process's memory. The `lwp` that is executing the system call incurs the watchpoint trap while still in the system call. If it stops as a result, the `lwpstatus` structure contains the system call number and its arguments. If the `lwp` does not stop, or if it is set running again without clearing the signal or fault, the system call fails with `EFAULT`. If `WA_TRAPAFTER` was specified, the memory reference will have completed and the memory will have been modified (if the access was a write access) when the watchpoint trap occurs.

If more than one of `WA_READ`, `WA_WRITE`, and `WA_EXEC` is specified for a watched area, and a single instruction incurs more than one of the specified types, only one is reported when the watchpoint trap occurs. The precedence is `WA_EXEC`, `WA_READ`, `WA_WRITE` (`WA_EXEC` and `WA_READ` take precedence over `WA_WRITE`), unless `WA_TRAPAFTER` was specified, in which case it is `WA_WRITE`, `WA_READ`, `WA_EXEC` (`WA_WRITE` takes precedence).

`PCWATCH` fails with `EINVAL` if an attempt is made to specify overlapping watched areas or if `pr_wflags` contains flags other than those specified above. It fails with `ENOMEM` if an attempt is made to establish more watched areas than the system can support (the system can support thousands).

The child of a `vfork(2)` borrows the parent's address space. When a `vfork(2)` is executed by a traced process, all watched areas established for the parent are suspended until the child terminates or performs an `exec(2)`. Any watched areas established independently in the child are cancelled when the parent resumes after the child's termination or `exec(2)`. `PCWATCH` fails with `EBUSY` if applied to the parent of a `vfork(2)` before the child has terminated or performed an `exec(2)`. The `PR_VFORKP` flag is set in the `pstatus` structure for such a parent process.

Certain accesses of the traced process's address space by the operating system are immune to watchpoints. The initial construction of a signal stack frame when a signal is delivered to an `lwp` will not trigger a watchpoint trap even if the new frame covers watched areas of the stack. Once the signal handler is entered, watchpoint traps occur normally. On SPARC based machines, register window overflow and underflow will not trigger watchpoint traps, even if the register window save areas cover watched areas of the stack.

PCSET PCUNSET

Watched areas are not inherited by child processes, even if the traced process's inherit-on-fork mode, `PR_FORK`, is set (see `PCSET`, below). All watched areas are cancelled when the traced process performs a successful `exec(2)`.

`PCSET` sets one or more modes of operation for the traced process. `PCUNSET` unsets these modes. The modes to be set or unset are specified by flags in an operand `long` in the control message:

<code>PR_FORK</code>	(inherit-on-fork): When set, the process's tracing flags and its inherit-on-fork mode are inherited by the child of a <code>fork(2)</code> , <code>fork1(2)</code> , or <code>vfork(2)</code> . When unset, child processes start with all tracing flags cleared.
<code>PR_RLC</code>	(run-on-last-close): When set and the last writable <code>/proc</code> file descriptor referring to the traced process or any of its lwps is closed, all of the process's tracing flags and watched areas are cleared, any outstanding stop directives are canceled, and if any lwps are stopped on events of interest, they are set running as though <code>PCRUN</code> had been applied to them. When unset, the process's tracing flags and watched areas are retained and lwps are not set running on last close.
<code>PR_KLC</code>	(kill-on-last-close): When set and the last writable <code>/proc</code> file descriptor referring to the traced process or any of its lwps is closed, the process is terminated with <code>SIGKILL</code> .
<code>PR_ASYNC</code>	(asynchronous-stop): When set, a stop on an event of interest by one lwp does not directly affect any other lwp in the process. When unset and an lwp stops on an event of interest other than <code>PR_REQUESTED</code> , all other lwps in the process are directed to stop.
<code>PR_MSACCT</code>	(microstate accounting): When set, microstate accounting is enabled for the process. This allows the <code>usage</code> file to contain accurate values for the times the lwps spent in their various processing states. When unset (the default), the overhead of microstate accounting is avoided and the <code>usage</code> file can only contain an estimate of times spent in the various states.
<code>PR_MSFOK</code>	(inherit microstate accounting): When set, and microstate accounting is enabled for the process, microstate accounting will be enabled for future child processes. When unset, child processes start with microstate accounting disabled.
<code>PR_BPTADJ</code>	(breakpoint trap pc adjustment): On IA based machines, a breakpoint trap leaves the program counter (the EIP) referring to the breakpointed instruction plus one byte. When <code>PR_BPTADJ</code> is set, the system will adjust the program counter back to the location of the breakpointed instruction when the lwp stops on a breakpoint. This flag has no effect on SPARC based machines,

proc(4)

	<p>where breakpoint traps leave the program counter referring to the breakpointed instruction.</p>
PR_PTRACE	<p>(ptrace-compatibility): When set, a stop on an event of interest by the traced process is reported to the parent of the traced process via <code>wait(2)</code>, <code>SIGTRAP</code> is sent to the traced process when it executes a successful <code>exec(2)</code>, <code>setuid/setgid</code> flags are not honored for execs performed by the traced process, any <code>exec</code> of an object file that the traced process cannot read fails, and the process dies when its parent dies. This mode is deprecated; it is provided only to allow <code>ptrace(2)</code> to be implemented as a library function using <code>/proc</code>.</p>
	<p>It is an error (<code>EINVAL</code>) to specify flags other than those described above or to apply these operations to a system process. The current modes are reported in the <code>pr_flags</code> field of <code>/proc/pid/status</code> and <code>/proc/pid/lwp/lwp/lwpstatus</code>.</p>
PCSREG	<p>Set the general registers for the specific or representative lwp according to the operand <code>prgreset_t</code> structure.</p> <p>On SPARC based systems, only the condition-code bits of the processor-status register (<code>R_PSR</code>) of SPARC V8 (32-bit) processes can be modified by <code>PCSREG</code>. Other privileged registers cannot be modified at all.</p> <p>On IA based systems, only certain bits of the flags register (<code>EFL</code>) can be modified by <code>PCSREG</code>: these include the condition codes, direction-bit, and overflow-bit.</p> <p><code>PCSREG</code> fails with <code>EBUSY</code> if the lwp is not stopped on an event of interest.</p>
PCSVADDR	<p>Set the address at which execution will resume for the specific or representative lwp from the operand <code>long</code>. On SPARC based systems, both <code>%pc</code> and <code>%npc</code> are set, with <code>%npc</code> set to the instruction following the virtual address. On IA based systems, only <code>%eip</code> is set. <code>PCSVADDR</code> fails with <code>EBUSY</code> if the lwp is not stopped on an event of interest.</p>
PCSFPREG	<p>Set the floating-point registers for the specific or representative lwp according to the operand <code>prfpreset_t</code> structure. An error (<code>EINVAL</code>) is returned if the system does not support floating-point operations (no floating-point hardware and the system does not emulate floating-point machine instructions). <code>PCSFPREG</code> fails with <code>EBUSY</code> if the lwp is not stopped on an event of interest.</p>
PCSXREG	<p>Set the extra state registers for the specific or representative lwp according to the architecture-dependent operand <code>prxreset_t</code> structure. An error (<code>EINVAL</code>) is returned if the system does not support extra state registers. <code>PCSXREG</code> fails with <code>EBUSY</code> if the lwp is not stopped on an event of interest.</p>
PCSASRS	<p>Set the ancillary state registers for the specific or representative lwp according to the SPARC V9 platform-dependent operand <code>asrset_t</code> structure. An error (<code>EINVAL</code>) is returned if either the target process or the controlling process is not a 64-bit SPARC V9</p>

process. Most of the ancillary state registers are privileged registers that cannot be modified. Only those that can be modified are set; all others are silently ignored. PCSASRS fails with EBUSY if the lwp is not stopped on an event of interest.

PCAGENT Create an agent lwp in the controlled process with register values from the operand `prgregset_t` structure (see PCSREG, above). The agent lwp is created in the stopped state showing PR_REQUESTED and with its held signal set (the signal mask) having all signals except SIGKILL and SIGSTOP blocked.

The PCAGENT operation fails with EBUSY unless the process is fully stopped via `/proc`, that is, unless all of the lwps in the process are stopped either on events of interest or on PR_SUSPENDED, or are stopped on PR_JOBCONTROL and have been directed to stop via PCDSTOP. It fails with EBUSY if an agent lwp already exists. It fails with ENOMEM if system resources for creating new lwps have been exhausted.

Any PCRUN operation applied to the process control file or to the control file of an lwp other than the agent lwp fails with EBUSY as long as the agent lwp exists. The agent lwp must be caused to terminate by executing the `_lwp_exit(2)` system call before the process can be restarted.

Once the agent lwp is created, its lwp-ID can be found by reading the process status file. To facilitate opening the agent lwp's control and status files, the directory name `/proc/pid/lwp/agent` is accepted for lookup operations as an invisible alias for `/proc/pid/lwp/lwpid`, `lwpid` being the lwp-ID of the agent lwp (invisible in the sense that the name "agent" does not appear in a directory listing of `/proc/pid/lwp` obtained from `ls(1)`, `getdents(2)`, or `readdir(3C)`).

The purpose of the agent lwp is to perform operations in the controlled process on behalf of the controlling process: to gather information not directly available via `/proc` files, or in general to make the process change state in ways not directly available via `/proc` control operations. To make use of an agent lwp, the controlling process must be capable of making it execute system calls (specifically, the `_lwp_exit(2)` system call). The register values given to the agent lwp on creation are typically the registers of the representative lwp, so that the agent lwp can use its stack.

The agent lwp is not allowed to execute any variation of the `fork(2)`, `exec(2)`, or `_lwp_create(2)` system calls. Attempts to do so yield ENOTSUP to the agent lwp.

PCREAD
PCWRITE Read or write the target process's address space via a `priovec` structure operand:

```
typedef struct priovec {
    void *pio_base;      /* buffer in controlling process */
    size_t pio_len;     /* size of read/write request in bytes */
    off_t pio_offset;   /* virtual address in target process */
} priovec_t;
```

These operations have the same effect as `pread(2)` and `pwrite(2)`, respectively, of the target process's address space file. The difference is that more than one PCREAD or PCWRITE control operation can be written to the control file at once, and they can be interspersed with other control operations in a single write to the control file. This is

proc(4)

useful, for example, when planting many breakpoint instructions in the process's address space, or when stepping over a breakpointed instruction. Unlike `pread(2)` and `pwrite(2)`, no provision is made for partial reads or writes; if the operation cannot be performed completely, it fails with `EIO`.

PCNICE The traced process's `nice(2)` value is incremented by the amount in the operand `long`. Only the super-user may better a process's priority in this way, but any user may lower the priority. This operation is not meaningful for all scheduling classes.

PCSCRED Set the target process credentials to the values contained in the `prcred_t` structure operand (see `/proc/pid/cred`). The effective, real, and saved user-IDs and group-IDs of the target process are set. The target process's supplementary groups are not changed; the `pr_ngroups` and `pr_groups` members of the structure operand are ignored. Only the super-user may perform this operation; for all others it fails with `EPERM`.

PROGRAMMING NOTES

For security reasons, except for the `psinfo`, `usage`, `lpsinfo`, `lusage`, `lwpsinfo`, and `lwpusage` files, which are world-readable, and except for the super-user, an open of a `/proc` file fails unless both the user-ID and group-ID of the caller match those of the traced process and the process's object file is readable by the caller. Except for the world-readable files just mentioned, files corresponding to `setuid` and `setgid` processes can be opened only by the super-user.

Even if held by the super-user, an open process or lwp file descriptor (other than file descriptors for the world-readable files) becomes invalid if the traced process performs an `exec(2)` of a `setuid/setgid` object file or an object file that the traced process cannot read. Any operation performed on an invalid file descriptor, except `close(2)`, fails with `EAGAIN`. In this situation, if any tracing flags are set and the process or any lwp file descriptor is open for writing, the process will have been directed to stop and its run-on-last-close flag will have been set (see `PCSET`). This enables a controlling process (if it has permission) to reopen the `/proc` files to get new valid file descriptors, close the invalid file descriptors, unset the run-on-last-close flag (if desired), and proceed. Just closing the invalid file descriptors causes the traced process to resume execution with all tracing flags cleared. Any process not currently open for writing via `/proc`, but that has left-over tracing flags from a previous open, and that executes a `setuid/setgid` or unreadable object file, will not be stopped but will have all its tracing flags cleared.

To wait for one or more of a set of processes or lwps to stop or terminate, `/proc` file descriptors (other than those obtained by opening the `cwd` or `root` directories or by opening files in the `fd` or `object` directories) can be used in a `poll(2)` system call. When requested and returned, either of the polling events `POLLPRI` or `POLLWRNORM` indicates that the process or lwp stopped on an event of interest. Although they cannot be requested, the polling events `POLLHUP`, `POLLERR`, and `POLLNVAL` may be returned. `POLLHUP` indicates that the process or lwp has terminated. `POLLERR` indicates that the file descriptor has become invalid. `POLLNVAL` is returned

immediately if `POLLPRI` or `POLLWRNORM` is requested on a file descriptor referring to a system process (see `PCSTOP`). The requested events may be empty to wait simply for termination.

FILES

- `/proc`
directory (list of processes)
- `/proc/pid`
specific process directory
- `/proc/self`
alias for a process's own directory
- `/proc/pid/as`
address space file
- `/proc/pid/ctl`
process control file
- `/proc/pid/status`
process status
- `/proc/pid/lstatus`
array of lwp status structs
- `/proc/pid/psinfo`
process `ps(1)` info
- `/proc/pid/lpsinfo`
array of lwp `ps(1)` info structs
- `/proc/pid/map`
address space map
- `/proc/pid/rmap`
reserved address map
- `/proc/pid/cred`
process credentials
- `/proc/pid/sigact`
process signal actions
- `/proc/pid/auxv`
process aux vector
- `/proc/pid/ldt`
process LDT (IA only)
- `/proc/pid/usage`
process usage
- `/proc/pid/lusage`
array of lwp usage structs

DIAGNOSTICS Errors that can occur in addition to the errors normally associated with file system access:

ENOENT	The traced process or lwp has terminated after being opened.
EIO	A write(2) was attempted at an illegal address in the traced process.
EBUSY	PCSTOP, PCDSTOP, PCWSTOP, or PCTWSTOP was applied to a system process; an exclusive open(2) was attempted on a /proc file for a process already open for writing; PCRUN, PCSREG, PCSVADDR, PCSFPREG, or PCSXREG was applied to a process or lwp not stopped on an event of interest; an attempt was made to mount /proc when it was already mounted; PCAGENT was applied to a process that was not fully stopped or that already had an agent lwp.
EPERM	Someone other than the super-user issued the PCSCRED operation; someone other than the super-user attempted to better a process's priority by applying PCNICE.
ENOSYS	An attempt was made to perform an unsupported operation (such as creat(2), link(2), or unlink(2)) on an entry in /proc.
EINVAL	In general, this means that some invalid argument was supplied to a system call. A non-exhaustive list of conditions eliciting this error includes: a control message operation code is undefined; an out-of-range signal number was specified with PCSSIG, PCKILL, or PCUNKILL; SIGKILL was specified with PCUNKILL; PCSFPREG was applied on a system that does not support floating-point operations; PCSXREG was applied on a system that does not support extra state registers.
ENOMEM	The system-imposed limit on the number of page data file descriptors was reached on an open of /proc/pid/pagedata; an attempt was made with PCWATCH to establish more watched areas than the system can support; the PCAGENT operation was issued when the system was out of resources for creating lwps.
E2BIG	Data to be returned in a read(2) of the page data file exceeds the size of the read buffer provided by the caller.

proc(4)

EINTR	A signal was received by the controlling process while waiting for the traced process or lwp to stop via PCSTOP, PCWSTOP, or PCTWSTOP.
EAGAIN	The traced process has performed an exec(2) of a setuid/setgid object file or of an object file that it cannot read; all further operations on the process or lwp file descriptor (except close(2)) elicit this error.
E_OVERFLOW	A 32-bit controlling process attempted to read or write the as file or attempted to read the map, rmap, or pagedata file of a 64-bit target process. A 32-bit controlling process attempted to apply one of the control operations PCSREG, PCSXREG, PCSVADDR, PCWATCH, PCAGENT, PCREAD, PCWRITE to a 64-bit target process.

NOTES Descriptions of structures in this document include only interesting structure elements, not filler and padding fields, and may show elements out of order for descriptive clarity. The actual structure definitions are contained in `<procfs.h>`.

BUGS Because the old `ioctl(2)`-based version of `/proc` is currently supported for binary compatibility with old applications, the top-level directory for a process, `/proc/pid`, is not world-readable, but it is world-searchable. Thus, anyone can open `/proc/pid/psinfo` even though `ls(1)` applied to `/proc/pid` will fail for anyone but the owner or the super-user. Support for the old `ioctl(2)`-based version of `/proc` will be dropped in a future release, at which time the top-level directory for a process will be made world-readable.

On SPARC based machines, the types `gregset_t` and `fpregset_t` defined in `<sys/regset.h>` are similar to but not the same as the types `prgregset_t` and `prfpregset_t` defined in `<procfs.h>`.

NAME	prof_attr – profile description database
SYNOPSIS	/etc/security/prof_attr
DESCRIPTION	<p>/etc/security/prof_attr is a local source for execution profile names, descriptions, and other attributes of execution profiles. The prof_attr file can be used with other profile sources, including the prof_attr NIS map and NIS+ table. Programs use the getprofattr(3SECDB) routines to gain access to this information.</p> <p>The search order for multiple prof_attr sources is specified in the /etc/nsswitch.conf file, as described in the nsswitch.conf(4) man page.</p> <p>An execution profile is a mechanism used to bundle together the commands and authorizations needed to perform a specific function. An execution profile can also contain other execution profiles. Each entry in the prof_attr database consists of one line of text containing five fields separated by colons (:). Line continuations using the backslash (\) character are permitted. The format of each entry is:</p> <pre>profname:res1:res2:desc:attr</pre> <p><i>profname</i> The name of the profile. Profile names are case-sensitive.</p> <p><i>res1</i> Reserved for future use.</p> <p><i>res2</i> Reserved for future use.</p> <p><i>desc</i> A long description. This field should explain the purpose of the profile, including what type of user would be interested in using it. The long description should be suitable for displaying in the help text of an application.</p> <p><i>attr</i> An optional list of semicolon-separated (;) key-value pairs that describe the security attributes to apply to the object upon execution. Zero or more keys may be specified. There are three valid keys: help, profs, and auths.</p> <p> help is assigned the name of a file ending in .htm or .html.</p> <p> auths specifies a comma-separated list of authorization names chosen from those names defined in the auth_attr(4) database. Authorization names may be specified using the asterisk (*) character as a wildcard. For example, solaris.printer.* would mean all of Sun's authorizations for printing.</p> <p> profs specifies a comma-separated list of profile names chosen from those names defined in the prof_attr database.</p>

prof_attr(4)

EXAMPLES

EXAMPLE 1 Allowing execution of all commands

The following entry allows the user to execute all commands:

```
All:::Use this profile to give a :help=All.html
```

EXAMPLE 2 Consulting the local prof_attr file first

With the following nsswitch.conf entry, the local prof_attr file is consulted before the NIS+ table:

```
prof_attr: files nisplus
```

FILES

/etc/nsswitch.conf

/etc/security/prof_attr

NOTES

When deciding which authorization source to use (see DESCRIPTION), keep in mind that NIS+ provides stronger authentication than NIS.

The root user is usually defined in local databases because root needs to be able to log in and do system maintenance in single-user mode and at other times when the network name service databases are not available. So that the profile definitions for root can be located at such times, root's profiles should be defined in the local prof_attr file, and the order shown in the example nsswitch.conf(4) file entry under EXAMPLES is highly recommended.

Because the list of legal keys is likely to expand, any code that parses this database must be written to ignore unknown key-value pairs without error. When any new keywords are created, the names should be prefixed with a unique string, such as the company's stock symbol, to avoid potential naming conflicts.

Each application has its own requirements for whether the help value must be a relative pathname ending with a filename or the name of a file. The only known requirement is for the name of a file.

The following characters are used in describing the database format and must be escaped with a backslash if used as data: colon (:), semicolon (;), equals (=), and backslash (\).

NAME	profile – setting up an environment for user at login time
SYNOPSIS	<pre>/etc/profile \$HOME/.profile</pre>
DESCRIPTION	<p>All users who have the shell, <code>sh(1)</code>, as their login command have the commands in these files executed as part of their login sequence.</p> <p><code>/etc/profile</code> allows the system administrator to perform services for the entire user community. Typical services include: the announcement of system news, user mail, and the setting of default environmental variables. It is not unusual for <code>/etc/profile</code> to execute special actions for the <code>root</code> login or the <code>su</code> command.</p> <p>The file <code>\$HOME/.profile</code> is used for setting per-user exported environment variables and terminal modes. The following example is typical (except for the comments):</p> <pre># Make some environment variables global export MAIL PATH TERM # Set file creation mask umask 022 # Tell me when new mail comes in MAIL=/var/mail/\$LOGNAME # Add my /usr/usr/bin directory to the shell search sequence PATH=\$PATH:\$HOME/bin # Set terminal type TERM=\${L0:-u/n/k/n/o/w/n} # gnar.invalid while : do if [-f \${TERMINFO:-/usr/share/lib/terminfo}/?/\$TERM] then break elif [-f /usr/share/lib/terminfo/?/\$TERM] then break else echo "invalid term \$TERM" 1>&2 fi echo "terminal: \c" read TERM done # Initialize the terminal and set tabs # Set the erase character to backspace stty erase '^H' echoe</pre>
FILES	<pre>\$HOME/.profile user-specific environment /etc/profile system-wide environment</pre>
SEE ALSO	<pre>env(1), login(1), mail(1), sh(1), stty(1), tput(1), su(1M), terminfo(4), environ(5), term(5)</pre> <p><i>Solaris Advanced User's Guide</i></p>
NOTES	<p>Care must be taken in providing system-wide services in <code>/etc/profile</code>. Personal <code>.profile</code> files are better for serving all but the most global needs.</p>

project(4)

NAME	project – project file												
DESCRIPTION	<p>The <code>project</code> file is a local source of project information. The <code>project</code> file can be used in conjunction with other project sources, including the NIS maps <code>project.byname</code> and <code>project.bynumber</code> and the LDAP database <code>project</code>. Programs use the <code>getproject(3PROJECT)</code> routines to access this information.</p> <p>The <code>project</code> file contains a one-line entry for each project recognized by the system, of the form:</p> <pre><i>projname</i> : <i>projid</i> : <i>comment</i> : <i>user-list</i> : <i>group-list</i> : <i>attributes</i></pre> <p>where the fields are defined as:</p> <table><tr><td><i>projname</i></td><td>The name of the project. Allowable project names must begin with a letter, and may be composed of any letter or digit and the underscore character. The period (‘.’) is reserved for projects with special meaning to the operating system.</td></tr><tr><td><i>projid</i></td><td>The project’s unique numerical ID (PROJID) within the system.</td></tr><tr><td><i>comment</i></td><td>The project’s description.</td></tr><tr><td><i>user-list</i></td><td>A comma-separated list of users allowed in the project.</td></tr><tr><td><i>group-list</i></td><td>A comma-separated list of groups of users allowed in the project.</td></tr><tr><td><i>attributes</i></td><td>A semicolon-separated list of name value pairs. Each pair has the following format:</td></tr></table> <pre><i>name</i>[=<i>value</i>]</pre> <p>where <i>name</i> is the arbitrary string specifying the key’s name and <i>value</i> is the optional key value. An explanation of the valid name-value pair syntax is provided in the <code>USAGE</code> section of this page. The expected most frequent use of the attribute field is for the specification of resource controls.</p> <p>The maximum value of the <i>projid</i> field is <code>MAXPROJID</code>.</p> <p>Malformed entries cause routines that read this file to halt, in which case project assignments specified further along are never made. Blank lines are treated as malformed entries in the <code>project</code> file, and will cause <code>getproject(3PROJECT)</code> and derived interfaces to fail.</p>	<i>projname</i>	The name of the project. Allowable project names must begin with a letter, and may be composed of any letter or digit and the underscore character. The period (‘.’) is reserved for projects with special meaning to the operating system.	<i>projid</i>	The project’s unique numerical ID (PROJID) within the system.	<i>comment</i>	The project’s description.	<i>user-list</i>	A comma-separated list of users allowed in the project.	<i>group-list</i>	A comma-separated list of groups of users allowed in the project.	<i>attributes</i>	A semicolon-separated list of name value pairs. Each pair has the following format:
<i>projname</i>	The name of the project. Allowable project names must begin with a letter, and may be composed of any letter or digit and the underscore character. The period (‘.’) is reserved for projects with special meaning to the operating system.												
<i>projid</i>	The project’s unique numerical ID (PROJID) within the system.												
<i>comment</i>	The project’s description.												
<i>user-list</i>	A comma-separated list of users allowed in the project.												
<i>group-list</i>	A comma-separated list of groups of users allowed in the project.												
<i>attributes</i>	A semicolon-separated list of name value pairs. Each pair has the following format:												
EXAMPLES	<p>EXAMPLE 1 Sample project File</p> <p>The following is a sample <code>project</code> file:</p> <pre>system:0:System::: user.root:1:Super-User::: noproject:2:No Project::: default:3::::</pre>												

EXAMPLE 1 Sample project File (Continued)

```
group.staff:10:::
beatles:100:The Beatles:john,paul,george,ringo::task.max-lwps=
    (privileged,100,signal=SIGTERM), (privileged,110,deny)
```

Note that the line break in the line that begins with `beatles` is not valid in a project file. It is shown here only to allow the example to display on a printed or displayed page. Each entry must be on one and only one line.

An example project entry for `nsswitch.conf(4)` is:

```
project: files nis
```

With these entries, the project `beatles` will have members `john`, `paul`, `george`, and `ringo`, and all projects listed in the NIS project table are effectively incorporated after the entry for `beatles`.

The `beatles` project has two values set on the `task.max-lwps` resource control. When a task in the `beatles` project requests (via one of its member processes) its 100th and 110th LWPs, an action associated with the encountered threshold triggers. Upon the request for the 100th LWP, the process making the request is sent the signal `SIGTERM` and is granted the request for an additional lightweight process (LWP). At this point, the threshold for 110 LWPs becomes the active threshold. When a request for the 110th LWP in the task is made, the requesting process is denied the request—no LWP will be created. Since the 110th LWP is never granted, the threshold remains active, and all subsequent requests for an 110th LWP will fail. (If LWPs are given up, then subsequent requests will succeed, unless they would take the total number of LWPs across the task over 110.)

USAGE The project database offers a reasonably flexible attribute mechanism in the final name-value pair field. Name-value pairs are separated from one another with the semicolon (;) character. The name is in turn distinguished from the (optional) value by the equals (=) character. The value field can contain multiple values separated by the comma (,) character, with grouping support (into further values lists) by parentheses. Each of these values can be composed of the upper and lower case alphabetic characters, the digits '0' through '9', and the punctuation characters hyphen (-), plus (+), period (.), slash (/), and underscore (_). Example resource control value specifications are provided in **EXAMPLES**, above, and on the `getproject(3PROJECT)` manual page.

protocols(4)

NAME	protocols – protocol name database
SYNOPSIS	<pre>/etc/inet/protocols /etc/protocols</pre>
DESCRIPTION	<p>The <code>protocols</code> file is a local source of information regarding the known protocols used in the DARPA Internet. The <code>protocols</code> file can be used in conjunction with or instead of other protocols sources, including the NIS maps “<code>protocols.byname</code>” and “<code>protocols.bynumber</code>” and the NIS+ table “<code>protocols</code>”. Programs use the <code>getprotobyname(3SOCKET)</code> routine to access this information.</p> <p>The <code>protocols</code> file has one line for each protocol. The line has the following format:</p> <pre>official-protocol-name protocol-number aliases</pre> <p>Items are separated by any number of blanks and/or TAB characters. A ‘#’ indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file. Protocol names may contain any printable character other than a field delimiter, NEWLINE, or comment character.</p>
EXAMPLES	<p>EXAMPLE 1 A Sample Database</p> <p>The following is a sample database:</p> <pre># # Internet (IP) protocols # ip 0 IP # internet protocol, pseudo protocol number icmp 1 ICMP # internet control message protocol ggp 3 GGP # gateway-gateway protocol tcp 6 TCP # transmission control protocol egp 8 EGP # exterior gateway protocol pup 12 PUP # PARC universal packet protocol udp 17 UDP # user datagram protocol # # Internet (IPv6) extension headers # hopopt 0 HOPOPT # Hop-by-hop options for IPv6 ipv6 41 IPv6 # IPv6 in IP encapsulation ipv6-route 43 IPv6-Route # Routing header for IPv6 ipv6-frag 44 IPv6-Frag # Fragment header for IPv6 esp 50 ESP # Encap Security Payload for IPv6 ah 51 AH # Authentication Header for IPv6 ipv6-icmp 58 IPv6-ICMP # IPv6 internet control message protocol ipv6-nonxt 59 IPv6-NoNxt # No next header extension header for IPv6 ipv6-opts 60 IPv6-Opts # Destination Options for IPv6</pre>
FILES	<pre>/etc/nsswitch.conf</pre> configuration file for name-service switch
SEE ALSO	<code>getprotobyname(3SOCKET)</code> , <code>nsswitch.conf(4)</code>

NOTES | `/etc/inet/protocols` is the official SVR4 name of the `protocols` file. The symbolic link `/etc/protocols` exists for BSD compatibility.

prototype(4)

NAME	prototype – package information file
DESCRIPTION	<p>prototype is an ASCII file used to specify package information. Each entry in the file describes a single deliverable object. An object may be a data file, directory, source file, executable object, and so forth. This file is generated by the package developer.</p> <p>Entries in a <code>prototype</code> file consist of several fields of information separated by white space. Comment lines begin with a “#” and are ignored. The fields are described below and must appear in the order shown.</p> <p><i>part</i> An optional field designating the part number in which the object resides. A part is a collection of files and is the atomic unit by which a package is processed. A developer can choose criteria for grouping files into a part (for example, based on class). If this field is not used, part 1 is assumed.</p> <p><i>ftype</i> A one-character field that indicates the file type. Valid values are:</p> <ul style="list-style-type: none">b block special devicec character special deviced directorye a file to be edited upon installation or removal (may be shared by several packages)f a standard executable or data filei installation script or information filel linked filep named pipes symbolic linkv volatile file (one whose contents are expected to change, like a log file)x an exclusive directory accessible only by this package <p><i>class</i> The installation class to which the file belongs. This name must contain only alphanumeric characters and be no longer than 12 characters. The field is not specified for installation scripts. (<code>admin</code> and all classes beginning with capital letters are reserved class names.)</p> <p><i>pathname</i> The pathname where the file will reside on the target machine, for example, <code>/usr/bin/mail</code> or <code>bin/ras/proc</code>. Relative pathnames (those that do not begin with a slash) indicate that the file is relocatable. The form</p> <p style="text-align: center;"><i>path1=path2</i></p>

may be used for two purposes: to define a link and to define local pathnames.

For linked files, *path1* indicates the destination of the link and *path2* indicates the source file. (This format is mandatory for linked files.)

For local pathnames, *path1* indicates the pathname an object should have on the machine where the entry is to be installed and *path2* indicates either a relative or fixed pathname to a file on the host machine which contains the actual contents.

A pathname may contain a variable specification of the form *\$variable*. If *variable* begins with a lower case letter, it is a build variable. If *variable* begins with an upper case letter, it is an install variable. Build variables are bound at build time. If an install variable is known at build time, its definition is inserted into the `pkginfo(4)` file so that it will be available at install time. If an install variable is not known at build time, it will be bound at install time.

<i>major</i>	The major device number. The field is only specified for block or character special devices.
<i>minor</i>	The minor device number. The field is only specified for block or character special devices.
<i>mode</i>	<p>The octal mode of the file (for example, 0664). A question mark (?) indicates that the mode will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked files or packaging information files.</p> <p>The mode can be a variable specification of the form <i>\$variable</i>. If <i>variable</i> begins with a lower case letter, it is a build variable. If <i>variable</i> begins with an upper case letter, it is an install variable. Build variables are bound at build time. If an install variable is known at build time, its definition is inserted into the <code>pkginfo(4)</code> file so that it will be available at install time. If an install variable is not known at build time, it will be bound at install time.</p>
<i>owner</i>	<p>The owner of the file (for example, <code>bin</code> or <code>root</code>). The field is limited to 14 characters in length. A question mark (?) indicates that the owner will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked files or packaging information files.</p> <p>The owner can be a variable specification of the form <i>\$variable</i>. If <i>variable</i> begins with a lower case letter, it is a build variable. If <i>variable</i> begins with an upper case letter, it is an install variable. Build variables are bound at build time. If an install variable is</p>

prototype(4)

	known at build time, its definition is inserted into the <code>pkginfo(4)</code> file so that it will be available at install time. If an install variable is not known at build time, it will be bound at install time.
<i>group</i>	<p>The group to which the file belongs (for example, <code>bin</code> or <code>sys</code>). The field is limited to 14 characters in length. A question mark (?) indicates that the group will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked files or packaging information files.</p> <p>The group can be a variable specification of the form <code>\$variable</code>. If <i>variable</i> begins with a lower case letter, it is a build variable. If <i>variable</i> begins with an upper case letter, it is an install variable. Build variables are bound at build time. If an install variable is known at build time, its definition is inserted into the <code>pkginfo(4)</code> file so that it will be available at install time. If an install variable is not known at build time, it will be bound at install time.</p>
	<p>An exclamation point (!) at the beginning of a line indicates that the line contains a command. These commands are used to incorporate files in other directories, to locate objects on a host machine, and to set permanent defaults. The following commands are available:</p>
<i>search</i>	Specifies a list of directories (separated by white space) to search for when looking for file contents on the host machine. The base name of the <i>path</i> field is appended to each directory in the ordered list until the file is located. Searches are not recursive.
<i>include</i>	Specifies a pathname which points to another prototype file to include. Note that <i>search</i> requests do not span <i>include</i> files.
<i>default</i>	Specifies a list of attributes (mode, owner, and group) to be used by default if attribute information is not provided for prototype entries which require the information. The defaults do not apply to entries in <i>include</i> prototype files.
<i>param=value</i>	Places the indicated parameter in the current environment. Spans to subsequent included prototype files.

The above commands may have variable substitutions embedded within them, as demonstrated in the two example prototype files below.

Before files are overwritten during installation, they are copied to a temporary pathname. The exception to this rule is files whose mode includes execute permission, unless the file is editable (that is, *f_{type}* is `e`). For files which meet this exception, the existing version is linked to a temporary pathname, and the original file is removed. This allows processes which are executing during installation to be overwritten.

EXAMPLES**EXAMPLE 1** Example 1:

!include $PROJDIR/src/cmd/audmerg/protofile
!include $PROJDIR/src/lib/proto

```

SEE ALSO

pkgmk(1), pkginfo(4)

*Application Packaging Developer's Guide***NOTES**

Normally, if a file is defined in the prototype file but does not exist, that file is created at the time of package installation. However, if the file pathname includes a

prototype(4)

directory that does not exist, the file will not be created. For example, if the `prototype` file has the following entry:

```
f none /usr/dev/bin/command
```

and that file does not exist, it will be created if the directory `/usr/dev/bin` already exists or if the `prototype` also has an entry defining the directory:

```
d none /usr/dev/bin
```

NAME	pseudo – configuration files for pseudo device drivers
DESCRIPTION	<p>Pseudo devices are devices that are implemented entirely in software. Drivers for pseudo devices must provide driver configuration files to inform the system of each pseudo device that should be created.</p> <p>Configuration files for pseudo device drivers must identify the parent driver explicitly as <i>pseudo</i>, and must create an integer property called <i>instance</i> which is unique to this entry in the configuration file.</p> <p>Each entry in the configuration file creates a prototype devinfo node. Each node is assigned an instance number which is determined by the value of the <i>instance</i> property. This property is only applicable to children of the <i>pseudo</i> parent, and is required since pseudo devices have no hardware address from which to determine the instance number. See <code>driver.conf(4)</code> for further details of configuration file syntax.</p>
EXAMPLES	<p>EXAMPLE 1 A sample configuration file.</p> <p>Here is a configuration file called <code>ramdisk.conf</code> for a pseudo device driver that implements a RAM disk. This file creates two nodes called "ramdisk". The first entry creates ramdisk node instance 0, and the second creates ramdisk node, instance 1, with the additional <code>disk-size</code> property set to 512.</p> <pre># # Copyright (c) 1993, by Sun Microsystems, Inc. # #ident "@(#)ramdisk.conf 1.3 93/06/04 SMI" name="ramdisk" parent="pseudo" instance=0; name="ramdisk" parent="pseudo" instance=1 disk-size=512;</pre>
SEE ALSO	<p><code>driver.conf(4)</code>, <code>ddi_prop_op(9F)</code></p> <p><i>Writing Device Drivers</i></p>

publickey(4)

NAME	publickey – public key database
SYNOPSIS	<code>/etc/publickey</code>
DESCRIPTION	<p><code>/etc/publickey</code> is a local public key database that is used for secure RPC. The <code>/etc/publickey</code> file can be used in conjunction with or instead of other publickey databases, including the NIS publickey map and the NIS+ publickey map. Each entry in the database consists of a network user name (which may refer to either a user or a hostname), followed by the user's public key (in hex notation), a colon, and then the user's secret key encrypted with a password (also in hex notation).</p> <p>The <code>/etc/publickey</code> file contains a default entry for nobody.</p>
SEE ALSO	<code>chkey(1)</code> , <code>newkey(1M)</code> , <code>getpublickey(3NSL)</code> , <code>nsswitch.conf(4)</code>

NAME	queuedefs – queue description file for at, batch, and cron
SYNOPSIS	<code>/etc/cron.d/queuedefs</code>
DESCRIPTION	<p>The <code>queuedefs</code> file describes the characteristics of the queues managed by <code>cron(1M)</code>. Each non-comment line in this file describes one queue. The format of the lines are as follows:</p> <pre><i>q</i>. [<i>njobj</i>][<i>nice</i>n][<i>nwait</i>w]</pre> <p>The fields in this line are:</p> <p><i>q</i> The name of the queue. <code>a</code> is the default queue for jobs started by <code>at(1)</code>; <code>b</code> is the default queue for jobs started by <code>batch</code> (see <code>at(1)</code>); <code>c</code> is the default queue for jobs run from a <code>crontab(1)</code> file.</p> <p><i>njob</i> The maximum number of jobs that can be run simultaneously in that queue; if more than <i>njob</i> jobs are ready to run, only the first <i>njob</i> jobs will be run, and the others will be run as jobs that are currently running terminate. The default value is 100.</p> <p><i>nice</i> The <code>nice(1)</code> value to give to all jobs in that queue that are not run with a user ID of super-user. The default value is 2.</p> <p><i>nwait</i> The number of seconds to wait before rescheduling a job that was deferred because more than <i>njob</i> jobs were running in that job's queue, or because the system-wide limit of jobs executing has been reached. The default value is 60.</p> <p>Lines beginning with <code>#</code> are comments, and are ignored.</p>
EXAMPLES	<p>EXAMPLE 1 A sample file.</p> <pre># # a.4j1n b.2j2n90w</pre> <p>This file specifies that the <code>a</code> queue, for <code>at</code> jobs, can have up to 4 jobs running simultaneously; those jobs will be run with a <code>nice</code> value of 1. As no <code>nwait</code> value was given, if a job cannot be run because too many other jobs are running <code>cron</code> will wait 60 seconds before trying again to run it.</p> <p>The <code>b</code> queue, for <code>batch(1)</code> jobs, can have up to 2 jobs running simultaneously; those jobs will be run with a <code>nice(1)</code> value of 2. If a job cannot be run because too many other jobs are running, <code>cron(1M)</code> will wait 90 seconds before trying again to run it. All other queues can have up to 100 jobs running simultaneously; they will be run with a <code>nice</code> value of 2, and if a job cannot be run because too many other jobs are running <code>cron</code> will wait 60 seconds before trying again to run it.</p>

NAME	rcmscript – script interface specification for the Reconfiguration and Coordination Manager
SYNOPSIS	<pre>rcm_scriptname scriptinfo rcm_scriptname register rcm_scriptname resourceinfo resourcename rcm_scriptname queryremove resourcename rcm_scriptname preremove resourcename rcm_scriptname postremove resourcename rcm_scriptname undoremove resourcename</pre>
DESCRIPTION	<p>Reconfiguration and Coordination Manager (RCM) is a framework designed to coordinate device consumers during Solaris Dynamic Reconfiguration (DR). The interfaces specified in this man page allow device consumers, such as application vendors or site administrators, to act before and after DR operations take place by providing RCM scripts. You can write your own RCM scripts to shut down your applications, or to cleanly release the devices from your applications during dynamic remove operations.</p> <p>An RCM script is an executable perl script, a shell script or a binary. Perl is the recommended language. Each script is run in its own address space using the user-id of the script file owner.</p> <p>An RCM script is invoked on demand in response to DR as follows:</p> <pre><scriptname> <command> [args ...]</pre> <p>Every script must implement the following RCM commands:</p> <pre>scriptinfo Get script information. register Register devices the script handles. resourceinfo Get resource information.</pre> <p>A script might include some or all the of the following commands:</p> <pre>queryremove Queries whether the resource can be released. preremove Releases the resource. postremove Provides post-resource removal notification. undoremove Undo the actions done in preremove.</pre> <p>When a script's <code>register</code> command is run, the script should supply, in return data, all resource names the script or its application handles that could potentially be removed by DR. A resource name refers to a name in <code>/dev</code> path name.</p>

rcmscript(4)

Below is a high-level overview of the sequence of script invocations that occurs when dynamic removal of a script's registered resource is attempted. See the COMMANDS section for a detailed description of the commands.

1. Prior to removing the resource from the system during DR, the script's `queryremove` command is run:

```
<scriptname> queryremove <resourcename>
```

The script should check for obvious reasons why the resource can not be removed from the perspective of its service or application.

2. If the script indicates that the resource can be removed in the `queryremove` command. The script's `preremove` command is run:

```
<scriptname> preremove <resourcename>
```

The script releases the resource from the service or application represented by the script and prepares for the resource removal. Releasing the resource includes closing the resource if the resource is currently opened by its application.

3. The system then proceeds to remove the resource.
4. If the system has removed the resource successfully the script's `postremove` command is run:

```
<scriptname> postremove <resourcename>
```

Otherwise the script's `undoremove` command is run:

```
<scriptname> undoremove <resourcename>
```

For any commands the script does not implement, it must exit with exit status of 2. RCM silently returns success for the script's unimplemented commands.

A script performs the following basic steps:

- Takes RCM command and additional arguments from the command line and environment parameters.
- Processes the command.
- Writes the expected return data to stdout as *name=value* pairs delimited by newlines, where *name* is the name of the return data item that RCM expects and *value* is the value associated with the data item.

Environment Initial environment of RCM scripts is set as follows:

- Process UID is set to the UID of the script.
- Process GID is set to the GID of the script.
- PATH variable is set to `/usr/sbin:/usr/bin`.

- Current working directory is set to:
 - /var/run for scripts owned by root
 - /tmp for scripts not owned by root
- File descriptor 0 (stdin) is set to /dev/null
- Environment variable RCM_ENV_DEBUG_LEVEL is set to the debug level. Logging is discussed below.
- The following environment variables are also set where possible:
 - LANG
 - LC_COLLATE
 - LC_CTYPE
 - LC_MESSAGES
 - LC_MONETARY
 - LC_NUMERIC
 - LC_TIME
 - LC_ALL
 - TZ See environ(5) for a description of these variables. See gettext(1) for details on retrieving localized messages.

All environment variable names beginning with RCM_ENV_ are reserved for use by the RCM.

The character encoding used by the RCM and RCM scripts to exchange RCM commands, environment parameters, and name-value pairs is ASCII unless the controlling environment variables are specified otherwise.

Commands `scriptinfo`

The `scriptinfo` command is invoked to gather information about the script.

Return data:

If successful, the script must write the following name-value pairs to stdout and exit with status 0:

- `rcm_script_version=1`
- `rcm_script_func_info=script_func_info`
- `rcm_cmd_timeout=command_timeout_value` where *script_func_info* is a localized human-readable message describing the functionality of the script.

The RCM monitors the execution time of RCM commands by RCM scripts. *command_timeout_value* is the maximum time in seconds the script is expected to take to process any RCM command except the `scriptinfo` command itself. If an RCM script does not process the RCM command and exit within this time, RCM sends a SIGABRT signal to the script process. RCM then waits for a few seconds for the script to finish the processing of the current RCM command and exit. If the script does not exit within this time, RCM sends a SIGKILL signal to the script.

rcmscript(4)

The `rcm_cmd_timeout` name-value pair is optional. It is only needed if the script is expected to take more than a few seconds to process any RCM command. Setting this name to a value of 0 (zero) disables the timer. If this name-value pair is not supplied, a default value is assigned by the RCM.

Upon failure, the script must specify the failure reason using the name-value pair `rcm_failure_reason` and exit with status 1.

`register`

The `register` command is invoked to allow a script to specify the resources that it or its application handles that could potentially be removed by DR. The script has to supply all its resource names to RCM using the name-value pair `rcm_resource_name`.

Return Data:

If successful, the script must write the following name-value pairs to stdout and exit with status 0:

```
rcm_resource_name=resourcename
rcm_resource_name=resourcename
.
.
.
```

where *resourcename* is the name of the resource the script is interested in.

Upon failure, the script must specify the failure reason using the name-value pair `rcm_failure_reason` and exit with status 1.

`resourceinfo resourcename`

The `resourceinfo` command is invoked to get the usage information about *resourcename*.

Return Data:

If successful, the script must write the following name-value pair to stdout and exit with status 0:

```
rcm_resource_usage_info=resource_usage
```

where *resource_usage* is a localized human readable message describing the usage of the resource by the script.

Upon failure, the script must specify the failure reason using the name-value pair `rcm_failure_reason` and exit with status 1.

`queryremove resourcename`

Prior to removing the resource from the system, the `queryremove` command is invoked to query the script to determine whether the script can release the given resource successfully from the service or application it represents. The script does not

actually release the resource. The script might indicate that it is not able to release the resource if the resource is critical for its service or application.

Additional environment parameter:

RCM_ENV_FORCE

Can be one of:

FALSE

Normal request.

TRUE

Request is urgent. The script should check whether the resource can be released successfully by force, such as by using the force option to unmount a file system.

Return Data:

If the command succeeds, the script must return no data and exit with status 0.

If the script would not be able to release the resource, it must specify the reason using the name-value pair `rcm_failure_reason` and exit with status 3.

Upon any other failure, the script must specify the failure reason using the name-value pair `rcm_failure_reason` and exit with status 1.

`preremove resourcename`

The `preremove` command is invoked prior to an attempt to remove the given *resourcename*. In response to this command the script can either release the resource (including closing the device if the device is currently opened) from the service or application it represents or indicate that it can not release the resource if the resource is critical for its service or application.

Additional environment parameter:

RCM_ENV_FORCE

Can be one of:

FALSE

Normal request.

TRUE

Request is urgent. The script should make extra effort to release the resource, such as by using the force option to unmount a file system.

Return Data:

If the command succeeds, the script must return no data and exit with status 0.

If the script cannot release the resource, it must specify the reason using the name-value pair `rcm_failure_reason` and exit with status 3.

Upon any other failure, the script must specify the failure reason using the name-value pair `rcm_failure_reason` and exit with status 1.

rcmscript(4)

postremove resourcename

The *postremove* command is invoked after the given *resourcename* has been removed.

Return Data:

If the command succeeds, the script must return no data and exit with status 0.

Upon failure, the script must specify the failure reason using the name-value pair *rcm_failure_reason* and exit with status 1.

undoremove resourcename

The *undoremove* command is invoked to undo what was done in the previous *preremove* command for the given *resourcename*. The script can bring the state of the resource to the same state it was in when the script received the *preremove* command for that resource.

Return Data:

If the command succeeds, the script must return no data and exit with status 0.

Upon failure, the script must specify the failure reason using the name-value pair *rcm_failure_reason* and exit with status 1.

Logging

A script must log all error and debug messages by writing to stdout the name-value pairs listed below. The logged messages go to *syslogd(1M)* with the *syslog* facility of *LOG_DAEMON*. See *syslog.conf(4)*.

rcm_log_err=message Logs the *message* with the syslog level of *LOG_ERR*.

rcm_log_warn=message Logs the *message* with the syslog level of *LOG_WARNING*.

rcm_log_info=message Logs the *message* with the syslog level of *LOG_INFO*.

rcm_log_debug=message Logs the *message* with the syslog level of *LOG_DEBUG*.

A script can use the environment variable *RCM_ENV_DEBUG_LEVEL* to control the amount of information to log. *RCM_ENV_DEBUG_LEVEL* is a numeric value ranging from 0 to 9, with 0 meaning log the least amount of information and 9 meaning log the most.

Installing or Removing RCM Scripts

You must use the following format to name a script:

vendor,service

where *vendor* is the stock symbol (or any distinctive name) of the vendor providing the script and *service* is the name of service the script represents.

You must be a superuser (root) to install or remove an RCM script.

Select one of the following directories where you want to place the script:

```

/etc/rcm/scripts
  Scripts for specific systems

/usr/platform/`uname -i`/lib/rcm/scripts
  Scripts for specific hardware implementation

/usr/platform/`uname -m`/lib/rcm/scripts
  Scripts for specific hardware class

/usr/lib/rcm/scripts
  Scripts for any hardware

```

Installing a Script

To install a script, copy the script to the appropriate directory from the list above, change the userid and the groupid of the script to the desired values, and send SIGHUP to rcm_daemon. For example:

```

# cp SUNW,sample.pl /usr/lib/rcm/scripts
# chown user[:group] /usr/lib/rcm/scripts/SUNW,sample.pl
# pkill -HUP -x -u root rcm_daemon

```

Removing a script

Remove the script from the appropriate directory from the list above and send SIGHUP to rcm_daemon. For example:

```

# rm /usr/lib/rcm/scripts/SUNW,sample.pl
# pkill -HUP -x -u root rcm_daemon

```

EXAMPLES

EXAMPLE 1 Site Customization RCM Script

```

#!/usr/bin/perl -w

#
# A sample site customization RCM script for a tape backup application.
#
# This script registers all tape drives in the system with RCM.
# When the system attempts to remove a tape drive by DR the script
# does the following:
#   - if the tape drive is not being used for backup, it allows the
#     DR to continue.
#   - if the tape drive is being used for backup, and when DR is not forced
#     (RCM_ENV_FORCE=FALSE) it indicates that it cannot release the
#     tape drive with appropriate error message. When forced
#     (RCM_ENV_FORCE=TRUE) it kills the tape backup application in
#     order to allow the DR to continue.
#
# This script does not implement the postremove and undoremove commands
# since there is nothing to cleanup after DR remove operation is completed
# or failed. If any cleanup is needed after the DR removal completed,
# postremove command needs to be implemented. If any cleanup is needed
# in the event of DR removal failure, undoremove command needs to be
# implemented.
#

```

        if (($f !~ /^\.\/) && ($f =~ /^[0-9]+$/)) {
            print "rcm_resource_name=/dev/rmt/$f\n";
        }
    }

    closedir(RMT);
    exit (0);
}

sub do_resourceinfo
{

```

EXAMPLE 1 Site Customization RCM Script (Continued)

```

my ($rsrc, $unit);

$rsrc = shift(@ARGV);
if ($rsrc =~ /^\/dev\/rmt\/([0-9]+)$/) {
    $unit = $1;
    print "rcm_resource_usage_info=Backup Tape Unit Number $unit\n";
    exit (0);
} else {
    print "rcm_failure_reason=Unknown tape device!\n";
    exit (1);
}
}

sub do_preremove
{
    my ($rsrc);

    $rsrc = shift(@ARGV);

    # check if backup application is using this resource
    # if (the backup application is not running on $rsrc) {
    # allow the DR to continue
    #     exit (0);
    #}
    #
    # If RCM_ENV_FORCE is FALSE deny the operation.
    # If RCM_ENV_FORCE is TRUE kill the backup application in order
    # to allow the DR operation to proceed
    #
    if ($ENV{RCM_ENV_FORCE} eq 'TRUE') {
        if ($cmd eq 'preremove') {
            # kill the tape backup application
        }
        exit (0);
    } else {
        #
        # indicate that the tape drive can not be released
        # since the device is being used for backup by the
        # tape backup application
        #
        print "rcm_failure_reason=tape backup in progress pid=...\n";
        exit (3);
    }
}
}

```

EXIT STATUS A script must exit with following exit status values:

- 0 Operation specified by the given RCM command has been executed successfully by the script. For queryremove command it also means that the script can successfully release the resource.

rcmscript(4)

- 1 An error occurred while processing the RCM command. The script should provide the error message to RCM using the name-value pair `rcm_failure_reason` before exiting.
- 2 The script does not support the given RCM command. A script must exit with this status if it cannot understand the given RCM command.
- 3 Indicates that the script cannot release the resource for `preremove` and `queryremove` commands. The script should provide a message to RCM specifying the reason for not being able to release the resource using the name-value pair `rcm_failure_reason` before exiting.

ERRORS If a script cannot successfully process an RCM command, it must supply to the RCM a message indicating the reason for failure by writing a name-value pair, in the form shown below, to stdout and exiting with the appropriate exit status.

```
rcm_failure_reason=failure_reason
```

where *failure_reason* is a localized human readable message describing the reason for failure of the RCM command.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving

SEE ALSO `gettext(1)`, `cfgadm(1M)`, `cfgadm_scsi(1M)`, `cfgadm_pci(1M)`, `syslog(3C)`, `signal(3HEAD)`, `syslog.conf(4)`, `attributes(5)`, `environ(5)`

NOTES RCM scripts are expected to properly handle all RCM commands that the script implements and to log all errors. Only root has permission to add or remove an RCM script. An ill-behaved RCM script can cause unexpected DR failures.

RCM commands are invoked only for the resources whose subsystems participate within the RCM framework. Currently, not all subsystems participate within the RCM framework.

NAME	remote – remote host description file																						
SYNOPSIS	/etc/remote																						
DESCRIPTION	<p>The systems known by <code>tip(1)</code> and their attributes are stored in an ASCII file which is structured somewhat like the <code>termcap</code> file. Each line in the file provides a description for a single <i>system</i>. Fields are separated by a colon ':'. Lines ending in a '\ ' character with an immediately following NEWLINE are continued on the next line.</p> <p>The first entry is the name(s) of the host system. If there is more than one name for a system, the names are separated by vertical bars. After the name of the system comes the fields of the description. A field name followed by an '=' sign indicates a string value follows. A field name followed by a '#' sign indicates a following numeric value.</p> <p>Entries named <code>tipbaudrate</code> are used as default entries by <code>tip</code>, as follows. When <code>tip</code> is invoked with only a phone number, it looks for an entry of the form <code>tipbaudrate</code>, where <i>baudrate</i> is the baud rate with which the connection is to be made. For example, if the connection is to be made at 300 baud, <code>tip</code> looks for an entry of the form <code>tip300</code>.</p>																						
CAPABILITIES	<p>Capabilities are either strings (<i>str</i>), numbers (<i>num</i>), or boolean flags (<i>bool</i>). A string capability is specified by <i>capability=value</i>; for example, 'dv=/dev/harris'. A numeric capability is specified by <i>capability#value</i>; for example, 'xa#99'. A boolean capability is specified by simply listing the capability.</p> <p><code>at</code> (<i>str</i>) Auto call unit type. The following lists valid 'at' types and their corresponding hardware:</p> <table border="0" style="margin-left: 20px;"> <tr><td><code>biz31f</code></td><td>Bizcomp 1031, tone dialing</td></tr> <tr><td><code>biz31w</code></td><td>Bizcomp 1031, pulse dialing</td></tr> <tr><td><code>biz22f</code></td><td>Bizcomp 1022, tone dialing</td></tr> <tr><td><code>biz22w</code></td><td>Bizcomp 1022, pulse dialing</td></tr> <tr><td><code>df02</code></td><td>DEC DF02</td></tr> <tr><td><code>df03</code></td><td>DEC DF03</td></tr> <tr><td><code>ventel</code></td><td>Ventel 212+</td></tr> <tr><td><code>v3451</code></td><td>Vadic 3451 Modem</td></tr> <tr><td><code>v831</code></td><td>Vadic 831</td></tr> <tr><td><code>hayes</code></td><td>Any Hayes-compatible modem</td></tr> <tr><td><code>at</code></td><td>Any Hayes-compatible modem</td></tr> </table> <p><code>br</code> (<i>num</i>) The baud rate used in establishing a connection to the remote host. This is a decimal number. The default baud rate is 300 baud.</p>	<code>biz31f</code>	Bizcomp 1031, tone dialing	<code>biz31w</code>	Bizcomp 1031, pulse dialing	<code>biz22f</code>	Bizcomp 1022, tone dialing	<code>biz22w</code>	Bizcomp 1022, pulse dialing	<code>df02</code>	DEC DF02	<code>df03</code>	DEC DF03	<code>ventel</code>	Ventel 212+	<code>v3451</code>	Vadic 3451 Modem	<code>v831</code>	Vadic 831	<code>hayes</code>	Any Hayes-compatible modem	<code>at</code>	Any Hayes-compatible modem
<code>biz31f</code>	Bizcomp 1031, tone dialing																						
<code>biz31w</code>	Bizcomp 1031, pulse dialing																						
<code>biz22f</code>	Bizcomp 1022, tone dialing																						
<code>biz22w</code>	Bizcomp 1022, pulse dialing																						
<code>df02</code>	DEC DF02																						
<code>df03</code>	DEC DF03																						
<code>ventel</code>	Ventel 212+																						
<code>v3451</code>	Vadic 3451 Modem																						
<code>v831</code>	Vadic 831																						
<code>hayes</code>	Any Hayes-compatible modem																						
<code>at</code>	Any Hayes-compatible modem																						

remote(4)

cm	(str) An initial connection message to be sent to the remote host. For example, if a host is reached through a port selector, this might be set to the appropriate sequence required to switch to the host.
cu	(str) Call unit if making a phone call. Default is the same as the dv field.
db	(bool) Cause tip(1) to ignore the first hangup it sees. db (dialback) allows the user to remain in tip while the remote machine disconnects and places a call back to the local machine. For more information about dialback configuration, see <i>System Administration Guide: IP Services</i>
di	(str) Disconnect message sent to the host when a disconnect is requested by the user.
du	(bool) This host is on a dial-up line.
dv	(str) Device(s) to open to establish a connection. If this file refers to a terminal line, tip attempts to perform an exclusive open on the device to insure only one user at a time has access to the port.
ec	(bool) Initialize the tip variable echocheck to on, so that tip will synchronize with the remote host during file transfer by waiting for the echo of the last character transmitted.
el	(str) Characters marking an end-of-line. The default is no characters. tip only recognizes '~' escapes after one of the characters in el, or after a RETURN.
es	(str) The command prefix (escape) character for tip.
et	(num) Number of seconds to wait for an echo response when echo-check mode is on. This is a decimal number. The default value is 10 seconds.
ex	(str) Set of non-printable characters not to be discarded when scripting with beautification turned on. The default value is "\t\n\b\f".
fo	(str) Character used to force literal data transmission. The default value is '\377'.
fs	(num) Frame size for transfers. The default frame size is equal to 1024.
hd	(bool) Initialize the tip variable halfduplex to on, so local echo should be performed.
hf	(bool) Initialize the tip variable hardwareflow to on, so hardware flow control is used.
ie	(str) Input end-of-file marks. The default is a null string ("").
nb	(bool) Initialize the tip variable beautify to off, so that unprintable characters will not be discarded when scripting.
nt	(bool) Initialize the tip variable tandem to off, so that XON/XOFF flow control will not be used to throttle data from the remote host.

nv	(bool) Initialize the <code>tip</code> variable <code>verbose</code> to <i>off</i> , so that verbose mode will be turned on.
oe	(str) Output end-of-file string. The default is a null string (""). When <code>tip</code> is transferring a file, this string is sent at end-of-file.
pa	(str) The type of parity to use when sending data to the host. This may be one of <code>even</code> , <code>odd</code> , <code>none</code> , <code>zero</code> (always set bit 8 to 0), <code>one</code> (always set bit 8 to 1). The default is <code>none</code> .
pn	(str) Telephone number(s) for this host. If the telephone number field contains an '@' sign, <code>tip</code> searches the <code>/etc/phones</code> file for a list of telephone numbers — see <code>phones(4)</code> . A '%' sign in the telephone number indicates a 5-second delay for the Ventel Modem. For Hayes-compatible modems, if the telephone number starts with an 'S', the telephone number string will be sent to the modem without the "DT", which allows reconfiguration of the modem's S-registers and other parameters; for example, to disable auto-answer: " <code>pn=S0=0DT5551234</code> "; or to also restrict the modem to return only the basic result codes: " <code>pn=S0=0X0DT5551234</code> ".
pr	(str) Character that indicates end-of-line on the remote host. The default value is '\n'.
ra	(bool) Initialize the <code>tip</code> variable <code>raise</code> to <code>on</code> , so that lower case letters are mapped to upper case before sending them to the remote host.
rc	(str) Character that toggles case-mapping mode. The default value is '\377'.
re	(str) The file in which to record session scripts. The default value is <code>tip.record</code> .
rw	(bool) Initialize the <code>tip</code> variable <code>rawftp</code> to <code>on</code> , so that all characters will be sent as is during file transfers.
sc	(bool) Initialize the <code>tip</code> variable <code>script</code> to <code>on</code> , so that everything transmitted by the remote host will be recorded.
tb	(bool) Initialize the <code>tip</code> variable <code>tabexpand</code> to <code>on</code> , so that tabs will be expanded to spaces during file transfers.
tc	(str) Indicates that the list of capabilities is continued in the named description. This is used primarily to share common capability information.

EXAMPLES **EXAMPLE 1** The capability continuation feature.

Here is a short example showing the use of the capability continuation feature:

```
UNIX-1200:\
:dv=/dev/cua0:el=^D^U^C^S^Q^O@:du:at=ventel:ie=#$:oe=^D:br#1200:
arpavax|ax:\
:pn=7654321%:tc=UNIX-1200
```

System Administration Guide: IP Services

NAME	resolv.conf – resolver configuration file						
SYNOPSIS	/etc/resolv.conf						
DESCRIPTION	<p>The <code>resolver</code> is a set of routines that provide access to the Internet Domain Name System. See <code>resolver(3RESOLV)</code>. <code>resolv.conf</code> is a configuration file that contains the information that is read by the <code>resolver</code> routines the first time they are invoked by a process. The file is designed to be human readable and contains a list of keywords with values that provide various types of <code>resolver</code> information.</p> <p>The <code>resolv.conf</code> file contains the following configuration directives:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>nameserver</code></td> <td>Specifies the Internet address in dot-notation format of a name server that the resolver is to query. Up to <code>MAXNS</code> name servers may be listed, one per keyword. See <code><resolv.h></code>. If there are multiple servers, the resolver library queries them in the order listed. If no name server entries are present, the resolver library queries the name server on the local machine. The resolver library follows the algorithm to try a name server until the query times out. It then tries the the name servers that follow, until each query times out. It repeats all the name servers until a maximum number of retries are made.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>domain</code></td> <td>Specifies the local domain name. Most queries for names within this domain can use short names relative to the local domain. If no domain entry is present, the domain is determined from <code>sysinfo(2)</code> or from <code>gethostname(3C)</code>. (Everything after the first <code>'.'</code> is presumed to be the domain name.) If the host name does not contain a domain part, the root domain is assumed. You can use the <code>LOCALDOMAIN</code> environment variable to override the domain name.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>search</code></td> <td>The search list for host name lookup. The search list is normally determined from the local domain name. By default, it contains only the local domain name. You can change the default behavior by listing the desired domain search path following the search keyword, with spaces or tabs separating the names. Most <code>resolver</code> queries will be attempted using each component of the search path in turn until a match is found. This process may be slow and will generate a lot of network traffic if the servers for the listed domains are not local. Queries will time out if no server is available for one of the domains.</td> </tr> </table>	<code>nameserver</code>	Specifies the Internet address in dot-notation format of a name server that the resolver is to query. Up to <code>MAXNS</code> name servers may be listed, one per keyword. See <code><resolv.h></code> . If there are multiple servers, the resolver library queries them in the order listed. If no name server entries are present, the resolver library queries the name server on the local machine. The resolver library follows the algorithm to try a name server until the query times out. It then tries the the name servers that follow, until each query times out. It repeats all the name servers until a maximum number of retries are made.	<code>domain</code>	Specifies the local domain name. Most queries for names within this domain can use short names relative to the local domain. If no domain entry is present, the domain is determined from <code>sysinfo(2)</code> or from <code>gethostname(3C)</code> . (Everything after the first <code>'.'</code> is presumed to be the domain name.) If the host name does not contain a domain part, the root domain is assumed. You can use the <code>LOCALDOMAIN</code> environment variable to override the domain name.	<code>search</code>	The search list for host name lookup. The search list is normally determined from the local domain name. By default, it contains only the local domain name. You can change the default behavior by listing the desired domain search path following the search keyword, with spaces or tabs separating the names. Most <code>resolver</code> queries will be attempted using each component of the search path in turn until a match is found. This process may be slow and will generate a lot of network traffic if the servers for the listed domains are not local. Queries will time out if no server is available for one of the domains.
<code>nameserver</code>	Specifies the Internet address in dot-notation format of a name server that the resolver is to query. Up to <code>MAXNS</code> name servers may be listed, one per keyword. See <code><resolv.h></code> . If there are multiple servers, the resolver library queries them in the order listed. If no name server entries are present, the resolver library queries the name server on the local machine. The resolver library follows the algorithm to try a name server until the query times out. It then tries the the name servers that follow, until each query times out. It repeats all the name servers until a maximum number of retries are made.						
<code>domain</code>	Specifies the local domain name. Most queries for names within this domain can use short names relative to the local domain. If no domain entry is present, the domain is determined from <code>sysinfo(2)</code> or from <code>gethostname(3C)</code> . (Everything after the first <code>'.'</code> is presumed to be the domain name.) If the host name does not contain a domain part, the root domain is assumed. You can use the <code>LOCALDOMAIN</code> environment variable to override the domain name.						
<code>search</code>	The search list for host name lookup. The search list is normally determined from the local domain name. By default, it contains only the local domain name. You can change the default behavior by listing the desired domain search path following the search keyword, with spaces or tabs separating the names. Most <code>resolver</code> queries will be attempted using each component of the search path in turn until a match is found. This process may be slow and will generate a lot of network traffic if the servers for the listed domains are not local. Queries will time out if no server is available for one of the domains.						

<i>sortlistaddresslist</i>	<p>The search list is currently limited to six domains and a total of 256 characters.</p> <p>Allows addresses returned by the <code>libresolv-internal</code> <code>gethostbyname()</code> to be sorted. A <code>sortlist</code> is specified by IP address netmask pairs. The netmask is optional and defaults to the natural netmask of the net. The IP address and optional network pairs are separated by slashes. Up to 10 pairs may be specified. For example:</p> <pre>sortlist 130.155.160.0/255.255.240.0 130.155.0.0</pre>
<i>options</i>	<p>Allows certain internal resolver variables to be modified. The syntax is</p> <pre>options option ...</pre> <p>where <code>option</code> is one of the following:</p> <p><code>debug</code> Sets <code>RES_DEBUG</code> in the <code>_res.options</code> field.</p> <p><code>ndots:n</code> Sets a threshold floor for the number of dots which must appear in a name given to <code>res_query()</code> before an initial absolute (as-is) query is performed. See <code>resolver(3RESOLV)</code>. The default value for <code>n</code> is 1, which means that if there are any dots in a name, the name is tried first as an absolute name before any search list elements are appended to it.</p> <p><code>timeout:n</code> <code>retrans:n</code> Sets the amount of time the resolver will wait for a response from a remote name server before retrying the query by means of a different name server. Measured in seconds, the default is <code>RES_TIMEOUT</code>. See <code><resolv.h></code>. The <code>timeout</code> and <code>retrans</code> values are the starting point for an exponential back off procedure where the <code>timeout</code> is doubled for every retransmit attempt.</p> <p><code>attempts:n</code> <code>retry:n</code> Sets the number of times the resolver will send a query to its name servers before giving up and returning an error to the calling application. The default is <code>RES_DFLRETRY</code>. See <code><resolv.h></code>.</p>

rotate
 Sets RES_ROTATE in `_res.options`. The name servers are queried round-robin from among those listed. The query load is spread among all listed servers, rather than having all clients try the first listed server first every time.

no-check-names
 Sets RES_NOCHECKNAME in `_res.options`. This disables the modern BIND checking of incoming host names and mail names for invalid characters such as underscore (`_`), non-ASCII, or control characters.

inet6
 Sets RES_USE_INET6 in `_res.options`. In the Solaris BIND port, this has no effect on `gethostbyname(3NSL)`. To retrieve IPv6 addresses or IPv4 addresses in mapped form, use `getipnodebyname(3SOCKET)` instead of setting `inet6`.

The `domain` and `search` keywords are mutually exclusive. If more than one instance of these keywords is present, the last instance takes precedence

You can override the `search` keyword of the system `resolv.conf` file on a per-process basis by setting the environment variable `LOCALDOMAIN` to a space-separated list of search domains.

You can amend the `options` keyword of the system `resolv.conf` file on a per-process basis by setting the environment variable `RES_OPTIONS` to a space-separated list of resolver options.

The keyword and value must appear on a single line. Start the line with the keyword, for example, `nameserver`, followed by the value, separated by white space.

FILES `/etc/resolv.conf`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard BIND 8.2.4

rmmount.conf(4)

NAME	rmmount.conf – removable media mounter configuration file						
SYNOPSIS	/etc/rmmount.conf						
DESCRIPTION	<p>The <code>rmmount.conf</code> file contains the <code>rmmount(1M)</code> configuration information. This file describes where to find shared objects that perform actions on file systems after identifying and mounting them. The <code>rmmount.conf</code> file is also used to share file systems on removable media. It can also direct the <code>rmmount</code> utility to run <code>fsck</code> on one or more file systems before mounting them, with the <code>fsck</code> command line options specified in <code>rmmount.conf</code>.</p> <p>Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further actions will be executed. This allows the function to control which applications are executed. For example, <code>action_filemgr</code> always returns 0 if the File Manager is running, thereby preventing subsequent actions from being executed.</p> <p>To execute an action after a medium has been inserted and while the File Manager is not running, list the action after <code>action_filemgr</code> in the <code>rmmount.conf</code> file. To execute an action before the File Manager becomes aware of the medium, list the action before <code>action_filemgr</code> in the <code>rmmount.conf</code> file.</p> <p>The syntax for the <code>rmmount.conf</code> file is as follows:</p> <pre># File system identification ident filesystem_type shared_object media_type [media_type ...] # Actions action media_type shared_object args_to_so # File system sharing share media_or_file_system share_command_options # Mount command options mount media_or_file_system [file_system_spec] -o mount_command_options # Optionally fsck command options fsck media_type filesystem_type -o fsck_command_options</pre> <p>Explanations of the syntax for the File system identification fields are as follows:</p> <table><tr><td><i>filesystem_type</i></td><td>An ASCII string used as the file system type flag of the mount command (see the <code>-F</code> option of <code>mount(1M)</code>). It is also used to match names passed to <code>rmmount(1M)</code> from Volume Management.</td></tr><tr><td><i>shared_object</i></td><td>Programs that identify file systems and perform actions. This <i>shared_object</i> is found at <code>/usr/lib/fs/filesystem_type/shared_object</code>.</td></tr><tr><td><i>media_type</i></td><td>The type of medium where this file system resides. Legal values are <code>cdrom</code>, <code>floppy</code>, <code>jaz</code>, <code>rmdisk</code>, and</td></tr></table>	<i>filesystem_type</i>	An ASCII string used as the file system type flag of the mount command (see the <code>-F</code> option of <code>mount(1M)</code>). It is also used to match names passed to <code>rmmount(1M)</code> from Volume Management.	<i>shared_object</i>	Programs that identify file systems and perform actions. This <i>shared_object</i> is found at <code>/usr/lib/fs/filesystem_type/shared_object</code> .	<i>media_type</i>	The type of medium where this file system resides. Legal values are <code>cdrom</code> , <code>floppy</code> , <code>jaz</code> , <code>rmdisk</code> , and
<i>filesystem_type</i>	An ASCII string used as the file system type flag of the mount command (see the <code>-F</code> option of <code>mount(1M)</code>). It is also used to match names passed to <code>rmmount(1M)</code> from Volume Management.						
<i>shared_object</i>	Programs that identify file systems and perform actions. This <i>shared_object</i> is found at <code>/usr/lib/fs/filesystem_type/shared_object</code> .						
<i>media_type</i>	The type of medium where this file system resides. Legal values are <code>cdrom</code> , <code>floppy</code> , <code>jaz</code> , <code>rmdisk</code> , and						

zip.

Explanations of the syntax for the `Actions` fields are as follows.

<i>media_type</i>	Type of medium. This argument is passed in from Volume Management as <code>VOLUME_TYPE</code> .
<i>shared_object</i>	Programs that identify file systems and perform actions. If <i>shared_object</i> starts with '/' (slash), the full path name is used; otherwise, <code>/usr/lib/rmmount</code> is prepended to the name.
<i>args_to_so</i>	Arguments passed to the <i>shared_object</i> . These arguments are passed in as an <i>argc</i> and <i>argv</i> [],

The definition of the interface to `Actions` is located in `/usr/include/rmmount.h`.

Explanations of the syntax for the `File system sharing` fields are as follows.

<i>media_or_file_system</i>	Either the type of medium or the specific file system to share.
<i>share_command_options</i>	Options of the <code>share</code> command. See <code>share(1M)</code> for more information about these options.

Explanations of the syntax for the `Mount command options` fields are as follows:

<i>media_or_file_system</i>	Either the type of medium or the specific file system to share.
<i>file_system_spec</i>	Specifies one or more file systems to which this line applies. Defaults to "all" file system types.
<i>mount_command_options</i>	One or more options to be passed to the <code>mount</code> command. Multiple options require a space delimiter.

Explanations of the syntax for the `fsck command options` fields are as follows:

<i>media_type</i>	The type of removable medium. A Bourne shell regular expression that matches names of file system media whose aliases are listed under <code>/vol/dev/aliases</code> . Examples include <code>cdrom0</code> , <code>cdrom1</code> , <code>cdrom*</code> , <code>jaz0</code> , <code>jaz1</code> , and <code>jaz*</code> .
<i>filesystem_type</i>	The type of file system, for example, <code>ufs</code> or <code>hfs</code> , that resides on the medium specified in <i>media_type</i> .
<i>fsck_command_options</i>	One or more options to be passed to <code>fsck(1M)</code> . Multiple options must be separated by spaces.

The algorithm for the `fsck` configuration line is as follows:

1. The `fsck` configuration line tells `rmmount` to run `fsck` on *filesystem_type*, as described above. The *filesystem_type* must be correct for the *media_type* specified.
2. If *filesystem_type* is not present, `rmmount` runs `fsck` on all file systems on all media that match *media_type*.

rmmount.conf(4)

3. If `rmmount.conf` contains no `fsck` configuration line or contains an `fsck` configuration line with a `media_type` that does not match a medium's alias, `rmmount` does not run `fsck` on the removable medium's file system, unless `mount` reports that the file system's dirty bit is set.

Default Values The following is an example of an `rmmount.conf` file:

```
#
# Removable Media Mounter configuration file.
#
# File system identification
ident hsfs ident_hsfs.so cdrom
ident ufs ident_ufs.so cdrom floppy rmdisk pcmem
ident pcfs ident_pcfs.so floppy rmdisk pcmem
ident udfs ident_udfs.so cdrom floppy

# Actions
action cdrom action_filemgr.so
action floppy action_filemgr.so
action rmdisk action_filemgr.so
```

EXAMPLES **EXAMPLE 1** Sharing of Various File Systems

The following examples show how various file systems are shared using the `share` syntax for the `rmmount.conf` file. These lines are added after the `Actions` entries.

```
share cdrom*
    Shares all CD-ROMs via NFS and applies no access restrictions.

share solaris_2.x*
    Shares CD-ROMs named solaris_2.x* with no access restrictions.

share cdrom* -o ro=engineering
    Shares all CD-ROMs via NFS but exports only to the "engineering" netgroup.

share solaris_2.x* -d distribution CD
    Shares CD-ROMs named solaris_2.x* with no access restrictions and with the
    description that it is a distribution CD-ROM.

share floppy0
    Shares the file system of any floppy inserted into floppy drive 0.

share jaz0
    Shares the file system on Jaz drive 0.
```

EXAMPLE 2 Customizing mount Operations

The following examples show how different `mount` options could be used to customize how `rmmount` mounts various media:

```
mount cdrom* hsfs -o nrr
    Mounts all High Sierra CD-ROMs with the nrr (no Rock Ridge extensions) option
    (see mount_hsfs(1M)).
```

EXAMPLE 2 Customizing mount Operations *(Continued)*

```
mount floppy1 -o ro
```

Will always mount the second floppy disk read-only (for all file system types).

```
mount floppy1 -o ro foldcase
```

Will always mount the second floppy disk read-only (for all file system types) and pass the `foldcase` mount option.

```
mount jaz1 -o ro
```

Mounts the medium in Jaz drive 1 read-only, for all file system types.

EXAMPLE 3 Telling rmmount to Check File Systems Before Mounting Them

The following examples show how to tell `rmmount` to check file systems with `fsck` before mounting them, and how to specify the command line options to be used with `fsck`:

```
fsck floppy* ufs -o f
```

Performs a full file system check on any UFS floppies, ignoring the clean flag, before mounting them.

```
fsck floppy* ufs -o p
```

Uses the `fsck p` (preen) flag for all UFS floppies.

```
fsck cdrom* -o f
```

Tells `rmmount` to run `fsck` before mounting any file system on CD-ROM.

```
fsck jaz* ufs -o f
```

Tells `rmmount` to perform a full file system check on any UFS Jaz media, ignoring the clean flag, before mounting them.

SEE ALSO `volcancel(1)`, `volcheck(1)`, `volmissing(1)`, `mount(1M)`, `mount_hsf(1M)`, `rmmount(1M)`, `share(1M)`, `vold(1M)`, `vold.conf(4)`, `volfs(7FS)`

NOTES When using the `mount` options line, verify that the specified options will work with the specified file system types. The `mount` command will fail if an incorrect mount option/file system combination is specified. Multiple `mount` options require a space delimiter.

rmtab(4)

NAME	rmtab – remote mounted file system table
SYNOPSIS	/etc/rmtab
DESCRIPTION	<p>rmtab contains a table of filesystems that are remotely mounted by NFS clients. This file is maintained by mountd(1M), the mount daemon. The data in this file should be obtained only from mountd(1M) using the MOUNTPROC_DUMP remote procedure call.</p> <p>The file contains a line of information for each remotely mounted filesystem. There are a number of lines of the form:</p> <p><i>hostname:fsname</i>The mount daemon adds an entry for any client that successfully executes a mount request and deletes the appropriate entries for an unmount request.</p> <p>Lines beginning with a hash (' #') are commented out. These lines are removed from the file by mountd(1M) when it first starts up. Stale entries may accumulate for clients that crash without sending an unmount request.</p>
FILES	/etc/rmtab
SEE ALSO	mountd(1M), showmount(1M)

NAME	rpc – rpc program number data base
SYNOPSIS	/etc/rpc
DESCRIPTION	<p>The <code>rpc</code> file is a local source containing user readable names that can be used in place of RPC program numbers. The <code>rpc</code> file can be used in conjunction with or instead of other <code>rpc</code> sources, including the NIS maps “<code>rpc.byname</code>” and “<code>rpc.bynumber</code>” and the NIS+ table “<code>rpc</code>”.</p> <p>The <code>rpc</code> file has one line for each RPC program name. The line has the following format:</p> <p><i>name-of-the-RPC-program</i> <i>RPC-program-number</i> <i>aliases</i> Items are separated by any number of blanks and/or tab characters. A “#” indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file.</p>
EXAMPLES	<p>EXAMPLE 1 RPC Database</p> <p>Below is an example of an RPC database:</p> <pre># # rpc # rpcbind 100000 portmap sunrpc portmapper rusersd 100002 rusers nfs 100003 nfsprog mountd 100005 mount showmount walld 100008 rwall shutdown sprayd 100012 spray llockmgr 100020 nlockmgr 100021 status 100024 bootparam 100026 keyserv 100029 keyserver</pre>
FILES	/etc/nsswitch.conf
SEE ALSO	nsswitch.conf(4)

rpc.nisd(4)

NAME	rpc.nisd – configuration file for NIS+ service daemon				
SYNOPSIS	/etc/default/rpc.nisd				
DESCRIPTION	<p>The <code>rpc.nisd</code> file specifies configuration information for the <code>rpc.nisd(1M)</code> server. Configuration information can come from a combination of three places. It can be derived from LDAP. It can be specified in the <code>rpc.nisd</code> file. It can be specified on the <code>rpc.nisd(1M)</code> command line. The values in the <code>rpc.nisd</code> file override values obtained from the LDAP server. Command line values supersede values in the configuration file.</p> <p>The <code>NIS+LDAPmapping(4)</code> file contains mapping information connecting NIS+ object data to LDAP entries. See the <code>NIS+LDAPmapping(4)</code> manual page for an overview of the setup needed to map NIS+ data to or from LDAP.</p>				
Attributes	<p>The <code>rpc.nisd(1M)</code> server recognizes the following attributes. Any values specified for these attributes in the <code>rpc.nisd</code> file, including an empty value, override values obtained from LDAP. However, the <code>nisplusLDAPconfig*</code> values are read from the <code>rpc.nisd</code> file or the command line only. They are not obtained from LDAP.</p> <p>The following are attributes used for initial configuration.</p> <p><code>nisplusLDAPconfigDN</code> The DN for configuration information. If empty, all other <code>nisplusLDAPconfig*</code> values are ignored, in the expectation that all attributes are specified in this file or on the command line. When <code>nisplusLDAPconfigDN</code> is not specified at all, the DN is derived from the NIS+ domain name by default. If the domain name is <code>x.y.z.</code>, the default <code>nisplusLDAPconfigDN</code> is:</p> <pre>nisplusLDAPconfigDN=dc=x,dc=y,dc=z</pre> <p><code>nisplusLDAPconfigPreferredServerList</code> The list of servers to use for the configuration phase. The syntax is the same as <code>preferredServerList</code>, which is described in <i>RFC 2307bis</i>. See NOTES. There is no default. The following is an example of a value for <code>nisplusLDAPconfigPreferredServerList</code>:</p> <pre>nisplusLDAPconfigPreferredServerList=127.0.0.1:389</pre> <p><code>nisplusLDAPconfigAuthenticationMethod</code> The authentication method(s) used to obtain the configuration information. The syntax is the same as the syntax for the <code>authenticationMethod</code> attribute, which is described in <i>RFC 2307bis</i>. See NOTES. The recognized values for <code>nisplusLDAPconfigAuthenticationMethod</code> are:</p> <table><tr><td><code>none</code></td><td>No authentication attempted.</td></tr><tr><td><code>simple</code></td><td>Password of proxy user sent in the clear to the LDAP server.</td></tr></table>	<code>none</code>	No authentication attempted.	<code>simple</code>	Password of proxy user sent in the clear to the LDAP server.
<code>none</code>	No authentication attempted.				
<code>simple</code>	Password of proxy user sent in the clear to the LDAP server.				

<code>sasl/cram-md5</code>	Use SASL/CRAM-MD5 authentication. This authentication method may not be supported by all LDAP servers. A password must be supplied.
<code>sasl/digest-md5</code>	Use SASL/DIGEST-MD5 authentication. This authentication method may not be supported by all LDAP servers. A password must be supplied.

There is no default value. The following is an example of a value for `nisplusLDAPconfigAuthenticationMethod`:

```
nisplusLDAPconfigAuthenticationMethod=simple
```

`nisplusLDAPconfigTLS`

The transport layer security used for the connection to the server. The recognized values are:

- `none` No encryption of transport layer data. This is the default value.
- `ssl` SSL encryption of transport layer data. A certificate is required.

Export and import control restrictions may limit the availability of transport layer security.

`nisplusLDAPconfigTLSCertificateDBPath`

The name of the file containing the certificate database. The default path is `/var/nis`, and the default file name is `cert7.db`.

`nisplusLDAPconfigProxyUser`

The proxy user used to obtain configuration information. There is no default value. If the value ends with a comma, the value of the `nisplusLDAPconfigDN` attribute is appended. For example:

```
nisplusLDAPconfigProxyUser=cn=nisplusAdmin,ou=People,
```

`nisplusLDAPconfigProxyPassword`

The password that should be supplied to LDAP for the proxy user when the authentication method requires one. In order to avoid having this password publically visible on the machine, the password should only appear in the mapping file, and the file should have an appropriate owner, group, and file mode. There is no default value.

The following are attributes used for data retrieval. Except as noted, their syntax is as specified in *RFC 2307bis*. See NOTES. The object class name used for these attributes is `nisplusLDAPconfig`.

`preferredServerList`

The list of servers to use when reading or writing mapped NIS+ data from or to LDAP. There is no default value. For example:

```
preferredServerList=127.0.0.1:389
```

rpc.nisd(4)

authenticationMethod

The authentication method to use when reading or writing mapped NIS+ data from or to LDAP. For recognized values, see the `LDAPconfigAuthenticationMethod` attribute. There is no default value. For example,

```
authenticationMethod=simple
```

nisplusLDAPTLS

The transport layer security to use when reading or writing NIS+ data from or to LDAP. For recognized values, see the `nisplusLDAPconfigTLS` attribute. The default value is none. This attribute is not defined in *RFC 2307bis*. See NOTES. Note that export and import control restrictions may limit the availability of transport layer security.

nisplusLDAPTLSCertificateDBPath

The name of the file containing the certificate DB. For recognized and default values, see the `nisplusLDAPconfigTLSCertificateDBPath` attribute. This attribute is not defined in *RFC 2307bis*. See NOTES.

defaultSearchBase

The default portion of the DN to use when reading or writing mapped NIS+ data from or to LDAP. The default is derived from the value of the `baseDomain` attribute, which in turn usually defaults to the NIS+ domain name. If `nisplusLDAPbaseDomain` has the value `x.y.z`, the default `defaultSearchBase` is `dc=x,dc=y,dc=z`. See the following sample attribute value:

```
defaultSearchBase=dc=somewhere,dc=else
```

nisplusLDAPbaseDomain

The domain to append when NIS+ object names are not fully qualified. The default is the domain the `rpc.nisd` daemon is serving, or the first such domain, if there is more than one candidate.

nisplusLDAPproxyUser

Proxy user used by the `rpc.nisd` to read or write from or to LDAP. Assumed to have the appropriate permission to read and modify LDAP data. There is no default value. If the value ends in a comma, the value of the `defaultSearchBase` attribute is appended. For example:

```
nisplusLDAPproxyUser=cn=nisplusAdmin,ou=People,
```

nisplusLDAPproxyPassword

The password that should be supplied to LDAP for the proxy user when the authentication method so requires. In order to avoid having this password publically visible on the machine, the password should only appear in the mapping file, and the file should have an appropriate owner, group, and file mode. There is no default value.

nisplusLDAPbindTimeout

nisplusLDAPsearchTimeout

nisplusLDAPmodifyTimeout

`nisplusLDAPaddTimeout`

`nisplusLDAPdeleteTimeout`

Establish timeouts for LDAP bind, search, modify, add, and delete operations, respectively. The default value is 15 seconds for each one. Decimal values are allowed.

`nisplusLDAPsearchTimeLimit`

Establish a value for the `LDAP_OPT_TIMELIMIT` option, which suggests a time limit for the search operation on the LDAP server. The server may impose its own constraints on possible values. See your LDAP server documentation. The default is the `nisplusLDAPsearchTimeout` value. Only integer values are allowed.

Since the `nisplusLDAPsearchTimeout` limits the amount of time the client `rpc.nisd` will wait for completion of a search operation, setting the `nisplusLDAPsearchTimeLimit` larger than the `nisplusLDAPsearchTimeout` is not recommended.

`nisplusLDAPsearchSizeLimit`

Establish a value for the `LDAP_OPT_SIZELIMIT` option, which suggests a size limit, in bytes, for the search results on the LDAP server. The server may impose its own constraints on possible values. See your LDAP server documentation. The default is zero, which means unlimited. Only integer values are allowed.

`nisplusLDAPfollowReferral`

Determines if the `rpc.nisd` should follow referrals or not. Recognized values are `yes` and `no`. The default value is `no`.

`nisplusNumberOfServiceThreads`

Sets the maximum number of RPC service threads that the `rpc.nisd` may use. Note that the `rpc.nisd` may create additional threads for certain tasks, so that the actual number of threads running may be larger than the `nisplusNumberOfServiceThreads` value.

The value of this attribute is a decimal integer from zero to $(2^{31})-1$, inclusive. Zero, which is the default, sets the number of service threads to three plus the number of CPUs available when the `rpc.nisd` daemon starts. For example:

```
nisplusNumberOfServiceThreads=16
```

The following attributes specify the action to be taken when some event occurs. The values are all of the form `event=action`. The default action is the first one listed for each event.

`nisplusLDAPinitialUpdateAction`

Provides the optional capability to update all NIS+ data from LDAP, or vice versa, when the `rpc.nisd` starts. Depending on various factors such as both NIS+ and LDAP server and network performance, as well as the amount of data to be uploaded or downloaded, these operations can consume very significant CPU and memory resources. During upload and download, the `rpc.nisd` has not yet registered with `rpcbind`, and provides no NIS+ service. When data is downloaded

rpc.nisd(4)

from LDAP, any new items added to the `rpc.nisd`'s database get a TTL as for an initial load. See the description for the `nisplusLDAPentryTtl` attribute on `NIS+LDAPmapping(4)`.

`none` No initial update in either direction. This is the default.

`from_ldap` Causes the `rpc.nisd` to fetch data for all NIS+ objects it serves, and for which mapping entries are available, from the LDAP repository.

`to_ldap` The `rpc.nisd` writes all NIS+ objects for which it is the master server, and for which mapping entries are available, to the LDAP repository.

`nisplusLDAPinitialUpdateOnly`
Use in conjunction with `nisplusLDAPinitialUpdateAction`.

`no` Following the initial update, the `rpc.nisd` starts serving NIS+ requests. This is the default.

`yes` The `rpc.nisd` exits after the initial update. It is ignored if specified together with `nisplusLDAPinitialUpdateAction=none`.

`nisplusLDAPretrieveErrorAction`
If an error occurs while trying to retrieve an entry from LDAP, one of the following actions can be selected:

`use_cached` Action according to `nisplusLDAPrefreshError` below. This is the default.

`retry` Retry the retrieval the number of time specified by `nisplusLDAPretrieveErrorAttempts`, with the `nisplusLDAPretrieveErrorTimeout` value controlling the wait between each attempt.

`try_again`
`unavail`
`no_such_name` Return `NIS_TRYAGAIN`, `NIS_UNAVAIL`, or `NIS_NOSUCHNAME`, respectively, to the client. Note that the client code may not be prepared for this and can react in unexpected ways.

`nisplusLDAPretrieveErrorAttempts`
The number of times a failed retrieval should be retried. The default is unlimited. The `nisplusLDAPretrieveErrorAttempts` value is ignored unless `nisplusLDAPretrieveErrorAction=retry..`

`nisplusLDAPretrieveErrorTimeout`
The timeout (in seconds) between each new attempt to retrieve LDAP data. The default is 15 seconds. The value for `nisplusLDAPretrieveErrorTimeout` is ignored unless `nisplusLDAPretrieveErrorAction=retry..`

`nisplusLDAPstoreErrorAction`
An error occurred while trying to store data to the LDAP repository.

<code>retry</code>	Retry operation <code>nisplusLDAPstoreErrorAttempts</code> times with <code>nisplusLDAPstoreErrorTimeout</code> seconds between each attempt. Note that this may tie up a thread in the <code>rpc.nisd</code> daemon. This is the default.
<code>system_error</code>	Return <code>NIS_SYSTEMERROR</code> to the client.
<code>unavail</code>	Return <code>NIS_UNAVAIL</code> to the client. Note that the client code may not be prepared for this and can react in unexpected ways.
<code>nisplusLDAPstoreErrorAttempts</code>	The number of times a failed attempt to store should be retried. The default is unlimited. The value for <code>nisplusLDAPstoreErrorAttempts</code> is ignored unless <code>nisplusLDAPstoreErrorAction=retry</code> .
<code>nisplusLDAPstoreErrorTimeout</code>	The timeout, in seconds, between each new attempt to store LDAP data. The default is 15 seconds. The <code>nisplusLDAPstoreErrorTimeout</code> value is ignored unless <code>nisplusLDAPstoreErrorAction=retry</code> .
<code>nisplusLDAPrefreshErrorAction</code>	An error occurred while trying to refresh a cache entry.
<code>continue_using</code>	Continue using expired cache entry, if one is available. Otherwise, the action is <code>retry</code> . This is the default.
<code>retry</code>	Retry operation <code>nisplusLDAPrefreshErrorAttempts</code> times with <code>nisplusLDAPrefreshErrorTimeout</code> seconds between each attempt. Note that this may tie up a thread in the <code>rpc.nisd</code> daemon.
<code>cache_expired</code> <code>tryagain</code>	Return <code>NIS_CACHEEXPIRED</code> or <code>NIS_TRYAGAIN</code> , respectively, to the client. Note that the client code may not be prepared for this and could can react in unexpected ways.
<code>nisplusLDAPrefreshErrorAttempts</code>	The number of times a failed refresh should be retried. The default is unlimited. This applies to the <code>retry</code> and <code>continue_using</code> actions, but for the latter, only when there is no cached entry.
<code>nisplusLDAPrefreshErrorTimeout</code>	The timeout (in seconds) between each new attempt to refresh data. The default is 15 seconds. The value for <code>nisplusLDAPrefreshErrorTimeout</code> applies to the <code>retry</code> and <code>continue_using</code> actions.
<code>nisplusThreadCreationErrorAction</code>	The action to take when an error occurred while trying to create a new thread. This only applies to threads controlled by the <code>rpc.nisd</code> daemon not to RPC service

rpc.nisd(4)

threads. An example of threads controlled by the `rpc.nisd` daemon are those created to serve `nis_list(3NSL)` with `callback`, as used by `niscat(1)` to enumerate tables.

`pass_error` Pass on the thread creation error to the client, to the extent allowed by the available NIS+ error codes. The error might be `NIS_NOMEMORY`, or another resource shortage error. This action is the default.

`retry` Retry operation `nisplusThreadCreationErrorAttempts` times, waiting `nisplusThreadCreationErrorTimeout` seconds between each attempt. Note that this may tie up a thread in the `rpc.nisd` daemon.

`nisplusThreadCreationErrorAttempts`

The number of times a failed thread creation should be retried. The default is unlimited. The value for `nisplusThreadCreationErrorAttempts` is ignored unless the `nisplusThreadCreationErrorAction=retry`.

`nisplusThreadCreationErrorTimeout`

The number of seconds to wait between each new attempt to create a thread. The default is 15 seconds. Ignored unless `nisplusThreadCreationErrorAction=retry`.

`nisplusDumpError`

An error occurred during a full dump of a NIS+ directory from the master to a replica. The replica can:

`retry` Retry operation `nisplusDumpErrorAttempts` times waiting `nisplusDumpErrorTimeout` seconds between each attempt. Note that this may tie up a thread in the `rpc.nisd`.

`rollback` Try to roll back the changes made so far before retrying per the `retry` action. If the rollback fails or cannot be performed due to the selected `ResyncServiceAction` level, the `retry` action is selected.

`nisplusDumpErrorAttempts`

The number of times a failed full dump should be retried. The default is unlimited. When the number of retry attempts has been used up, the full dump is abandoned, and will not be retried again until a `resync` fails because no update time is available.

`nisplusDumpErrorTimeout`

The number of seconds to wait between each attempt to execute a full dump. The default is 120 seconds.

`nisplusResyncService`

Type of NIS+ service to be provided by a replica during `resync`, that is, data transfer from NIS+ master to NIS+ replica. This includes both partial and full `resyncs`.

`from_copy` Service is provided from a copy of the directory to be `resynced` while the `resync` is in progress. Rollback is

possible if an error occurs. Note that making a copy of the directory may require a significant amount of time, depending on the size of the tables in the directory and available memory on the system.

`directory_locked` While the resync for a directory is in progress, it is locked against access. Operations to the directory are blocked until the resync is done. Rollback is not possible.

`from_live` The replica database is updated in place. Rollback is not possible. If there are dependencies between individual updates in the resync, clients may be exposed to data inconsistencies during the resync. In particular, directories or tables may disappear for a time during a full dump.

`nisplusUpdateBatching`

How updates should be batched together on the master.

`accumulate` Accumulate updates for at least `nisplusUpdateBatchingTimeout` seconds. Any update that comes in before the timeout has occurred will reset the timeout counter. Thus, a steady stream of updates less than `nisplusUpdateBatchingTimeout` seconds apart could delay pinging replicas indefinitely.

`bounded_accumulate` Accumulate updates for at least `nisplusUpdateBatchingTimeout` seconds. The default value for `timeout` is 120 seconds. Incoming updates do not reset the timeout counter, so replicas will be informed once the initial timeout has expired.

`none` Updates are not batched. Instead, replicas are informed immediately of any update. While this should maximize data consistency between master and replicas, it can also cause considerable overhead on both master and replicas.

`nisplusUpdateBatchingTimeout`

The minimum time (in seconds) during which to accumulate updates. Replicas will not be pinged during this time. The default is 120 seconds.

`nisplusLDAPmatchFetchAction`

A NIS+ match operation, that is, any search other than a table enumeration, will encounter one of the following situations:

1. Table believed to be entirely in cache, and all cached entries are known to be valid. The cached tabled data is authoritative for the match operation.
2. Table wholly or partially cached, but there may be individual entries that have timed out.

3. No cached entries for the table. Always attempt to retrieve matching data from LDAP.

When the table is wholly or partially cached, the action for the `nisplusLDAPmatchFetchAction` attribute controls whether or not the LDAP repository is searched:

<code>no_match_only</code>	Only go to LDAP when there is no match at all on the search of the available NIS+ data, or the match includes at least one entry that has timed out.
<code>always</code>	Always make an LDAP lookup.
<code>never</code>	Never make an LDAP lookup.

Storing Configuration Attributes in LDAP

Most attributes described on this man page, as well as those from `NIS+LDAPmapping(4)`, can be stored in LDAP. In order to do so, you will need to add the following definitions to your LDAP server, which are described here in LDIF format suitable for use by `ldapadd(1)`. The attribute and object class OIDs are examples only.

Your LDAP server should know the attributes and object classes defined in *RFC2307bis*. See NOTES. However, if it does not, the following definitions are sufficient for the purposes of NIS+/LDAP mapping:

```
dn: cn=schema
changetype: modify
add: attributetypes
OIDattributetypes: ( 1.3.6.1.4.1.11.1.3.1.1.1 NAME 'defaultSearchBase' \
DESC 'Default LDAP base DN used by a DUA' \
EQUALITY distinguishedNameMatch \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.12 SINGLE-VALUE )
attributetypes: ( 1.3.6.1.4.1.11.1.3.1.1.2 NAME 'preferredServerList' \
DESC 'Preferred LDAP server host addresses used by DUA' \
EQUALITY caseIgnoreMatch \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 SINGLE-VALUE )
attributetypes: ( 1.3.6.1.4.1.11.1.3.1.1.6 NAME 'authenticationMethod' \
DESC 'Authentication method used to contact the DSA' \
EQUALITY caseIgnoreMatch \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 SINGLE-VALUE )
```

The following are LDIF data to create the configuration attributes and object class:

```
dn: cn=schema

        nisplusLDAPattributeFromColumn ) )

```

Create a file containing the following LDIF data. Substitute your actual search base for *searchBase*, and your fully qualified domain name for *domain*:

```

dn: cn=domain,searchBase
cn: domain
objectClass: top
objectClass: nisplusLDAPconfig

```

Use this file as input to the `ldapadd(1)` command in order to create the NIS+/LDAP configuration entry. Initially, the entry is empty. You can use the `ldapmodify(1)` command to add configuration attributes.

rpc.nisd(4)

EXAMPLES

EXAMPLE 1 Creating a NIS+/LDAP Configuration Entry

To set the `nisplusNumberOfServiceThreads` attribute to 32, create the following file and use it as input to `ldapmodify(1)`:

```
dn: cn=domain,searchBase
nisplusNumberOfServiceThreads: 32
```

NOTES

RFC 2307bis is an IETF informational document in draft stage that defines an approach for using LDAP as a naming service.

NAME	rpld.conf – Remote Program Load (RPL) server configuration file
SYNOPSIS	/etc/rpld.conf
DESCRIPTION	<p>The /etc/rpld.conf file contains the configuration information for operation of rpld, the RPL-based network boot server. It is a text file containing keyword-value pairs and comments. The keyword-value pairs specify the value to use for parameters used by the RPL server. Comments can be entered by starting the line using the # character. The user can add comments to the file for customized configurations. Alternate RPL server configuration files can be specified when running the RPL server by supplying a configuration file similar to the default configuration file.</p>
Keywords	<p>All keywords are case-sensitive. Not all keywords must be present. (However, note that the end keyword at the end of the file must be present.) If a keyword is not present, internal defaults, which are the default values described here, will be used. Keyword-value pairs are specified by:</p> <pre>keyword = value</pre> <p>DebugLevel Specify the number of error, warning, and information messages to be generated while the RPL server is running. The valid range is 0-9. A value of 0 means no message at all, while a value of 9 will generate the most messages. The default is 0. Note that it is best to limit the value to 8 or below; use of level 9 may generate so many debug messages that the performance of the RPL server may be impacted.</p> <p>DebugDest A numeric value specifying where to send the messages to:</p> <pre>0 = standard output 1 = syslogd 2 = log file</pre> <p>The default is 2.</p> <p>MaxClients A numeric value specifying the maximum number of simultaneous network boot clients to be in service. A value of -1 means unlimited except where system resources is the limiting factor. Any positive value will set a limit on the number of clients to be in service at the same time unless system resource constraints come in before the limit. The default is -1.</p> <p>BackGround A numeric value indicating whether the RPL server should run in the background or not. A 0 means run in the background and a 1 means do not run in the background. The difference is whether the server will relinquish the controlling terminal or not. The default is 1.</p> <p>FrameSize The default size of data frames to be used to send bootfile data to the network boot clients. This size should not exceed the limits imposed by the underlying physical media. For</p>

rpld.conf(4)

ethernet/802.3, the maximum physical frame size is 1500 octets. The default is 1500. Note that the protocol overhead of LLC1 and RPL is 32 octets, resulting in a maximum data length of 1468 octets.

- LogFile** The log file to which messages will be sent if `DebugDest` is set to 2 (the default). The default file is `var/spool/rpld.log`.
- StartDelay** The initial delay factor to use to control the speed of downloading. In the default mode of operation, the downloading process does not wait for a positive acknowledgment from the client before the next data frame is sent. In the case of a fast server and slow client, data overrun can result and requests for retransmission will be frequent. By using a delay factor, the speed of data transfer is controlled to avoid retransmission requests. Note that the unit of delay is machine dependent and bears no correlation with the actual time delayed.
- DelayGran** Delay granularity. If the initial delay factor is not suitable and the rate of downloading is either too fast or too slow, retransmission requests from the clients will be used to adjust the delay factor either upward (to slow down the data rate) or downward (to speed up the data rate). The delay granularity is used as the delay delta for adjustment.
- end** Keyword at the end of the file. It must be present.

FILES `/etc/rpld.conf`
`/usr/sbin/rpld`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	rt_dptbl – real-time dispatcher parameter table
DESCRIPTION	<p>The process scheduler (or dispatcher) is the portion of the kernel that controls allocation of the CPU to processes. The scheduler supports the notion of scheduling classes where each class defines a scheduling policy, used to schedule processes within that class. Associated with each scheduling class is a set of priority queues on which ready to run processes are linked. These priority queues are mapped by the system configuration into a set of global scheduling priorities which are available to processes within the class. The dispatcher always selects for execution the process with the highest global scheduling priority in the system. The priority queues associated with a given class are viewed by that class as a contiguous set of priority levels numbered from 0 (lowest priority) to n (highest priority—a configuration dependent value). The set of global scheduling priorities that the queues for a given class are mapped into might not start at zero and might not be contiguous, depending on the configuration.</p> <p>The real-time class maintains an in-core table, with an entry for each priority level, giving the properties of that level. This table is called the real-time dispatcher parameter table (<code>rt_dptbl</code>). The <code>rt_dptbl</code> consists of an array (<code>config_rt_dptbl []</code>) of parameter structures (<code>struct rtdpent_t</code>), one for each of the n priority levels. The structure are accessed via a pointer, (<code>rt_dptbl</code>), to the array. The properties of a given priority level i are specified by the ith parameter structure in this array (<code>rt_dptbl [i]</code>).</p> <p>A parameter structure consists of the following members. These are also described in the <code>/usr/include/sys/rt.h</code> header file.</p> <p><code>rt_globpri</code> The global scheduling priority associated with this priority level. The <code>rt_globpri</code> values cannot be changed with <code>dispadmin(1M)</code>.</p> <p><code>rt_quantum</code> The length of the time quantum allocated to processes at this level in ticks (Hz). The time quantum value is only a default or starting value for processes at a particular level as the time quantum of a real-time process can be changed by the user with the <code>priocntl</code> command or the <code>priocntl</code> system call.</p> <p>An administrator can affect the behavior of the real-time portion of the scheduler by reconfiguring the <code>rt_dptbl</code>. There are two methods available for doing this: reconfigure with a loadable module at boot-time or by using <code>dispadmin(1M)</code> at run-time.</p> <p>rt_dptbl Loadable Module</p> <p>The <code>rt_dptbl</code> can be reconfigured with a loadable module which contains a new real time dispatch table. The module containing the dispatch table is separate from the RT loadable module which contains the rest of the real time software. This is the only method that can be used to change the number of real time priority levels or the set of global scheduling priorities used by the real time class. The relevant procedure and source code is described in the EXAMPLES section.</p>

rt_dptbl(4)

dispadmin Configuration File

The `rt_quantum` values in the `rt_dptbl` can be examined and modified on a running system using the `dispadmin(1M)` command. Invoking `dispadmin` for the real-time class allows the administrator to retrieve the current `rt_dptbl` configuration from the kernel's in-core table, or overwrite the in-core table with values from a configuration file. The configuration file used for input to `dispadmin` must conform to the specific format described below.

Blank lines are ignored and any part of a line to the right of a `#` symbol is treated as a comment. The first non-blank, non-comment line must indicate the resolution to be used for interpreting the time quantum values. The resolution is specified as

```
RES=res
```

where *res* is a positive integer between 1 and 1,000,000,000 inclusive and the resolution used is the reciprocal of *res* in seconds. (For example, `RES=1000` specifies millisecond resolution.) Although very fine (nanosecond) resolution may be specified, the time quantum lengths are rounded up to the next integral multiple of the system clock's resolution.

The remaining lines in the file are used to specify the `rt_quantum` values for each of the real-time priority levels. The first line specifies the quantum for real-time level 0, the second line specifies the quantum for real-time level 1. There must be exactly one line for each configured real-time priority level. Each `rt_quantum` entry must be either a positive integer specifying the desired time quantum (in the resolution given by *res*), or the value -2 indicating an infinite time quantum for that level.

EXAMPLES

EXAMPLE 1 A Sample `dispadmin` Configuration File

The following excerpt from a `dispadmin` configuration file illustrates the format. Note that for each line specifying a time quantum there is a comment indicating the corresponding priority level. These level numbers indicate priority within the real-time class, and the mapping between these real-time priorities and the corresponding global scheduling priorities is determined by the configuration specified in the `RT_DPTBL` loadable module. The level numbers are strictly for the convenience of the administrator reading the file and, as with any comment, they are ignored by `dispadmin` on input. `dispadmin` assumes that the lines in the file are ordered by consecutive, increasing priority level (from 0 to the maximum configured real-time priority). The level numbers in the comments should normally agree with this ordering; if for some reason they don't, however, `dispadmin` is unaffected.

```
# Real-Time Dispatcher Configuration File
RES=1000

# TIME QUANTUM PRIORITY
# (rt_quantum) LEVEL
100# 0
100# 1
100# 2
100# 3
100# 4
100# 5
```

.. .
10# 58
10# 59

```

EXAMPLE 2 Replacing The rt_dptbl Loadable Module

In order to change the size of the real time dispatch table, the loadable module which contains the dispatch table information will have to be built. It is recommended that you save the existing module before using the following procedure.

1. Place the dispatch table code shown below in a file called `rt_dptbl.c`. An example of an `rt_dptbl.c` file follows.
2. Compile the code using the given compilation and link lines supplied.

```

cc -c -O -D_KERNEL rt_dptbl.c
ld -r -o RT_DPTBL rt_dptbl.o

```

3. Copy the current dispatch table in `/usr/kernel/sched` to `RT_DPTBL.bak`.
4. Replace the current `RT_DPTBL` in `/usr/kernel/sched`.
5. You will have to make changes in the `/etc/system` file to reflect the changes to the sizes of the tables. See `system(4)`. The `rt_maxpri` variable may need changing. The syntax for setting this is:

```

set RT:rt_maxpri=(class-specific value for maximum real-time priority)

```

6. Reboot the system to use the new dispatch table.

Great care should be used in replacing the dispatch table using this method. If you don't get it right, the system may not behave properly.

The following is an example of a `rt_dptbl.c` file used for building the new `rt_dptbl`.

```

/* BEGIN rt_dptbl.c */
#include <sys/proc.h>
#include <sys/priocntl.h>
#include <sys/class.h>
#include <sys/disp.h>
#include <sys/rt.h>
#include <sys/rtpriocntl.h>
/*
 * This is the loadable module wrapper.
 */
#include <sys/modctl.h>
extern struct mod_ops mod_miscops;
/*
 * Module linkage information for the kernel.

```

rt_dptbl(4)

System Administration Guide: Basic Administration

Programming Interfaces Guide

sbus(4)

NAME	sbus – configuration files for SBus device drivers
DESCRIPTION	<p>The SBus is a geographically addressed peripheral bus present on many SPARC hardware platforms. SBus devices are <i>self-identifying</i> — that is to say the SBus card itself provides information to the system so that it can identify the device driver that needs to be used. The device usually provides additional information to the system in the form of name-value pairs that can be retrieved using the DDI property interfaces. See <code>ddi_prop_op(9F)</code> for details.</p> <p>The information is usually derived from a small Forth program stored in the FCode PROM on the card, so driver configuration files should be completely unnecessary for these devices. However, on some occasions, drivers for SBus devices may need to use driver configuration files to augment the information provided by the SBus card. See <code>driver.conf(4)</code> for further details.</p> <p>When they are needed, configuration files for SBus device drivers should identify the parent bus driver implicitly using the <i>class</i> keyword. This removes the dependency on the particular bus driver involved since this may be named differently on different platforms.</p> <p>All bus drivers of class <code>sbus</code> recognise the following properties:</p> <p>reg An arbitrary length array where each element of the array consists of a 3-tuple of integers. Each array element describes a logically contiguous mappable resource on the SBus.</p> <p> The first integer of each tuple specifies the slot number the card is plugged into. The second integer of each 3-tuple specifies the offset in the slot address space identified by the first element. The third integer of each 3-tuple specifies the size in bytes of the mappable resource.</p> <p> The driver can refer to the elements of this array by index, and construct kernel mappings to these addresses using <code>ddi_map_regs(9F)</code>. The index into the array is passed as the <i>rnumber</i> argument of <code>ddi_map_regs()</code>.</p> <p> You can use the <code>ddi_get*</code> and <code>ddi_put*</code> family of functions to access register space from a high-level interrupt context.</p> <p>interrupts An arbitrary length array where each element of the array consists of a single integer. Each array element describes a possible SBus interrupt level that the device might generate.</p> <p> The driver can refer to the elements of this array by index, and register interrupt handlers with the system using <code>ddi_add_intr(9F)</code>. The index into the array is passed as the <i>inumber</i> argument of <code>ddi_add_intr()</code>.</p>

`registers` An arbitrary length array where each element of the array consists of a 3-tuple of integers. Each array element describes a logically contiguous mappable resource on the SBus.

The first integer of each tuple should be set to `-1`, specifying that any SBus slot may be matched. The second integer of each 3-tuple specifies the offset in the slot address space identified by the first element. The third integer of each 3-tuple specifies the size in bytes of the mappable resource.

The `registers` property can only be used to augment an incompletely specified `reg` property with information from a driver configuration file. It may only be specified in a driver configuration file.

All SBus devices must provide `reg` properties to the system. The first two integer elements of the `reg` property are used to construct the address part of the device name under `/devices`.

Only devices that generate interrupts need to provide `interrupts` properties.

Occasionally, it may be necessary to override or augment the configuration information supplied by the SBus device. This can be achieved by writing a driver configuration file that describes a prototype device information (`devinfo`) node specification, containing the additional properties required.

For the system to merge the information, certain conditions must be met. First, the name property must be the same. Second, either the first two integers (slot number and offset) of the two `reg` properties must be the same, or the second integer (offset) of the `reg` and `registers` properties must be the same.

In the event that the SBus card has no `reg` property at all, the self-identifying information cannot be used, so all the details of the card must be specified in a driver configuration file.

EXAMPLES **EXAMPLE 1** A sample configuration file.

Here is a configuration file for an SBus card called `SUNW,netboard`. The card already has a simple FCode PROM that creates name and `reg` properties, and will have a complete set of properties for normal use once the driver and firmware is complete.

In this example, we want to augment the properties given to us by the firmware. We use the same name property, and use the `registers` property to match the firmware `reg` property. That way we don't have to worry about which slot the card is really plugged into.

We want to add an `interrupts` property while we are developing the firmware and driver so that we can start to experiment with interrupts. The device can generate interrupts at SBus level 3. Additionally, we want to set a `debug-level` property to 4.

Writing Device Drivers

WARNINGS The wildcarding mechanism of the `registers` property matches every instance of the particular device attached to the system. This may not always be what is wanted.

NAME	sccsfile – format of an SCCS history file
DESCRIPTION	<p>An SCCS file is an ASCII file consisting of six logical parts:</p> <p><i>checksum</i> character count used for error detection</p> <p><i>delta table</i> log containing version info and statistics about each delta</p> <p><i>usernames</i> login names and/or group IDs of users who may add deltas</p> <p><i>flags</i> definitions of internal keywords</p> <p><i>comments</i> arbitrary descriptive information about the file</p> <p><i>body</i> the actual text lines intermixed with control lines</p> <p>Each section is described in detail below.</p>
Conventions	<p>Throughout an SCCS file there are lines which begin with the ASCII SOH (start of heading) character (octal 001). This character is hereafter referred to as the <i>control character</i>, and will be represented as '^A'. If a line described below is not depicted as beginning with the control character, it cannot do so and still be within SCCS file format.</p> <p>Entries of the form <i>dddd</i> represent a five digit string (a number between 00000 and 99999).</p>
Checksum	<p>The checksum is the first line of an SCCS file. The form of the line is:</p> <p><i>^A hdddd</i></p> <p>The value of the checksum is the sum of all characters, except those contained in the first line. The <i>^Ah</i> provides a <i>magic number</i> of (octal) 064001.</p>
Delta Table	<p>The delta table consists of a variable number of entries of the form:</p> <p><i>^As inserted /deleted /unchanged</i></p> <p><i>^Ad type sid yr /mo /da hr :mi :se username serial-number predecessor-sn</i></p> <p><i>^Ai include-list</i></p> <p><i>^Ax exclude-list</i></p> <p><i>^Ag ignored-list</i></p> <p><i>^Am nr-number</i></p> <p>. . .</p> <p><i>^Ac comments . . .</i></p> <p>. . .</p> <p><i>^Ae</i> The first line (<i>^As</i>) contains the number of lines inserted/deleted/unchanged</p>

sccsfile(4)

respectively. The second line (^Ad) contains the type of the delta (normal: D, and removed: R), the SCCS ID of the delta, the date and time of creation of the delta, the user-name corresponding to the real user ID at the time the delta was created, and the serial numbers of the delta and its predecessor, respectively. The ^Ai, ^Ax, and ^Ag lines contain the serial numbers of deltas included, excluded, and ignored, respectively. These lines do not always appear.

The ^Am lines (optional) each contain one MR number associated with the delta; the ^Ac lines contain comments associated with the delta.

The ^Ae line ends the delta table entry.

User Names The list of user-names and/or numerical group IDs of users who may add deltas to the file, separated by NEWLINE characters. The lines containing these login names and/or numerical group IDs are surrounded by the bracketing lines ^Au and ^AU. An empty list allows anyone to make a delta.

Flags Flags are keywords that are used internally (see `sccs-admin(1)` for more information on their use). Each flag line takes the form:

^Af flag

optional text The following flags are defined in order of appearance:

^Af t type-of-program

Defines the replacement for the 17:21:50 ID keyword.

^Af v program-name

Controls prompting for MR numbers in addition to comments; if the optional text is present it defines an MR number validity checking program.

^Af i

Indicates that the 'No id keywords' message is to generate an error that terminates the SCCS command. Otherwise, the message is treated as a warning only.

^Af b

Indicates that the -b option may be used with the SCCS get command to create a branch in the delta tree.

^Af m module name

Defines the first choice for the replacement text of the `sccsfile.4` ID keyword.

^Af f floor

Defines the "floor" release; the release below which no deltas may be added.

^Af c ceiling

Defines the "ceiling" release; the release above which no deltas may be added.

^A f d *default-sid*

The *d* flag defines the default SID to be used when none is specified on an SCCS *get* command.

^A f n

The *n* flag enables the SCCS *delta* command to insert a “null” delta (a delta that applies *no* changes) in those releases that are skipped when a delta is made in a *new* release (for example, when delta 5.1 is made after delta 2.7, releases 3 and 4 are skipped).

^A f j

Enables the SCCS *get* command to allow concurrent edits of the same base SID.

^A f l *lock-releases*

Defines a *list* of releases that are locked against editing.

^A f q *user defined*

Defines the replacement for the ID keyword.

^A f e *0|1*

The *e* flag indicates whether a source file is encoded or not. A *1* indicates that the file is encoded. Source files need to be encoded when they contain control characters, or when they do not end with a NEWLINE. The *e* flag allows files that contain binary data to be checked in.

Comments Arbitrary text surrounded by the bracketing lines **^A t** and **^A T**. The comments section typically will contain a description of the file’s purpose.

Body The body consists of text lines and control lines. Text lines do not begin with the control character, control lines do. There are three kinds of control lines: *insert*, *delete*, and *end*, represented by:

^A I *dddd*

^A D *dddd*

^A E *dddd*

respectively. The digit string is the serial number corresponding to the delta for the control line.

scsi(4)

NAME	scsi – configuration files for SCSI target drivers				
DESCRIPTION	<p>The architecture of the Solaris SCSI subsystem distinguishes two types of device drivers: SCSI target drivers, and SCSI host adapter drivers. Target drivers like <code>sd(7D)</code> and <code>st(7D)</code> manage the device on the other end of the SCSI bus. Host adapter drivers manage the SCSI bus on behalf of all the devices that share it.</p> <p>Drivers for host adapters provide a common set of interfaces for target drivers. These interfaces comprise the Sun Common SCSI Architecture (SCSA) which are documented as part of the Solaris DDI/DKI. See <code>scsi_ifgetcap(9F)</code>, <code>scsi_init_pkt(9F)</code>, and <code>scsi_transport(9F)</code> for further details of these, and associated routines.</p> <p>Target drivers for SCSI devices should use a driver configuration file to enable them to be recognized by the system.</p> <p>Configuration files for SCSI target drivers should identify the host adapter driver implicitly using the <code>class</code> keyword to remove any dependency on the particular host adapter involved.</p> <p>All host adapter drivers of class <code>scsi</code> recognize the following properties:</p> <table><tr><td><code>target</code></td><td>Integer-valued SCSI target identifier that this driver will claim.</td></tr><tr><td><code>lun</code></td><td>Integer-valued SCSI logical unit number (LUN) that this driver will claim.</td></tr></table> <p>All SCSI target drivers must provide <code>target</code> and <code>lun</code> properties. These properties are used to construct the address part of the device name under <code>/devices</code>.</p> <p>The SCSI target driver configuration files shipped with Solaris have entries for LUN 0 only. For devices that support other LUNs, such as some CD changers, the system administrator may edit the driver configuration file to add entries for other LUNs.</p>	<code>target</code>	Integer-valued SCSI target identifier that this driver will claim.	<code>lun</code>	Integer-valued SCSI logical unit number (LUN) that this driver will claim.
<code>target</code>	Integer-valued SCSI target identifier that this driver will claim.				
<code>lun</code>	Integer-valued SCSI logical unit number (LUN) that this driver will claim.				
EXAMPLES	<p>EXAMPLE 1 A sample configuration file.</p> <p>Here is a configuration file for a SCSI target driver called <code>toaster.conf</code>.</p> <pre># # Copyright (c) 1992, by Sun Microsystems, Inc. # #ident "@(#)toaster.conf 1.2 92/05/12 SMI" name="toaster" class="scsi" target=4 lun=0;</pre> <p>Add the following lines to <code>sd.conf</code> for a six- CD changer on target 3, with LUNs 0 to 5.</p> <pre>name="sd" class="scsi" target=3 lun=1; name="sd" class="scsi" target=3 lun=2; name="sd" class="scsi" target=3 lun=3; name="sd" class="scsi" target=3 lun=4; name="sd" class="scsi" target=3 lun=5;</pre>				

EXAMPLE 1 A sample configuration file. *(Continued)*

It is not necessary to add the line for LUN 0, as it already exists in the file shipped with Solaris.

`scsi_transport(9F)`

Writing Device Drivers

ANSI Small Computer System Interface-2 (SCSI-2)

NOTES You need to ensure that the `target` and `lun` values claimed by your target driver do not conflict with existing target drivers on the system. For example, if the target is a direct access device, the standard `sd.conf` file will usually make `sd` claim it before any other driver has a chance to probe it.

securenets(4)

NAME	securenets – configuration file for NIS security
SYNOPSIS	<code>/var/yp/securenets</code>
DESCRIPTION	<p>The <code>/var/yp/securenets</code> file defines the networks or hosts which are allowed access to information by the Network Information Service (“NIS”).</p> <p>The format of the file is as follows:</p> <ul style="list-style-type: none">■ Lines beginning with the “#” character are treated as comments.■ Otherwise, each line contains two fields separated by white space. The first field is a netmask, the second a network.■ The netmask field may be either <code>255.255.255.255</code> (IPv4), <code>ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff</code> (IPv6), or the string “host” indicating that the second field is a specific host to be allowed access. <p>Both <code>ypserv(1M)</code> and <code>ypxfrd(1M)</code> use the <code>/var/yp/securenets</code> file. The file is read when the <code>ypserv(1M)</code> and <code>ypxfrd(1M)</code> daemons begin. If <code>/var/yp/securenets</code> is present, <code>ypserv(1M)</code> and <code>ypxfrd(1M)</code> respond only to IP addresses in the range given. In order for a change in the <code>/var/yp/securenets</code> file to take effect, you must kill and restart any active daemons using <code>ypstop(1M)</code> and <code>ypstart(1M)</code>.</p> <p>An important thing to note for all the examples below is that the server must be allowed to access itself. You accomplish this either by the server being part of a subnet that is allowed to access the server, or by adding an individual entry, as the following:</p> <pre>hosts 127.0.0.1</pre>
EXAMPLES	<p>EXAMPLE 1 Access for Individual Entries</p> <p>If individual machines are to be give access, the entry could be:</p> <pre>255.255.255.255 192.9.1.20 or host 192.0.1.20</pre> <p>EXAMPLE 2 Access for a Class C Network</p> <p>If access is to be given to an entire class C network, the entry could be:</p> <pre>255.255.255.0 192.9.1.0</pre> <p>EXAMPLE 3 Access for a Class B Network</p> <p>The entry for access to a class B network could be:</p> <pre>255.255.0.0 9.9.0.0</pre>

EXAMPLE 3 Access for a Class B Network *(Continued)*

EXAMPLE 4 Access for an Individual IPv6 Address

Similarly, to allow access for an individual IPv6 address:

```
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff fec0::111:abba:ace0:fba5e:1
```

Or

```
host fec0::111:abba:ace0:fba5e:1
```

EXAMPLE 5 Access for all IPv6 Addresses Starting with fe80

To allow access for all IPv6 addresses starting with fe80:

```
ffff:: fe80::
```

FILES /var/yp/securenets Configuration file for NIS security.

SEE ALSO ypserv(1M), ypstart(1M), ypstop(1M), ypxfrd(1M)

NOTES The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

services(4)

NAME	services – Internet services and aliases
SYNOPSIS	<code>/etc/inet/services</code> <code>/etc/services</code>
DESCRIPTION	<p>The <code>services</code> file is a local source of information regarding each service available through the Internet. The <code>services</code> file can be used in conjunction with or instead of other services sources, including the NIS maps “<code>services.byname</code>” and the NIS+ table “<code>services</code>.” Programs use the <code>getservbyname(3SOCKET)</code> routines to access this information.</p> <p>The <code>services</code> file contains an entry for each service. Each entry has the form:</p> <pre><i>service-name</i> <i>port/protocol</i> <i>aliases</i></pre> <p><i>service-name</i> This is the official Internet service name.</p> <p><i>port/protocol</i> This field is composed of the port number and protocol through which the service is provided, for instance, <code>512/tcp</code>.</p> <p><i>aliases</i> This is a list of alternate names by which the service might be requested.</p> <p>Fields can be separated by any number of SPACE and/or TAB characters. A number sign (#) indicates the beginning of a comment; any characters that follow the comment character up to the end of the line are not interpreted by routines which search the file.</p> <p>Service names may contain any printable character other than a field delimiter, a NEWLINE, or a comment character.</p> <p>Any changes to a port assignment do not affect the actual port registration of the service.</p>
FILES	<code>/etc/nsswitch.conf</code> configuration file for name-service switch
SEE ALSO	<code>getservbyname(3SOCKET)</code> , <code>inetd.conf(4)</code> , <code>nsswitch.conf(4)</code>
NOTES	<code>/etc/inet/services</code> is the official SVR4 name of the <code>services</code> file. The symbolic link <code>/etc/services</code> exists for BSD compatibility.

NAME	shadow – shadow password file																		
DESCRIPTION	<p><code>/etc/shadow</code> is an access-restricted ASCII system file that stores users' encrypted passwords and related information. The shadow file can be used in conjunction with other shadow sources, including the NIS maps <code>passwd.byname</code> and <code>passwd.byuid</code> and the NIS+ table <code>passwd</code>. Programs use the <code>getspnam(3C)</code> routines to access this information.</p> <p>The fields for each user entry are separated by colons. Each user is separated from the next by a newline. Unlike the <code>/etc/passwd</code> file, <code>/etc/shadow</code> does not have general read permission.</p> <p>Each entry in the shadow file has the form:</p> <p><code>username:password:lastchg:min:max:warn:inactive:expire:flag</code> The fields are defined as follows:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>username</i></td> <td>The user's login name (UID).</td> </tr> <tr> <td><i>password</i></td> <td>A 13-character encrypted password for the user, a <i>lock</i> string to indicate that the login is not accessible, or no string, which shows that there is no password for the login.</td> </tr> <tr> <td><i>lastchg</i></td> <td>The number of days between January 1, 1970, and the date that the password was last modified.</td> </tr> <tr> <td><i>min</i></td> <td>The minimum number of days required between password changes.</td> </tr> <tr> <td><i>max</i></td> <td>The maximum number of days the password is valid.</td> </tr> <tr> <td><i>warn</i></td> <td>The number of days before password expires that the user is warned.</td> </tr> <tr> <td><i>inactive</i></td> <td>The number of days of inactivity allowed for that user.</td> </tr> <tr> <td><i>expire</i></td> <td>An absolute date specifying when the login may no longer be used.</td> </tr> <tr> <td><i>flag</i></td> <td>Reserved for future use, set to zero. Currently not used.</td> </tr> </table> <p>The encrypted password consists of 13 characters chosen from a 64-character alphabet (<code>./, 0-9, A-Z, a-z</code>). To update this file, use the <code>passwd(1)</code>, <code>useradd(1M)</code>, <code>usermod(1M)</code>, or <code>userdel(1M)</code> commands.</p> <p>In order to make system administration manageable, <code>/etc/shadow</code> entries should appear in exactly the same order as <code>/etc/passwd</code> entries; this includes "+" and "-" entries if the <code>compat</code> source is being used (see <code>nsswitch.conf(4)</code>).</p>	<i>username</i>	The user's login name (UID).	<i>password</i>	A 13-character encrypted password for the user, a <i>lock</i> string to indicate that the login is not accessible, or no string, which shows that there is no password for the login.	<i>lastchg</i>	The number of days between January 1, 1970, and the date that the password was last modified.	<i>min</i>	The minimum number of days required between password changes.	<i>max</i>	The maximum number of days the password is valid.	<i>warn</i>	The number of days before password expires that the user is warned.	<i>inactive</i>	The number of days of inactivity allowed for that user.	<i>expire</i>	An absolute date specifying when the login may no longer be used.	<i>flag</i>	Reserved for future use, set to zero. Currently not used.
<i>username</i>	The user's login name (UID).																		
<i>password</i>	A 13-character encrypted password for the user, a <i>lock</i> string to indicate that the login is not accessible, or no string, which shows that there is no password for the login.																		
<i>lastchg</i>	The number of days between January 1, 1970, and the date that the password was last modified.																		
<i>min</i>	The minimum number of days required between password changes.																		
<i>max</i>	The maximum number of days the password is valid.																		
<i>warn</i>	The number of days before password expires that the user is warned.																		
<i>inactive</i>	The number of days of inactivity allowed for that user.																		
<i>expire</i>	An absolute date specifying when the login may no longer be used.																		
<i>flag</i>	Reserved for future use, set to zero. Currently not used.

SEE ALSO login(1), passwd(1), useradd(1M), userdel(1M), usermod(1M), getspnam(3C), putspent(3C), nsswitch.conf(4), passwd(4)

NOTES If password aging is turned on in any name service the *passwd:* line in the `/etc/nsswitch.conf` file must have a format specified in the `nsswitch.conf(4)` man page.

If the `/etc/nsswitch.conf` `passwd` policy is not in one of the supported formats, logins will not be allowed upon password expiration because the software does not know how to handle password updates under these conditions. See `nsswitch.conf(4)` for additional information.

NAME	sharetab – shared file system table										
DESCRIPTION	<p>sharetab resides in directory <code>/etc/dfs</code> and contains a table of local resources shared by the <code>share</code> command.</p> <p>Each line of the file consists of the following fields:</p> <p><i>pathname resource fstype specific_options description</i></p> <p>where</p> <table> <tr> <td><i>pathname</i></td> <td>Indicate the path name of the shared resource.</td> </tr> <tr> <td><i>resource</i></td> <td>Indicate the symbolic name by which remote systems can access the resource.</td> </tr> <tr> <td><i>fstype</i></td> <td>Indicate the file system type of the shared resource.</td> </tr> <tr> <td><i>specific_options</i></td> <td>Indicate file-system-type-specific options that were given to the <code>share</code> command when the resource was shared.</td> </tr> <tr> <td><i>description</i></td> <td>Describe the shared resource provided by the system administrator when the resource was shared.</td> </tr> </table>	<i>pathname</i>	Indicate the path name of the shared resource.	<i>resource</i>	Indicate the symbolic name by which remote systems can access the resource.	<i>fstype</i>	Indicate the file system type of the shared resource.	<i>specific_options</i>	Indicate file-system-type-specific options that were given to the <code>share</code> command when the resource was shared.	<i>description</i>	Describe the shared resource provided by the system administrator when the resource was shared.
<i>pathname</i>	Indicate the path name of the shared resource.										
<i>resource</i>	Indicate the symbolic name by which remote systems can access the resource.										
<i>fstype</i>	Indicate the file system type of the shared resource.										
<i>specific_options</i>	Indicate file-system-type-specific options that were given to the <code>share</code> command when the resource was shared.										
<i>description</i>	Describe the shared resource provided by the system administrator when the resource was shared.										
SEE ALSO	share(1M)										

shells(4)

NAME	shells – shell database
SYNOPSIS	/etc/shells
DESCRIPTION	<p>The <code>shells</code> file contains a list of the shells on the system. Applications use this file to determine whether a shell is valid. See <code>getusershell(3C)</code>. For each shell a single line should be present, consisting of the shell's path, relative to root.</p> <p>A hash mark (#) indicates the beginning of a comment; subsequent characters up to the end of the line are not interpreted by the routines which search the file. Blank lines are also ignored.</p> <p>The following default shells are used by utilities: <code>/bin/bash</code>, <code>/bin/csh</code>, <code>/bin/jsh</code>, <code>/bin/ksh</code>, <code>/bin/pfcsh</code>, <code>/bin/pfksh</code>, <code>/bin/pfsh</code>, <code>/bin/sh</code>, <code>/bin/tcsh</code>, <code>/bin/zsh</code>, <code>/sbin/jsh</code>, <code>/sbin/sh</code>, <code>/usr/bin/bash</code>, <code>/usr/bin/csh</code>, <code>/usr/bin/jsh</code>, <code>/usr/bin/ksh</code>, <code>/usr/bin/pfcsh</code>, <code>/usr/bin/pfksh</code>, <code>/usr/bin/pfsh</code>, and <code>/usr/bin/sh</code>, <code>/usr/bin/tcsh</code>, <code>/usr/bin/zsh</code>. Note that <code>/etc/shells</code> overrides the default list.</p> <p>Invalid shells in <code>/etc/shells</code> may cause unexpected behavior (such as being unable to log in by way of <code>ftp(1)</code>).</p>
FILES	<code>/etc/shells</code> lists shells on system

NAME	slp.conf – configuration file for Service Location Protocol agents
SYNOPSIS	/etc/inet/slp.conf
DESCRIPTION	<p>slp.conf provides all Service Location Protocol (“SLP”) agents with their operational configuration. slpd(1M) reads slp.conf on startup. Service Agents (“SAs”) and User Agents (“UAs”) read slp.conf on invocation of the SA and UA library routines; configuration parameters are then cached on a per-process basis. All SA’s must use the same set of properties as slpd on the local machine, since slpd acts as an SA server.</p> <p>The configuration file format consists of a newline-delimited list of zero or more property definitions. Each property definition corresponds to a particular configurable SLP, network, or other parameter in one or more of the three SLP agents. The file format grammar is shown in <i>RFC 2234</i> as follows:</p> <pre> config-file = line-list line-list = line / line line-list line = property-line / comment-line comment-line = ("#" / ";") 1*allchar newline property-line = property newline property = tag "=" value-list tag = prop / prop "." tag prop = 1*tagchar value-list = value / value "," value-list value = int / bool / "(" value-list ")" / string int = 1*DIGIT bool = "true" / "false" / "TRUE" / "FALSE" newline = CR / (CRLF) string = 1*stringchar tagchar = DIGIT / ALPHA / tother / escape tother = %x21-%x2d / %x2f / %x3a / %x3c-%x40 / %x5b-%x60 / %7b-%7e ; i.e., all characters except `.', ; and `=' . stringchar = DIGIT / ALPHA / sother / escape sother = %x21-%x29 / %x2a-%x2b / %x2d-%x2f / %x3a-%x40 / %x5b-%x60 / %7b-%7e ; i.e., all characters except `,' allchar = DIGIT / ALPHA / HTAB / SP escape = "\" HEXDIG HEXDIG ; Used for reserved characters </pre> <p>The properties fall into one of the following categories:</p> <ul style="list-style-type: none"> ■ DA Configuration ■ Static Scope Configuration ■ Tracing and Logging ■ Serialized Proxy Registrations ■ Networking Configuration Parameters

slp.conf(4)

DA Configuration

■ UA Configuration

The following are configuration properties and their parameters for DAs:

`net.slp.isDA`

Setting Type Boolean

Default Value False

Range of Values True or False A boolean that indicates whether `slpd(1M)` is to act as a DA. If `False`, `slpd(1M)` is not run as a DA.

`net.slp.DAHeartBeat`

Setting Type Integer

Default Value 10800 seconds (3 hours)

Range of Values 2000 – 259200000 seconds A 32-bit integer giving the number of seconds for the passive DA advertisement heartbeat. The default value is 10800 seconds. This property is ignored if `net.slp.isDA` is `False`.

`net.slp.DAAttributes`

Setting Type List of Strings

Default Value Unassigned

Range of Values List of Attribute Tag/Value List Pairs

A comma-separated list of parenthesized attribute tag/value list pairs that the DA must advertise in DA advertisements. The property must be in the SLP attribute list wire format, which requires that you use a backslash (“\”) to escape reserved characters. See *RFC 2608* for more information on reserved characters, or refer to the *System Administration Guide: Resource Management and Network Services*.

Static Scope Configuration

The following properties and their parameters allow you to configure various aspects of scope and DA handling:

`net.slp.useScopes`

Setting Type List of Strings

Default Value Default, for SA and DA; unassigned for UA.

Range of Values List of Strings A list of strings indicating either the scopes that a UA or an SA is allowed to use when making requests, or the scopes a DA must support. If not present for the DA and SA, the default scope `Default` is used. If not present for the UA, then the user scoping model is in force, in which active and passive DA or SA discovery are used for scope discovery. The scope `Default` is used if no other information is available. If a DA or SA gets another scope in a request, a `SCOPE_NOT_SUPPORTED` error is returned, unless the request was multicast, in which case it is dropped. If a DA receives another scope in a registration, a `SCOPE_NOT_SUPPORTED` error will be returned. Unlike other properties, this property

is "read-only", so attempts to change it programmatically after the configuration file has been read are ignored.

`net.slp.DAAddresses`

Setting Type	List of Strings
Default Value	Unassigned
Range of Values	IPv4 addresses or host names

A list of IP addresses or DNS-resolvable names that denote the DAs to use for statically configured UAs and SAs. The property is read by `slpd(1M)`, and registrations are forwarded to the DAs. The DAs are provided to UAs upon request. Unlike other properties, this property is "read-only", so attempts to change it after the configuration file has been read are ignored.

The following grammar describes the property:

```
addr-list = addr / addr "," addr-list
addr      = fqdn / hostnumber
fqdn     = ALPHA / ALPHA *["-" ] anum
anum     = ALPHA / DIGIT
hostnumber = 1*3DIGIT 3("." 1*3DIGIT)
```

The following is an example using this grammar:

```
sawah,mandi,samba
```

IP addresses can be used instead of host names in networks where DNS is not deployed, but network administrators are reminded that using IP addresses will complicate machine renumbering, since the SLP configuration property files in statically configured networks will have to be changed.

Tracing and Logging

These properties direct tracing and logging information to be sent to `syslogd` at the `LOG_INFO` priority. These properties affect `slpd(1M)` only.

`net.slp.traceDATraffic`

Setting Type	Boolean
Default Value	False
Range of Values	True or False

Set `net.slp.traceDATraffic` to `True` to enable logging of DA traffic by `slpd`.

`net.slp.traceMsg`

Setting Type	Boolean
Default Value	False
Range of Values	True or False

Set `net.slp.traceMsg` to `True` to display details about SLP messages. The fields in all incoming messages and outgoing replies are printed by `slpd`.

slp.conf(4)

`net.slp.traceDrop`

Setting Type	Boolean
Default Value	False
Range of Values	True or False

Set this property to True to display details when an SLPmessage is dropped by `slpd` for any reason.

`net.slp.traceReg`

Setting Type	Boolean
Default Value	False
Range of Values	True or False

Set this property to True to display the table of service advertisements when a registration or deregistration is processed by `slpd`.

Serialized Proxy Registrations

The following properties control reading and writing serialized registrations.

`net.slp.serializedRegURL`

Setting Type	String
Default Value	Unassigned
Range of Values	Valid URL

A string containing a URL pointing to a document, which contains serialized registrations that should be processed when the `slpd` starts up.

Networking Configuration Parameters

The properties that follow allow you to set various network configuration parameters:

`net.slp.isBroadcastOnly`

Setting Type	Boolean
Default Value	False
Range of Values	True or False

A boolean that indicates if broadcast should be used instead of multicast.

`net.slp.multicastTTL`

Setting Type	Positive Integer
Default Value	255
Range of Values	A positive integer from 1 to 255.

A positive integer less than or equal to 255 that defines the multicast TTL.

```
net.slp.DAActiveDiscoveryInterval
```

Setting Type	Integer
Default Value	900 seconds (15 minutes)
Range of Values	From 300 to 10800 seconds

A 16-bit positive integer giving the number of seconds between DA active discovery queries. The default value is 900 seconds (15 minutes). If the property is set to zero, active discovery is turned off. This is useful when the DAs available are explicitly restricted to those obtained from the `net.slp.DAAddresses` property.

```
net.slp.multicastMaximumWait
```

Setting Type	Integer
Default Value	15000 milliseconds (15 seconds)
Range of Values	1000 to 60000 milliseconds

A 32-bit integer giving the maximum value for the sum of the `net.slp.multicastTimeouts` values and `net.slp.DADiscoveryTimeouts` values in milliseconds.

```
net.slp.multicastTimeouts
```

Setting Type	List of Integers
Default Value	3000, 3000, 3000, 3000
Range of Values	List of Positive Integers

A list of 32-bit integers used as timeouts, in milliseconds, to implement the multicast convergence algorithm. Each value specifies the time to wait before sending the next request, or until nothing new has been learned from two successive requests. In a fast network the aggressive values of 1000, 1250, 1500, 2000, 4000 allow better performance. The sum of the list must equal `net.slp.multicastMaximumWait`.

```
net.slp.passiveDADetection
```

Setting Type	Boolean
Default Value	True
Range of Values	True or False

A boolean indicating whether `slpd` should perform passive DA detection.

```
net.slp.DADiscoveryTimeouts
```

Setting Type	List of Integers.
Default Value	2000, 2000, 2000, 2000, 3000, 4000
Range of Values	List of Positive Integers

slp.conf(4)

A list of 32-bit integers used as timeouts, in milliseconds, to implement the multicast convergence algorithm during active DA discovery. Each value specifies the time to wait before sending the next request, or until nothing new has been learned from two successive requests. The sum of the list must equal `net.slp.multicastMaximumWait`.

`net.slp.datagramTimeouts`

Setting Type	List of Integers
Default Value	3000, 3000, 3000
Range of Values	List of Positive Integers

A list of 32-bit integers used as timeouts, in milliseconds, to implement unicast datagram transmission to DAs. The n th value gives the time to block waiting for a reply on the n th try to contact the DA.

`net.slp.randomWaitBound`

Setting Type	Integer
Default Value	1000 milliseconds (1 second)
Range of Values	1000 to 3000 milliseconds

Sets the upper bound for calculating the random wait time before attempting to contact a DA.

`net.slp.MTU`

Setting Type	Integer
Default Value	1400
Range of Values	128 to 8192

A 16-bit integer that specifies the network packet size, in bytes. The packet size includes IP and TCP or UDP headers.

`net.slp.interfaces`

Setting Type	List of Strings
Default Value	Default interface
Range of Values	IPv4 addresses or host names

List of strings giving the IP addresses or host names of the network interface cards on which the DA or SA should listen on port 427 for multicast, unicast UDP, and TCP messages. The default value is unassigned, indicating that the default network interface card should be used. An example is:

`195.42.42.42, 195.42.142.1, 195.42.120.1` The example machine has three interfaces on which the DA should listen. Note that if IP addresses are used, the property must be renumbered if the network is renumbered.

UA Configuration

The following configuration parameters apply to the UA:

`net.slp.locale`

Setting Type String

Default Value en

Range of Values See *RFC 1766* for a list of the locale language tag names.

A *RFC 1766* Language Tag for the language locale. Setting this property causes the property value to become the default locale for SLP messages.

`net.slp.maxResults`

Setting Type Integer

Default Value -1

Range of Values -1, positive integer

A 32 bit-integer that specifies the maximum number of results to accumulate and return for a synchronous request before the timeout, or the maximum number of results to return through a callback if the request results are reported asynchronously. Positive integers and -1 are legal values. If the value of `net.slp.maxResults` is -1, all results should be returned.

`net.slp.typeHint`

Setting Type List of Strings

Default Value Unassigned

Range of Values Service type names

A list of service type names. In the absence of any DAs, UAs perform SA discovery to find scopes. If the `net.slp.typeHint` property is set, only SA's advertising types on the list respond. Note that UAs set this property programmatically. It is not typically set in the configuration file. The default is unassigned, meaning do not restrict the type.

NAME	slpd.reg – serialized registration file for the service location protocol daemon (slpd)
SYNOPSIS	/etc/inet/slpd.reg
DESCRIPTION	<p>The serialized registration file contains a group of registrations that <code>slpd(1M)</code> registers when it starts. These registrations are primarily for older service programs that do not internally support SLP and cannot be converted. The character format of the registration file is required to be ASCII. To use serialized registrations, set the <code>net.slp.serializedRegURL</code> property in <code>slp.conf(4)</code> to point at a valid <code>slpd.reg</code> file. The syntax of the serialized registration file, in ABNF format (see <i>RFC 2234</i>), is as follows:</p> <pre> ser-file = reg-list reg-list = reg / reg reg-list reg = creg / ser-reg creg = comment-line ser-reg comment-line = ("#" / ";") 1*allchar newline ser-reg = url-props [slist] [attr-list] newline url-props = surl "," lang "," ltime ["," type] newline surl = ;The registration's URL. See ; [8] for syntax. lang = 1*8ALPHA ["-" 1*8ALPHA] ;RFC 1766 Language Tag see [6]. ltime = 1*5DIGIT ; A positive 16-bit integer ; giving the lifetime ; of the registration. type = ; The service type name, see [7] ; and [8] for syntax. slist = "scopes" "=" scope-list newline scope-list = scope-name / scope-name "," scope-list scope = ; See grammar of [7] for ; scope-name syntax. attr-list = attr-def / attr-def attr-list attr-def = (attr / keyword) newline keyword = attr-id attr = attr-id "=" attr-val-list attr-id = ;Attribute id, see [7] for syntax. attr-val-list = attr-val / attr-val "," attr-val-list attr-val = ;Attribute value, see [7] for syntax allchar = char / WSP char = DIGIT / ALPHA / other other = %x21-%x2f / %x3a-%x40 / %x5b-%x60 / %7b-%7e ; All printable, nonwhitespace US-ASCII ; characters. newline = CR / (CRLF) </pre> <p>The syntax for attributes and attribute values requires that you use a backslash to escape special characters, in addition to non-ASCII characters, as specified in <i>RFC 2608</i>. The <code>slpd</code> command handles serialized registrations exactly as if they were registered by an SA. In the <code>url-props</code> production, the <code>type</code> token is optional. If the <code>type</code> token is present for a service: URL, a warning is signalled, and the <code>type</code> name is</p>

slpd.reg(4)

ignored. If the maximum lifetime of 65535 seconds is specified, the registration is taken to be permanent, and it is continually refreshed by the DA or SA server until it exits.

Scopes can be included in a registration by including an attribute definition with tag `scopes` followed by a comma-separated list of scope names immediately after the `url-props` production. If the optional `scope-list` is present, the registrations are made in the indicated scopes; otherwise, they are registered in the scopes with which the DA or SA server was configured through the `net.slp.useScopes` property. If any conflicts occur between the scope list and the `net.slp.useScopes` property, an error message is issued by way of `syslog(3C)`. Refer to information regarding `LOG_INFO` in `syslog(3C)`.

Service advertisements are separated by a single blank line. Additionally, the file must end with a single blank line.

EXAMPLES **EXAMPLE 1** Using a Serialized Registration File

The following serialized registration file shows an instance of the service type `foo`, with a lifetime of 65535 seconds, in the `en` locale, with scope `somescope`:

```
# register foo
service:foo://fooserver/foopath,en,65535
scopes=somescope
description=bogus
security=kerberos_v5
location=headquarters

# next registration...
```

space(4)

NAME	space – disk space requirement file
DESCRIPTION	<p>space is an ASCII file that gives information about disk space requirements for the target environment. The space file defines space needed beyond what is used by objects defined in the prototype(4) file; for example, files which will be installed with the installf(1M) command. The space file should define the maximum amount of additional space that a package will require.</p> <p>The generic format of a line in this file is:</p> <p><i>pathname blocks inodes</i></p> <p>Definitions for the fields are as follows:</p> <p><i>pathname</i> Specify a directory name which may or may not be the mount point for a filesystem. Names that do not begin with a slash ('/') indicate relocatable directories.</p> <p><i>blocks</i> Define the number of disk blocks required for installation of the files and directory entries contained in the pathname (using a 512-byte block size).</p> <p><i>inodes</i> Define the number of inodes required for installation of the files and directory entries contained in the pathname.</p>
EXAMPLES	<p>EXAMPLE 1 A sample file.</p> <pre># extra space required by config data which is # dynamically loaded onto the system data 500 1</pre>
SEE ALSO	<p>installf(1M), prototype(4)</p> <p><i>Application Packaging Developer's Guide</i></p>

NAME	ssh_config – ssh configuration file
SYNOPSIS	<pre>/etc/ssh/ssh_config \$HOME/.ssh/config</pre>
DESCRIPTION	<p>The first version of <code>ssh_config</code>, above, is the host view of defaults for <code>ssh(1)</code>. The second version is user-specific defaults for <code>ssh</code>.</p> <p><code>ssh</code> obtains configuration data from the following sources (in this order): command line options, user's configuration file (<code>\$HOME/.ssh/config</code>), and system-wide configuration file (<code>/etc/ssh/ssh_config</code>). For each parameter, the first obtained value will be used. The configuration files contain sections bracketed by <code>Host</code> specifications, and that section is applied only for hosts that match one of the patterns given in the specification. The matched host name is the one given on the command line.</p> <p>Since the first obtained value for each parameter is used, host-specific declarations should be given near the beginning of the file, and general defaults at the end.</p> <p>In the configuration file, empty lines and lines starting with a hash mark (#) are comments. Otherwise, a line is of the format: <i>keyword arguments</i>. Interpretation of the file is case-sensitive. The possible keywords and their meanings are as follows:</p> <p>Host Restricts the following declarations (up to the next <code>Host</code> keyword) to be only for those hosts that match one of the patterns given after the keyword. Asterisk (*) and question mark (?) can be used as wildcards in the patterns. A single * as a pattern can be used to provide global defaults for all hosts. The host is the hostname argument given on the command line (that is, the name is not converted to a canonicalized host name before matching).</p> <p>BatchMode The argument must be <code>yes</code> or <code>no</code>. If set to <code>yes</code>, passphrase/password querying will be disabled. This option is useful in scripts and other batch jobs where you have no user to supply the password.</p> <p>CheckHostIP If this flag is set to <code>yes</code>, <code>ssh</code> will additionally check the host IP address in the <code>known_hosts</code> file. This allows <code>ssh</code> to detect if a host key changed due to DNS spoofing. If the option is set to <code>no</code>, the check will not be executed.</p> <p>Cipher Specifies the cipher to use for encrypting the session in protocol version 1; <code>blowfish</code> and <code>3des</code> are the only valid values. Specifies the ciphers allowed for protocol version 2 in order of preference. Multiple ciphers must be comma-separated. The default is <code>3des-cbc,blowfish-cbc,aes-128-cbc</code>.</p> <p>Compression Specifies whether to use compression. The argument must be <code>yes</code> or <code>no</code>.</p>

ssh_config(4)

CompressionLevel

Specifies the compression level to use if compression is enabled. The argument must be an integer from 1 (fast) to 9 (slow, best). The default level is 6, which is good for most applications..

ConnectionAttempts

Specifies the number of tries (one per second) to make before falling back to `rsh` or exiting. The argument must be an integer. This can be useful in scripts if the connection sometimes fails.

DSAAuthentication

Specifies whether to try DSA authentication. The argument to this keyword must be `yes` or `no`. DSA authentication is attempted only if a DSA identity file exists. Note that this option applies to protocol version 2 only.

EscapeChar

Sets the escape character. The default is tilde (`~`). The escape character can also be set on the command line. The argument should be a single character, `^`, followed by a letter, or `none` to disable the escape character entirely (making the connection transparent for binary data).

FallBackToRsh

Specifies that if connecting with `ssh` fails due to a connection refused error (there is no `sshd(8)` listening on the remote host), `rsh(1)` should automatically be used instead (after a suitable warning about the session being unencrypted). The argument must be `yes` or `no`.

ForwardAgent

Specifies whether the connection to the authentication agent (if any) will be forwarded to the remote machine. The argument must be `yes` or `no`. The default is `no`.

ForwardX11

Specifies whether X11 connections will be automatically redirected over the secure channel and `DISPLAY` set. The argument must be `yes` or `no`. The default is `no`.

GatewayPorts

Specifies whether remote hosts are allowed to connect to local forwarded ports. The argument must be `yes` or `no`. The default is `no`.

GlobalKnownHostsFile

Specifies a file to use instead of `/etc/ssh_known_hosts`.

HostName

Specifies the real host name to log into. This can be used to specify nicknames or abbreviations for hosts. Default is the name given on the command line. Numeric IP addresses are also permitted (both on the command line and in `HostName` specifications).

IdentityFile

Specifies the file from which the user's RSA authentication identity is read. The default is `$HOME/.ssh/identity` in the user's home directory. Additionally, any

identities represented by the authentication agent will be used for authentication. The file name can use the tilde (~) syntax to refer to a user's home directory. It is possible to have multiple identity files specified in configuration files; all of these identities will be tried in sequence.

IdentityFile2

Specifies the file from which the user's DSA authentication identity is read. The default is `$HOME/.ssh/id_dsa` in the user's home directory. The file name can use the tilde (~) syntax to refer to a user's home directory. It is possible to have multiple identity files specified in configuration files; all of these identities will be tried in sequence.

KeepAlive

Specifies whether the system should send keepalive messages to the other side. If they are sent, death of the connection or crash of one of the machines will be properly noticed. However, this means that connections die if the route is down temporarily, which can be a source of annoyance.

The default is `yes` (to send keepalives), which means the client notices if the network goes down or the remote host dies. This is important in scripts, and many users want it too. To disable keepalives, the value should be set to `no` in both the server and the client configuration files.

LocalForward

Specifies that a TCP/IP port on the local machine be forwarded over the secure channel to a given `host:port` from the remote machine. The first argument must be a port number, and the second must be `host:port`. Multiple forwardings may be specified, and additional forwardings can be given on the command line. Only the superuser can forward privileged ports.

LogLevel

Gives the verbosity level that is used when logging messages from `ssh`. The possible values are: `QUIET`, `FATAL`, `ERROR`, `INFO`, `VERBOSE` and `DEBUG`. The default is `INFO`.

NumberOfPasswordPrompts

Specifies the number of password prompts before giving up. The argument to this keyword must be an integer. The default is 3.

PasswordAuthentication

Specifies whether to use password authentication. The argument to this keyword must be `yes` or `no`. Note that this option applies to both protocol versions 1 and 2.

Port

Specifies the port number to connect on the remote host. The default is 22.

Protocol

Specifies the protocol versions `ssh` should support in order of preference. The possible values are 1 and 2. Multiple versions must be comma-separated. The default is 1, 2. This means that `ssh` tries version 1 and falls back to version 2 if version 1 is not available.

ssh_config(4)

ProxyCommand

Specifies the command to use to connect to the server. The command string extends to the end of the line, and is executed with `/bin/sh`. In the command string, `%h` is substituted by the host name to connect and `%p` by the port. The string can be any valid command, and should read from its standard input and write to its standard output. It should eventually connect an `sshd(1M)` server running on some machine, or execute `sshd -i` somewhere. Host key management will be done using the `HostName` of the host being connected (defaulting to the name typed by the user). Note that `CheckHostIP` is not available for connects with a proxy command.

RemoteForward

Specifies that a TCP/IP port on the remote machine be forwarded over the secure channel to a given `host:port` from the local machine. The first argument must be a port number, and the second must be `host:port`. You can specify multiple forwardings and give additional forwardings on the command line. Only the superuser can forward privileged ports.

RhostsAuthentication

Specifies whether to try `rhosts`-based authentication. Note that this declaration affects only the client side and has no effect whatsoever on security. Disabling `rhosts` authentication can reduce authentication time on slow connections when `rhosts` authentication is not used. Most servers do not permit `RhostsAuthentication` because it is not secure (see `RhostsRSAAuthentication`). The argument to this keyword must be `yes` or `no`.

RhostsRSAAuthentication

Specifies whether to try `rhosts`-based authentication with RSA host authentication. This is the primary authentication method for most sites. The argument must be `yes` or `no`.

StrictHostKeyChecking

If this flag is set to `yes`, `ssh` will never automatically add host keys to the `$HOME/.ssh/known_hosts` file, and will refuse to connect hosts whose host key has changed. This provides maximum protection against trojan horse attacks. However, it can be a source of inconvenience if you do not have good `/etc/ssh_known_hosts` files installed and frequently connect new hosts. This option forces the user to manually add any new hosts. Normally this option is disabled, and new hosts will automatically be added to the known host files. The host keys of known hosts will be verified automatically in either case. The argument must be `yes` or `no`.

UsePrivilegedPort

Specifies whether to use a privileged port for outgoing connections. The argument must be `yes` or `no`. The default is `yes`. Note that setting this option to `no` turns off `RhostsAuthentication` and `RhostsRSAAuthentication`.

User

Specifies the user to log in as. This can be useful if you have different user names on different machines. This saves you the trouble of having to remember to enter the user name on the command line.

UserKnownHostsFile

Specifies a file to use instead of `$HOME/.ssh/known_hosts`.

UserRsh

Specifies that `rlogin` or `rsh` should be used for this host. It is possible that the host does not support the `ssh` protocol. This causes `ssh` to immediately execute `rsh(1)`. All other options (except `HostName`) are ignored if this has been specified. The argument must be `yes` or `no`.

XAuthLocation

Specifies the location of the `xauth(1)` program. The default is `/usr/X11R6/bin/xauth`.

SEE ALSO `ssh(1)`, `sshd_config(4)`

sshd_config(4)

NAME	sshd_config – sshd configuration file
SYNOPSIS	/etc/ssh/sshd_config
DESCRIPTION	<p>The sshd(1M) daemon reads configuration data from /etc/ssh/sshd_config (or the file specified with sshd -f on the command line). The file contains keyword-value pairs, one per line. A line starting with a hash mark (#) and empty lines are interpreted as comments.</p> <p>The sshd_config file supports the following keywords:</p> <p>AllowGroups This keyword can be followed by a number of group names, separated by spaces. If specified, login is allowed only for users whose primary group matches one of the patterns. Asterisk (*) and question mark (?) can be used as wildcards in the patterns. Only group names are valid; a numerical group ID is not recognized. By default, login is allowed regardless of the primary group.</p> <p>AllowTcpForwarding Specifies whether TCP forwarding is permitted. The default is yes. Note that disabling TCP forwarding does not improve security unless users are also denied shell access, as they can always install their own forwarders.</p> <p>AllowUsers This keyword can be followed by a number of user names, separated by spaces. If specified, login is allowed only for user names that match one of the patterns. Asterisk (*) and question mark (?) can be used as wildcards in the patterns. Only user names are valid; a numerical user ID is not recognized. By default login is allowed regardless of the user name.</p> <p>Ciphers Specifies the ciphers allowed for protocol version 2. Multiple ciphers must be comma-separated. The default is 3des-cbc,blowfish-cbc,aes-128-cbc.</p> <p>CheckMail Specifies whether sshd should check for new mail for interactive logins. The default is no.</p> <p>DenyGroups Can be followed by a number of group names, separated by spaces. Users whose primary group matches one of the patterns are not allowed to log in. Asterisk (*) and question mark (?) can be used as wildcards in the patterns. Only group names are valid; a numerical group ID is not recognized. By default, login is allowed regardless of the primary group.</p> <p>DenyUsers Can be followed by a number of user names, separated by spaces. Login is disallowed for user names that match one of the patterns. Asterisk (*) and question mark (?) can be used as wildcards in the patterns. Only user names are valid; a numerical user ID is not recognized. By default, login is allowed regardless of the user name.</p>

DSAAuthentication

Specifies whether DSA authentication is allowed. The default is `yes`. Note that this option applies only to protocol version 2.

GatewayPorts

Specifies whether remote hosts are allowed to connect to ports forwarded for the client. The argument must be `yes` or `no`. The default is `no`.

HostKey

Specifies the file containing the private RSA host key (default `/etc/ssh_host_key`) used by SSH protocols 1.3 and 1.5. Note that `sshd` disables protocols 1.3 and 1.5 if this file is group/world-accessible.

IgnoreRhosts

Specifies that `.rhosts` and `.shosts` files will not be used in authentication. `/etc/hosts.equiv` and `/etc/shosts.equiv` are still used. The default is `yes`.

IgnoreUserKnownHosts

Specifies whether `sshd` should ignore the user's `$HOME/.ssh/known_hosts` during `RhostsRSAAuthentication`. The default is `no`.

KeepAlive

Specifies whether the system should send keepalive messages to the other side. If they are sent, death of the connection or crash of one of the machines will be properly noticed. However, this means that connections will die if the route is down temporarily, which can be an annoyance. On the other hand, if keepalives are not sent, sessions can hang indefinitely on the server, leaving "ghost" users and consuming server resources.

The default is `yes` (to send keepalives), and the server will notice if the network goes down or the client host reboots. This avoids infinitely hanging sessions.

To disable keepalives, the value should be set to `no` in both the server and the client configuration files.

KeyRegenerationInterval

The server key is automatically regenerated after this many seconds (if it has been used). The purpose of regeneration is to prevent decrypting captured sessions by later breaking into the machine and stealing the keys. The key is never stored anywhere. If the value is 0, the key is never regenerated. The default is 3600 (seconds).

ListenAddress

Specifies what local address `sshd` should listen on. The default is to listen to all local addresses. Multiple options of this type are permitted. Additionally, the `Ports` options must precede this option.

LoginGraceTime

The server disconnects after this time if the user has not successfully logged in. If the value is 0, there is no time limit. The default is 600 (seconds).

sshd_config(4)

LogLevel

Gives the verbosity level that is used when logging messages from `sshd`. The possible values are: `QUIET`, `FATAL`, `ERROR`, `INFO`, `VERBOSE`, and `DEBUG`. The default is `INFO`. Logging with level `DEBUG` violates the privacy of users and is not recommended.

MaxStartups

Specifies the maximum number of concurrent unauthenticated connections to the `sshd` daemon. Additional connections will be dropped until authentication succeeds or the `LoginGraceTime` expires for a connection. The default is 10.

Alternatively, random early drop can be enabled by specifying the three colon-separated values `start:rate:full` (for example, `10:30:60`). Referring to this example, `sshd` will refuse connection attempts with a probability of $rate/100$ (30% in our example) if there are currently 10 (from the `start` field) unauthenticated connections. The probability increases linearly and all connection attempts are refused if the number of unauthenticated connections reaches `full` (60 in our example).

PasswordAuthentication

Specifies whether password authentication is allowed. The default is `yes`. Note that this option applies to both protocol versions 1 and 2.

PermitEmptyPasswords

When password authentication is allowed, it specifies whether the server allows login to accounts with empty password strings. The default is `no`.

PermitRootLogin

Specifies whether the root can log in using `ssh()`. The argument must be `yes`, `without-password`, or `no`. The default is `yes`. If this option is set to `without-password` only password authentication is disabled for root.

Root login with RSA authentication when the command option has been specified will be allowed regardless of the value of this setting. This might be useful for taking remote backups even if root login is normally not allowed.

Port

Specifies the port number that `sshd` listens on. The default is 22. Multiple options of this type are permitted.

PrintMotd

Specifies whether `sshd` should display the contents of `/etc/motd` when a user logs in interactively. (On some systems it is also displayed by the shell or a shell startup file, such as `/etc/profile`.) The default is `yes`.

Protocol

Specifies the protocol versions `sshd` should support. The possible values are 1 and 2. Multiple versions must be comma-separated. The default is 1.

RhostsAuthentication

Specifies whether authentication using `rhosts` or `/etc/hosts.equiv` files is sufficient. Normally, this method should not be permitted because it is insecure. `RhostsRSAAuthentication` should be used instead, because it performs RSA-based host authentication in addition to normal `rhosts` or `/etc/hosts.equiv` authentication. The default is `no`.

RhostsRSAAuthentication

Specifies whether `rhosts` or `/etc/hosts.equiv` authentication together with successful RSA host authentication is allowed. The default is `no`.

RSAAuthentication

Specifies whether pure RSA authentication is allowed. The default is `yes`. Note that this option applies to protocol version 1 only.

ServerKeyBits

Defines the number of bits in the server key. The minimum value is 512, and the default is 768.

StrictModes

Specifies whether `sshd` should check file modes and ownership of the user's files and home directory before accepting login. This is normally desirable because novices sometimes accidentally leave their directory or files world-writable. The default is `yes`.

Subsystem

Configures an external subsystem (for example, a file transfer daemon). Arguments should be a subsystem name and a command to execute upon subsystem request. The command `sftp-server(1M)` implements the `sftp` file transfer subsystem. By default, no subsystems are defined. Note that this option applies to protocol version 2 only.

SyslogFacility

Gives the facility code that is used when logging messages from `sshd`. The possible values are: `DAEMON`, `USER`, `AUTH`, `LOCAL0`, `LOCAL1`, `LOCAL2`, `LOCAL3`, `LOCAL4`, `LOCAL5`, `LOCAL6`, and `LOCAL7`. The default is `AUTH`.

X11DisplayOffset

Specifies the first display number available for `sshd`'s X11 forwarding. This prevents `sshd` from interfering with real X11 servers. The default is 10.

X11Forwarding

Specifies whether X11 forwarding is permitted. The default is `no`. Note that disabling X11 forwarding does not improve security in any way, as users can always install their own forwarders.

XAuthLocation

Specifies the location of the `xauth(1)` program. The default is `/usr/X/bin/xauth`.

SEE ALSO `sshd(1M)`, `ssh_config(4)`

su(4)

NAME	su(4) – su command log file
SYNOPSIS	/var/adm/sulog
DESCRIPTION	<p>The <code>su(4)</code> file is a record of all attempts by users on the system to execute the <code>su(1M)</code> command. Each time <code>su(1M)</code> is executed, an entry is added to the <code>su(4)</code> file.</p> <p>Each entry in the <code>su(4)</code> file is a single line of the form:</p> <pre>SU date time result port user-newuser</pre> <p>where</p> <p>date The month and date <code>su(1M)</code> was executed. <code>date</code> is displayed in the form <code>mm/dd</code> where <code>mm</code> is the month number and <code>dd</code> is the day number in the month.</p> <p>time The time <code>su(1M)</code> was executed. <code>time</code> is displayed in the form <code>HH/MM</code> where <code>HH</code> is the hour number (24 hour system) and <code>MM</code> is the minute number.</p> <p>result The result of the <code>su(1M)</code> command. A <code>' + '</code> sign is displayed in this field if the <code>su</code> attempt was successful; otherwise a <code>' - '</code> sign is displayed.</p> <p>port The name of the terminal device from which <code>su(1M)</code> was executed.</p> <p>user The user id of the user executing the <code>su(1M)</code> command.</p> <p>newuser The user id being switched to with <code>su(1M)</code>.</p>
EXAMPLES	<p>EXAMPLE 1 A sample <code>su(4)</code> file.</p> <p>Here is a sample <code>su(4)</code> file:</p> <pre>SU 02/25 09:29 + console root-sys SU 02/25 09:32 + pts/3 user1-root SU 03/02 08:03 + pts/5 user1-root SU 03/03 08:19 + pts/5 user1-root SU 03/09 14:24 - pts/5 guest3-root SU 03/09 14:24 - pts/5 guest3-root SU 03/14 08:31 + pts/4 user1-root</pre>

SEE ALSO	<code>su(1M)</code>

NAME	sysbus, isa, eisa – device tree properties for ISA and EISA bus device drivers
DESCRIPTION	<p>Solaris (Intel Platform Edition) supports the ISA and EISA buses as the system bus. Drivers for devices on these buses use the device tree built by the booting system to retrieve the necessary system resources used by the driver. These resources include device I/O port addresses, any interrupt capabilities that the device may have, any DMA channels it may require, and any memory-mapped addresses it may occupy.</p> <p>Configuration files for ISA and EISA device drivers are only necessary to describe properties used by a particular driver that are not part of the standard properties found in the device tree. See <code>driver.conf(4)</code> for further details of configuration file syntax.</p> <p>The ISA and EISA nexus drivers all belong to class <code>sysbus</code>. All bus drivers of class <code>sysbus</code> recognize the following properties:</p> <p>interrupts An arbitrary-length array where each element of the array represents a hardware interrupt (IRQ) that is used by the device. In general, this array only has one entry unless a particular device uses more than one IRQ.</p> <p>Solaris defaults all ISA and EISA interrupts to IPL 5. This interrupt priority may be overridden by placing an <code>interrupt-priorities</code> property in a <code>.conf</code> file for the driver. Each entry in the array of integers for the <code>interrupt-priorities</code> property is matched one-to-one with the elements in the <code>interrupts</code> property to specify the IPL value that will be used by the system for this interrupt in this driver. This is the priority that this device's interrupt handler will receive relative to the interrupt handlers of other drivers. The priority is an integer from 1 to 16. Generally, disks are assigned a priority of 5, while mice and printers are lower, and serial communication devices are higher, typically 7. 10 is reserved by the system and must not be used. Priorities 11 and greater are high level priorities and are generally not recommended (see <code>ddi_intr_hilevel(9F)</code>).</p> <p>The driver can refer to the elements of this array by index using <code>ddi_add_intr(9F)</code>. The index into the array is passed as the <i>inumber</i> argument of <code>ddi_add_intr()</code>.</p> <p>Only devices that generate interrupts will have an <code>interrupts</code> property.</p> <p>reg An arbitrary-length array where each element of the array consists of a 3-tuple of integers. Each array element describes a contiguous memory address range associated with the device on the bus.</p>

sysbus(4)

The first integer of the tuple specifies the memory type, 0 specifies a memory range and 1 specifies an I/O range. The second integer specifies the base address of the memory range. The third integer of each 3-tuple specifies the size, in bytes, of the mappable region.

The driver can refer to the elements of this array by index, and construct kernel mappings to these addresses using `ddi_map_regs(9F)`. The index into the array is passed as the *number* argument of `ddi_map_regs()`.

All sysbus devices will have `reg` properties. The first tuple of this property is used to construct the address part of the device name under `/devices`. In the case of Plug and Play ISA devices, the first tuple is a special tuple that does not denote a memory range, but is used by the system only to create the address part of the device name. This special tuple can be recognized by determining if the top bit of the first integer is set to a one.

The order of the tuples in the `reg` property is determined by the boot system probe code and depends on the characteristics of each particular device. However, the `reg` property will maintain the same order of entries from system boot to system boot. The recommended way to determine the `reg` property for a particular device is to use the `prtconf(1M)` command after installing the particular device. The output of the `prtconf` command can be examined to determine the `reg` property for any installed device.

You can use the `ddi_get*` and `ddi_put*` family of functions to access register space from a high-level interrupt context.

`dma-channels` A list of integers that specifies the DMA channels used by this device. Only devices that use DMA channels will have a `dma-channels` property.

It is recommended that drivers for devices connected to the system bus recognize the following standard property names:

`slot` The number of the slot containing the device, if known. (Only for EISA devices).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	IA

Writing Device Drivers

sysidcfg(4)

NAME	sysidcfg – system identification configuration file
DESCRIPTION	<p>When a diskless client boots for the first time or a system installs over the network, the booting software tries to obtain configuration information about the system (such as the system's root password or name service) from, first, a <code>sysidcfg</code> file and then the name service databases. If the booting software cannot find the information, it prompts the user for it. Like the name service databases, the <code>sysidcfg</code> file can be used to avoid the user prompts and provide a totally hands-off booting process.</p> <p>The <code>sysidcfg</code> file preconfigures information through a set of keywords. You can specify one or more of the keywords to preconfigure as much information as you want. Each set of systems (one or more) that has unique configuration information must have its own <code>sysidcfg</code> file. For example, you can use the same <code>sysidcfg</code> file to preconfigure the time zone for multiple systems if you want all the systems to have the same time zone configured. However, if you want to preconfigure a different root password for each of those systems, then each system would need its own <code>sysidcfg</code> file.</p>
Where To Put the sysidcfg File	<p>The <code>sysidcfg</code> file can reside on a shared NFS network directory or the root directory on a UFS or PCFS diskette in the system's diskette drive. If you put the <code>sysidcfg</code> file on a shared NFS network directory, you have to use the <code>-p</code> option of the <code>add_install_client(1M)</code> command (see <code>install_scripts(1M)</code>) to specify where the system being installed can find the <code>sysidcfg</code> file. If you put the <code>sysidcfg</code> file on a diskette, you need to make sure the diskette is in the system's diskette drive when the system boots (on IA systems, the <code>sysidcfg</code> file should reside on the Solaris Device Configuration Assistant diskette).</p> <p>Only one <code>sysidcfg</code> file can reside in a directory or diskette. If you are creating more than one <code>sysidcfg</code> file, they must reside in different directories or diskettes.</p>
Keyword Syntax Rules	<p>The following rules apply to the keywords in a <code>sysidcfg</code> file:</p> <ul style="list-style-type: none">■ Keywords can be in any order■ Keywords are not case-sensitive■ Keyword values can be optionally enclosed in single (') or double (") quotes■ Only the first instance of a keyword is valid; if you specify the same keyword more than once, the first keyword specified will be used.
Keywords – All Platforms	<p>The following keywords apply to both SPARC and IA platforms.</p> <p>Name Service, Domain Name, Name Server</p> <p>Naming-related keywords are as follows:</p> <pre>name_service=NIS,NIS+,LDAP,DNS,NONE</pre> <p>For the NIS and NIS+ keywords, the options are:</p> <pre>domain_name=domain_name name_server=hostname(ip_address)</pre>

The following is an example NIS entry:

```
name_service=NIS
{domain_name=west.arp.com name_server=timber(129.221.2.1)}
```

For NIS+, the example is identical to the one above, except for the replacement of the keyword NIS by NIS+.

For DNS, the syntax is:

```
domain_name=domain_name; name_server=ip_address, ... ;
search=domain_name, ...
```

You can have a maximum of three IP addresses and six domain names. The total length of a search entry cannot exceed 250 characters. The following is an example DNS entry:

```
name_service=DNS
{domain_name=west.arp.com
name_server=10.0.1.10,10.0.1.20
search=arp.com,east.arp.com}
```

For LDAP, the syntax is:

```
domain_name=domain_name;
profile=profile_name;
profile_server=ip_address
```

The following is an example LDAP entry:

```
name_service=LDAP
{domain_name=west.arp.com
profile=default
profile_server=129.221.2.1}
```

Choose only one value for `name_service`. Include either, both, or neither of the `domain_name` and `name_server` keywords, as needed. If no keywords are used, omit the curly braces.

Network Interface, Hostname, IP address, Netmask, DHCP, IPv6, Default Route

Network-related keywords are as follows:

```
network_interface=NONE, PRIMARY, value
```

If you are using DHCP, the options for PRIMARY and *value* are:

```
dhcp; protocol_ipv6=yes_or_no
```

For example:

```
network_interface=primary {dhcp protocol_ipv6=yes}
```

If you are not using DHCP, the options for PRIMARY and *value* are:

```
hostname=host_name;
ip_address=ip_address;
```

sysidcfg(4)

```
netmask=netmask;  
protocol_ipv6=yes_or_no  
default_route=ip_address (IPv4 address only)
```

For example:

```
network_interface=le0  
{hostname=feron  
ip_address=129.222.2.7  
netmask=255.255.0.0  
protocol_ipv6=no  
default_route=129.222.2.1}
```

Choose only one value for `network_interface`. Include any combination or none of the `hostname`, `ip_address`, `netmask`, and `default_route` keywords, as needed. If you do not use any of these keywords, omit the curly braces.

`protocol_ipv6` and `default_route` are optional; you do not need to specify them. `default_route` accepts only an IPv4 address.

Root Password

The root password keyword is `root_password`. Possible values are encrypted from `/etc/shadow`. Syntax is:

```
root_password=encrypted_password
```

Security Policy

The security—related keyword is `security_policy`. It has the following syntax:

```
security_policy=kerberos, NONE
```

The `kerberos` keyword has the following options:

```
{default_realm=FQDN admin_server=FQDN kdc=FQDN1, FQDN2, FQDN3}
```

where *FQDN* is a fully qualified domain name. An example of the `security_policy` keyword is as follows:

```
security_policy=kerberos {default_realm=Yoursite.COM  
admin_server=krbadmin.Yoursite.COM  
kdc=kdc1.Yoursite.COM, kdc2.Yoursite.COM}
```

You can list a maximum of three key distribution centers (KDCs) for a `security_policy` keyword. At least one is required.

Language in Which to Display the Install Program

The system-location keyword is `system_locale`. It has the following syntax:

```
system_locale=locale
```

where *locale* is `/usr/lib/locale`.

Terminal Type

The terminal keyword is `terminal`. It has the following syntax:

```
terminal=terminal_type
```

where *terminal_type* is a value from `/usr/share/lib/terminfo/*`.

Timezone Information

The timezone keyword is `timezone`. It has the following syntax:

```
timezone=timezone
```

where *timezone* is a value from `/usr/share/lib/zoneinfo/*`.

Date and Time

The time server keyword is `timeserver`. It has the following syntax:

```
timeserver=localhost
timeserver=hostname
timeserver=ip_address
```

If you specify `localhost` as the time server, the system's time is assumed to be correct. If you specify the `hostname` or *ip_address* (if you are not running a name service) of a system, that system's time is used to set the time.

Keywords — IA Platform

The following keywords apply only to IA platforms. For all these keywords, use `kdmconfig -d` to create or append to the `sysidcfg` file. See `kdmconfig(1M)`

Monitor type

The monitor—related keyword is `monitor`. The syntax is:

```
monitor=monitor_type
```

Keyboard language, keyboard layout

The keyboard—language keyword is `keyboard`. The syntax is:

```
keyboard=keyboard_language {layout=value}
```

Graphics card, color depth, display resolution, screen size

The display-related keywords are `display`, `size`, `depth`, and `resolution`. The syntax is:

```
display=graphics_card {size=screen_size
depth=color_depth resolution=screen_resolution}
```

Pointing device, number of buttons, IRQ level

The mouse-related keywords are `pointer`, `nbuttons`, and `irq`.

```
pointer=pointing_device {nbuttons=number_buttons
irq=value}
```

EXAMPLES

EXAMPLE 1 Sample `sysidcfg` files

The following example is a `sysidcfg` file for a group of SPARC systems to install over the network. (The host names, IP addresses, and netmask of these systems have been preconfigured by editing the name service.) Because all the system configuration

sysidcfg(4)

EXAMPLE 1 Sample sysidcfg files (Continued)

information has been preconfigured, an automated installation can be created by using a custom JumpStart profile.

```
system_locale=en_US
timezone=US/Central
timeserver=localhost
terminal=sun-cmd
name_service=NIS {domain_name=marquee.central.sun.com
                  name_server=connor(129.152.112.3)}
root_password=m4QPOWNY
system_locale=C
security_policy=kerberos
                 {default_realm=Yoursite.COM
                  admin_server=krbadmin.Yoursite.COM
                  kdc=kdc1.Yoursite.COM, kdc2.Yoursite.COM}
```

The following example is a `sysidcfg` file created for a group of IA systems to install over the network that all have the same keyboard, graphics cards, and pointing devices. The device information (keyboard, display, and pointer) was captured from running `kdmconfig -d` (see `kdmconfig(1M)`). In this example, users would see only the prompt to select a language (*system_locale*) for displaying the rest of the Solaris installation program.

```
keyboard=ATKBD {layout=US-English}
display=ati {size=15-inch}
pointer=MS-S
timezone=US/Central
timeserver=connor
terminal=AT386
name_service=NIS {domain_name=marquee.central.sun.com
                  name_server=connor(129.152.112.3)}
root_password=URFUni9
security_policy=none
```

Solaris 9 Installation Guide

NAME	syslog.conf – configuration file for syslogd system log daemon																										
SYNOPSIS	/etc/syslog.conf																										
DESCRIPTION	<p>The file <code>/etc/syslog.conf</code> contains information used by the system log daemon, <code>syslogd(1M)</code>, to forward a system message to appropriate log files and/or users. <code>syslogd</code> preprocesses this file through <code>m4(1)</code> to obtain the correct information for certain log files, defining <code>LOGHOST</code> if the address of "loghost" is the same as one of the addresses of the host that is running <code>syslogd</code>.</p> <p>A configuration entry is composed of two TAB-separated fields:</p> <pre>selector action</pre> <p>The <i>selector</i> field contains a semicolon-separated list of priority specifications of the form:</p> <pre>facility.level [; facility.level]</pre> <p>where <i>facility</i> is a system facility, or comma-separated list of facilities, and <i>level</i> is an indication of the severity of the condition being logged. Recognized values for <i>facility</i> include:</p> <table> <tr> <td>user</td> <td>Messages generated by user processes. This is the default priority for messages from programs or facilities not listed in this file.</td> </tr> <tr> <td>kern</td> <td>Messages generated by the kernel.</td> </tr> <tr> <td>mail</td> <td>The mail system.</td> </tr> <tr> <td>daemon</td> <td>System daemons, such as <code>in.ftpd(1M)</code></td> </tr> <tr> <td>auth</td> <td>The authorization system: <code>login(1)</code>, <code>su(1M)</code>, <code>getty(1M)</code>, among others.</td> </tr> <tr> <td>lpr</td> <td>The line printer spooling system: <code>lpr(1B)</code>, <code>lpc(1B)</code>, among others.</td> </tr> <tr> <td>news</td> <td>Reserved for the USENET network news system.</td> </tr> <tr> <td>uucp</td> <td>Reserved for the UUCP system; it does not currently use the <code>syslog</code> mechanism.</td> </tr> <tr> <td>cron</td> <td>The cron/at facility; <code>crontab(1)</code>, <code>at(1)</code>, <code>cron(1M)</code>, among others.</td> </tr> <tr> <td>local0-7</td> <td>Reserved for local use.</td> </tr> <tr> <td>mark</td> <td>For timestamp messages produced internally by <code>syslogd</code>.</td> </tr> <tr> <td>*</td> <td>An asterisk indicates all facilities except for the mark facility.</td> </tr> </table> <p>Recognized values for <i>level</i> are (in descending order of severity):</p> <table> <tr> <td>emerg</td> <td>For panic conditions that would normally be broadcast to all users.</td> </tr> </table>	user	Messages generated by user processes. This is the default priority for messages from programs or facilities not listed in this file.	kern	Messages generated by the kernel.	mail	The mail system.	daemon	System daemons, such as <code>in.ftpd(1M)</code>	auth	The authorization system: <code>login(1)</code> , <code>su(1M)</code> , <code>getty(1M)</code> , among others.	lpr	The line printer spooling system: <code>lpr(1B)</code> , <code>lpc(1B)</code> , among others.	news	Reserved for the USENET network news system.	uucp	Reserved for the UUCP system; it does not currently use the <code>syslog</code> mechanism.	cron	The cron/at facility; <code>crontab(1)</code> , <code>at(1)</code> , <code>cron(1M)</code> , among others.	local0-7	Reserved for local use.	mark	For timestamp messages produced internally by <code>syslogd</code> .	*	An asterisk indicates all facilities except for the mark facility.	emerg	For panic conditions that would normally be broadcast to all users.
user	Messages generated by user processes. This is the default priority for messages from programs or facilities not listed in this file.																										
kern	Messages generated by the kernel.																										
mail	The mail system.																										
daemon	System daemons, such as <code>in.ftpd(1M)</code>																										
auth	The authorization system: <code>login(1)</code> , <code>su(1M)</code> , <code>getty(1M)</code> , among others.																										
lpr	The line printer spooling system: <code>lpr(1B)</code> , <code>lpc(1B)</code> , among others.																										
news	Reserved for the USENET network news system.																										
uucp	Reserved for the UUCP system; it does not currently use the <code>syslog</code> mechanism.																										
cron	The cron/at facility; <code>crontab(1)</code> , <code>at(1)</code> , <code>cron(1M)</code> , among others.																										
local0-7	Reserved for local use.																										
mark	For timestamp messages produced internally by <code>syslogd</code> .																										
*	An asterisk indicates all facilities except for the mark facility.																										
emerg	For panic conditions that would normally be broadcast to all users.																										

syslog.conf(4)

alert	For conditions that should be corrected immediately, such as a corrupted system database.
crit	For warnings about critical conditions, such as hard device errors.
err	For other errors.
warning	For warning messages.
notice	For conditions that are not error conditions, but may require special handling. A configuration entry with a <i>level</i> value of <i>notice</i> must appear on a separate line.
info	Informational messages.
debug	For messages that are normally used only when debugging a program.
none	Do not send messages from the indicated <i>facility</i> to the selected file. For example, a <i>selector</i> of * .debug;mail.none will send all messages <i>except</i> mail messages to the selected file.

The *action* field indicates where to forward the message. Values for this field can have one of four forms:

- A filename, beginning with a leading slash, which indicates that messages specified by the *selector* are to be written to the specified file. The file will be opened in append mode if it exists. If the file does not exist, logging will silently fail for this action.
- The name of a remote host, prefixed with an @, as with: @*server*, which indicates that messages specified by the *selector* are to be forwarded to the *syslogd* on the named host. The hostname "loghost" is the hostname given to the machine that will log *syslogd* messages. Every machine is "loghost" by default. See *hosts(4)*. It is also possible to specify one machine on a network to be "loghost" by making the appropriate host table entries. If the local machine is designated to be "loghost", then *syslogd* messages are written to the appropriate files. Otherwise, they are sent to the machine "loghost" on the network.
- A comma-separated list of usernames, which indicates that messages specified by the *selector* are to be written to the named users if they are logged in.
- An asterisk, which indicates that messages specified by the *selector* are to be written to all logged-in users.

Blank lines are ignored. Lines for which the first nonwhite character is a '#' are treated as comments.

EXAMPLES **EXAMPLE 1** A Sample Configuration File

With the following configuration file:

```

*.notice                /var/log/notice
mail.info               /var/log/notice
*.crit                 /var/log/critical
kern,mark.debug        /dev/console
kern.err               @server
*.emerg                *
*.alert                root,operator
*.alert;auth.warning   /var/log/auth

```

syslogd(1M) will log all mail system messages except debug messages and all notice (or higher) messages into a file named `/var/log/notice`. It logs all critical messages into `/var/log/critical`, and all kernel messages and 20-minute marks onto the system console.

Kernel messages of err (error) severity or higher are forwarded to the machine named `server`. Emergency messages are forwarded to all users. The users `root` and `operator` are informed of any alert messages. All messages from the authorization system of warning level or higher are logged in the file `/var/log/auth`.

FILES	<code>/var/log/notice</code>	log of all mail system messages (except debug messages) and all messages of notice level or higher
	<code>/var/log/critical</code>	log of all critical messages
	<code>/var/log/auth</code>	log of all messages from the authorization system of warning level or higher

system(4)

NAME	system – system configuration information file																														
DESCRIPTION	<p>The <i>system</i> file is used for customizing the operation of the operating system kernel. The recommended procedure is to preserve the original <i>system</i> file before modifying it.</p> <p>The <i>system</i> file contains commands which are read by the kernel during initialization and used to customize the operation of your system. These commands are useful for modifying the system's treatment of its loadable kernel modules.</p> <p>The syntax of the <i>system</i> file consists of a list of keyword/value pairs which are recognized by the system as valid commands. Comment lines must begin with an asterisk (*) or a hash mark (#) and end with a newline character. All commands are case-insensitive except where noted. A command line can be no more than 80 characters in length.</p> <p>Commands that modify the system's operation with respect to loadable kernel modules require you to specify the module type by listing the module's namespace. The following namespaces are currently supported on all platforms:</p> <table><tr><td>drv</td><td>Modules in this namespace are device drivers.</td></tr><tr><td>exec</td><td>Modules in this namespace are execution format modules. The following <i>exec</i> modules are currently provided:</td></tr><tr><td></td><td>Only on SPARC system:</td></tr><tr><td></td><td>aoutexec</td></tr><tr><td></td><td>Only on IA system:</td></tr><tr><td></td><td>coffexec</td></tr><tr><td></td><td>On SPARC and IA systems:</td></tr><tr><td></td><td>elfexec</td></tr><tr><td></td><td>intpexec</td></tr><tr><td></td><td>javaexec</td></tr></table> <tr><td>fs</td><td>These modules are filesystems.</td></tr> <tr><td>sched</td><td>These modules implement a process scheduling algorithm.</td></tr> <tr><td>strmod</td><td>These modules are STREAMS modules.</td></tr> <tr><td>sys</td><td>These modules implement loadable system-call modules.</td></tr> <tr><td>misc</td><td>These modules do not fit into any of the above categories, so are considered "miscellaneous" modules.</td></tr>	drv	Modules in this namespace are device drivers.	exec	Modules in this namespace are execution format modules. The following <i>exec</i> modules are currently provided:		Only on SPARC system:		aoutexec		Only on IA system:		coffexec		On SPARC and IA systems:		elfexec		intpexec		javaexec	fs	These modules are filesystems.	sched	These modules implement a process scheduling algorithm.	strmod	These modules are STREAMS modules.	sys	These modules implement loadable system-call modules.	misc	These modules do not fit into any of the above categories, so are considered "miscellaneous" modules.
drv	Modules in this namespace are device drivers.																														
exec	Modules in this namespace are execution format modules. The following <i>exec</i> modules are currently provided:																														
	Only on SPARC system:																														
	aoutexec																														
	Only on IA system:																														
	coffexec																														
	On SPARC and IA systems:																														
	elfexec																														
	intpexec																														
	javaexec																														
fs	These modules are filesystems.																														
sched	These modules implement a process scheduling algorithm.																														
strmod	These modules are STREAMS modules.																														
sys	These modules implement loadable system-call modules.																														
misc	These modules do not fit into any of the above categories, so are considered "miscellaneous" modules.																														

SPARC only:

dacf These modules provide rules and actions for device auto-configuration.
 tod These modules provide support for the time of day hardware.
 cpu These modules provide CPU-specific kernel routines.

A description of each of the supported commands follows:

`exclude:`
`<namespace>/<modulename>` Do not allow the listed loadable kernel module to be loaded. `exclude` commands are cumulative; the list of modules to `exclude` is created by combining every `exclude` entry in the `system` file.

`include:`
`<namespace>/<modulename>` Include the listed loadable kernel module. This is the system's default, so using `include` does not modify the system's operation. `include` commands are cumulative.

`forceload:`
`<namespace>/<modulename>` Force this kernel module to be loaded during kernel initialization. The default action is to automatically load the kernel module when its services are first accessed. `forceload` commands are cumulative.

`rootdev: <device name>` Set the root device to the listed value instead of using the default root device as supplied by the boot program.

`rootfs: <root filesystem type>` Set the root filesystem type to the listed value.

`moddir: <first module path>[[{, }<second ...>]...]` Set the search path for loadable kernel modules. This command operates very much like the `PATH` shell variable. Multiple directories to search can be listed together, delimited either by blank spaces or colons.

`set [<module>:]<symbol> {=, |, &} [~][-]<value>` Set an integer or character pointer in the kernel or in the selected kernel module to a new value. This command is used to change kernel and module parameters and thus modify the operation of your system. Assignment operations are not cumulative, whereas bitwise AND and OR operations are cumulative.

Operations that are supported for modifying integer variables are: simple assignment, inclusive bitwise OR, bitwise AND, one's complement, and negation. Variables in a specific loadable module can be targeted for modification by specifying the variable name prefixed with the kernel module name and a colon (:) separator. Values can be specified as hexadecimal (0x10), Octal (046), or Decimal (5).

system(4)

The only operation supported for modifying character pointers is simple assignment. Static string data such as character arrays cannot be modified using the `set` command. Use care and ensure that the variable you are modifying is in fact a character pointer. The `set` command is very powerful, and will likely cause problems if used carelessly. The entire command, including the quoted string, cannot exceed 80 characters. The following escape sequences are supported within the quoted string:

```
\n      (newline)
\t      (tab)
\b      (backspace)
```

EXAMPLES

EXAMPLE 1 A sample system file.

The following is a sample system file.

```
* Force the ELF exec kernel module to be loaded during kernel
* initialization. Execution type modules are in the exec namespace.
forceload: exec/elfexec
* Change the root device to /sbus@1,f8000000/esp@0,800000/sd@3,0:a.
* You can derive root device names from /devices.
* Root device names must be the fully expanded Open Boot Prom
* device name. This command is platform and configuration specific.
* This example uses the first partition (a) of the SCSI disk at
* SCSI target 3 on the esp host adapter in slot 0 (on board)
* of the SBus of the machine.
* Adapter unit-address 3,0 at sbus unit-address 0,800000.
rootdev: /sbus@1,f8000000/esp@0,800000/sd@3,0:a
* Set the filesystem type of the root to ufs. Note that
* the equal sign can be used instead of the colon.
rootfs:ufs
* Set the search path for kernel modules to look first in
* /usr/phil/mod_test for modules, then in /kernel/modules (the
* default) if not found. Useful for testing new modules.
* Note that you can delimit your module pathnames using
* colons instead of spaces: moddir:/newmodules:/kernel/modules
moddir:/usr/phil/mod_test /kernel/modules
* Set the configuration option {_POSIX_CHOWN_RESTRICTED} :
* This configuration option is enabled by default.
set rstchown = 1
* Disable the configuration option {_POSIX_CHOWN_RESTRICTED} :
set rstchown = 0
* Turn on debugging messages in the modules mydriver. This is useful
* during driver development.
set mydriver:debug = 1
* Bitwise AND the kernel variable "moddebug" with the
* one's complement of the hex value 0x880, and set
* "moddebug" to this new value.
set moddebug & ~0x880
* Demonstrate the cumulative effect of the SET
* bitwise AND/OR operations by further modifying "moddebug"
```

EXAMPLE 1 A sample `system` file. (Continued)

```
* by ORing it with 0x40.  
set moddebug | 0x40
```

SEE ALSO `boot(1M)`, `init(1M)`, `kernel(1M)`

WARNINGS Lines in the `system` file must be fewer than 80 characters in length.

Use care when modifying the `system` file; it modifies the operation of the kernel. If you preserved the original `system` file, you can boot using `boot -a`, which will ask you to specify the path to the saved file. This should allow the system to boot correctly. If you cannot locate a `system` file that will work, you may specify `/dev/null`. This acts as an empty `system` file, and the system will attempt to boot using its default settings.

NOTES The `/etc/system` file is read only once, at boot time.

telnetrc(4)

NAME	telnetrc – file for telnet default options
DESCRIPTION	<p>The <code>.telnetrc</code> file contains commands that are executed when a connection is established on a per-host basis. Each line in the file contains a host name, one or more spaces or tabs, and a <code>telnet(1)</code> command. The host name, <code>DEFAULT</code>, matches all hosts. Lines beginning with the pound sign (<code>#</code>) are interpreted as comments and therefore ignored. <code>telnet(1)</code> commands are case-insensitive to the contents of the <code>.telnetrc</code> file.</p> <p>The <code>.telnetrc</code> file is retrieved from each user's HOME directory.</p>
EXAMPLES	<p>EXAMPLE 1 A sample file.</p> <p>In the following example, a <code>.telnetrc</code> file executes the <code>telnet(1)</code> command, <code>toggle</code>:</p> <pre>weirdhost toggle crmod # Always export \$PRINTER DEFAULT environ export PRINTER</pre> <p>The lines in this file indicate that the <code>toggle</code> argument <code>crmod</code>, whose default value is "off" (or <code>FALSE</code>), should be enabled when connecting to the system <code>weirdhost</code>. In addition, the value of the environment variable <code>PRINTER</code> should be exported to all systems. In this case, the <code>DEFAULT</code> keyword is used in place of the host name.</p>
FILES	<code>\$HOME/.telnetrc</code>
SEE ALSO	<code>telnet(1)</code> , <code>in.telnetd(1M)</code> , <code>environ(5)</code>

NAME	term – format of compiled term file
SYNOPSIS	<code>/usr/share/lib/terminfo/?/*</code>
DESCRIPTION	<p>The <code>term</code> file is compiled from <code>terminfo(4)</code> source files using <code>tic(1M)</code>. Compiled files are organized in a directory hierarchy under the first letter of each terminal name. For example, the <code>vt100</code> file would have the pathname <code>/usr/lib/terminfo/v/vt100</code>. The default directory is <code>/usr/share/lib/terminfo</code>. Synonyms for the same terminal are implemented by multiple links to the same compiled file.</p> <p>The format has been chosen so that it is the same on all hardware. An 8-bit byte is assumed, but no assumptions about byte ordering or sign extension are made. Thus, these binary <code>terminfo</code> files can be transported to other hardware with 8-bit bytes.</p> <p>Short integers are stored in two 8-bit bytes. The first byte contains the least significant 8 bits of the value, and the second byte contains the most significant 8 bits. (Thus, the value represented is $256*second+first$.) The value <code>-1</code> is represented by <code>0377, 0377</code>, and the value <code>-2</code> is represented by <code>0376, 0377</code>; other negative values are illegal. The <code>-1</code> generally means that a capability is missing from this terminal. The <code>-2</code> means that the capability has been cancelled in the <code>terminfo</code> source and also is to be considered missing.</p> <p>The compiled file is created from the source file descriptions of the terminals (see the <code>-I</code> option of <code>infocmp</code>) by using the <code>terminfo</code> compiler, <code>tic</code>, and read by the routine <code>setupterm</code> (see <code>curses(3CURSES)</code>). The file is divided into six parts in the following order: the header, terminal names, boolean flags, numbers, strings, and string table.</p> <p>The header section begins the file six short integers in the format described below. These integers are:</p> <ol style="list-style-type: none"> 1. the magic number (octal <code>0432</code>); 2. the size, in bytes, of the names section; 3. the number of bytes in the boolean section 4. the number of short integers in the numbers section; 5. the number of offsets (short integers) in the strings section; 6. the size, in bytes, of the string table. <p>The terminal name section comes next. It contains the first line of the <code>terminfo</code> description, listing the various names for the terminal, separated by the bar (<code> </code>) character (see <code>term(5)</code>). The section is terminated with an ASCII NUL character.</p> <p>The terminal name section is followed by the Boolean section, number section, string section, and string table.</p> <p>The boolean flags section consists of one byte for each flag. This byte is either 0 or 1 as the flag is present or absent. The value of 2 means that the flag has been cancelled. The capabilities are in the same order as the file <code><term.h></code>.</p>

term(4)

Between the boolean flags section and the number section, a null byte is inserted, if necessary, to ensure that the number section begins on an even byte offset. All short integers are aligned on a short word boundary.

The numbers section is similar to the boolean flags section. Each capability takes up two bytes, and is stored as a short integer. If the value represented is -1 or -2 , the capability is taken to be missing.

The strings section is also similar. Each capability is stored as a short integer, in the format above. A value of -1 or -2 means the capability is missing. Otherwise, the value is taken as an offset from the beginning of the string table. Special characters in X or $\backslash c$ notation are stored in their interpreted form, not the printing representation. Padding information ($\$<nn>$) and parameter information ($\%x$) are stored intact in uninterpreted form.

The final section is the string table. It contains all the values of string capabilities referenced in the string section. Each string is null terminated.

Note that it is possible for `setupterm` to expect a different set of capabilities than are actually present in the file. Either the database may have been updated since `setupterm` has been recompiled (resulting in extra unrecognized entries in the file) or the program may have been recompiled more recently than the database was updated (resulting in missing entries). The routine `setupterm` must be prepared for both possibilities—this is why the numbers and sizes are included. Also, new capabilities must always be added at the end of the lists of boolean, number, and string capabilities.

As an example, here is terminal information on the AT&T Model 37 KSR terminal as output by the `infocmp -I tty37` command:

```
37|tty37|AT&T model 37 teletype,
  hc, os, xon,
  bel=^G, cr=\r, cub1=\b, cud1=\n, cuu1=\E7, hd=\E9,

terminfo(4)

NAME	terminfo – terminal and printer capability database
SYNOPSIS	<code>/usr/share/lib/terminfo/?/*</code>
DESCRIPTION	<p>terminfo is a database that describes the capabilities of devices such as terminals and printers. Devices are described in terminfo source files by specifying a set of capabilities, by quantifying certain aspects of the device, and by specifying character sequences that affect particular results. This database is often used by screen oriented applications such as vi and curses-based programs, as well as by some system commands such as ls and more. This usage allows them to work with a variety of devices without changes to the programs.</p> <p>terminfo descriptions are located in the directory pointed to by the environment variable TERMINFO or in /usr/share/lib/terminfo. terminfo descriptions are generated by tic(1M).</p> <p>terminfo source files consist of one or more device descriptions. Each description consists of a header (beginning in column 1) and one or more lines that list the features for that particular device. Every line in a terminfo source file must end in a comma (,). Every line in a terminfo source file except the header must be indented with one or more white spaces (either spaces or tabs).</p> <p>Entries in terminfo source files consist of a number of comma-separated fields. White space after each comma is ignored. Embedded commas must be escaped by using a backslash. Each device entry has the following format:</p> <pre>alias₁ alias₂ . . . alias_n fullname, capability₁, capability₂, . . . capability_n,</pre> <p>The first line, commonly referred to as the header line, must begin in column one and must contain at least two aliases separated by vertical bars. The last field in the header line must be the long name of the device and it may contain any string. Alias names must be unique in the terminfo database and they must conform to system file naming conventions (see tic(1M)); they cannot, for example, contain white space or slashes.</p> <p>Every device must be assigned a name, such as "vt100". Device names (except the long name) should be chosen using the following conventions. The name should not contain hyphens because hyphens are reserved for use when adding suffixes that indicate special modes.</p> <p>These special modes may be modes that the hardware can be in, or user preferences. To assign a special mode to a particular device, append a suffix consisting of a hyphen and an indicator of the mode to the device name. For example, the -w suffix means "wide mode"; when specified, it allows for a width of 132 columns instead of the</p>

standard 80 columns. Therefore, if you want to use a "vt100" device set to wide mode, name the device "vt100-w." Use the following suffixes where possible.

Suffix	Meaning	Example
-w	Wide mode (more than 80 columns)	5410-w
-am	With auto. margins (usually default)	vt100-am
-nam	Without automatic margins	vt100-nam
-n	Number of lines on the screen	2300-40
-na	No arrow keys (leave them in local)	c100-na
-np	Number of pages of memory	c100-4p
-rv	Reverse video	4415-rv

The terminfo reference manual page is organized in two sections:

- PART 1: DEVICE CAPABILITIES
- PART 2: PRINTER CAPABILITIES

PART 1: DEVICE CAPABILITIES

Capabilities in `terminfo` are of three types: Boolean capabilities (which show that a device has or does not have a particular feature), numeric capabilities (which quantify particular features of a device), and string capabilities (which provide sequences that can be used to perform particular operations on devices).

In the following table, a `Variable` is the name by which a C programmer accesses a capability (at the `terminfo` level). A `Capname` is the short name for a capability specified in the `terminfo` source file. It is used by a person updating the source file and by the `tput` command. A `Termcap Code` is a two-letter sequence that corresponds to the `termcap` capability name. (Note that `termcap` is no longer supported.)

Capability names have no real length limit, but an informal limit of five characters has been adopted to keep them short. Whenever possible, capability names are chosen to be the same as or similar to those specified by the ANSI X3.64-1979 standard. Semantics are also intended to match those of the ANSI standard.

All string capabilities listed below may have padding specified, with the exception of those used for input. Input capabilities, listed under the `Strings` section in the following tables, have names beginning with `key_`. The `#i` symbol in the description field of the following tables refers to the *i*th parameter.

terminfo(4)

TABLE 1 Booleans

Variable	Name	Code	Description
auto_left_margin	bw	bw	cub1 wraps from column 0 to last column
auto_right_margin	am	am	Terminal has automatic margins
back_color_erase	bce	be	Screen erased with background color
can_change	ccc	cc	Terminal can re-define existing color
ceol_standout_glitch	xhp	xs	Standout not erased by overwriting (hp)
col_addr_glitch	xhpa	YA	Only positive motion for hpa/mhpa caps
cpi_changes_res	cpix	YF	Changing character pitch changes resolution
cr_cancels_micro_mode	crxm	YB	Using <code>cr</code> turns off micro mode
dest_tabs_magic_sms0	xt	xt	Destructive tabs, magic sms0 char (t1061)
eat_newline_glitch	xenl	xn	Newline ignored after 80 columns (Concept)
erase_overstrike	eo	eo	Can erase overstrikes with a blank
generic_type	gn	gn	Generic line type (for example, dialup, switch)
hard_copy	hc	hc	Hardcopy terminal
hard_cursor	chts	HC	Cursor is hard to see
has_meta_key	km	km	Has a meta key (shift, sets parity bit)
has_print_wheel	daisy	YC	Printer needs operator to change character set
has_status_line	hs	hs	Has extra "status line"
hue_lightness_saturation	hls	hl	Terminal uses only HLS color notation (Tektronix)
insert_null_glitch	in	in	Insert mode distinguishes nulls
lpi_changes_res	lpix	YG	Changing line pitch changes resolution
memory_above	da	da	Display may be retained above the screen
memory_below	db	db	Display may be retained below the screen

TABLE 1 Booleans (Continued)

Variable	Name	Code	Description
move_insert_mode	mir	mi	Safe to move while in insert mode
move_standout_mode	msgr	ms	Safe to move in standout modes
needs_xon_xoff	nxon	nx	Padding won't work, xon/xoff required
no_esc_ctlc	xsbc	xb	Beehive (f1=escape, f2=ctrl C)
no_pad_char	npc	NP	Pad character doesn't exist
non_dest_scroll_region	ndscr	ND	Scrolling region is nondestructive
non_rev_rmcup	nrrmc	NR	smcup does not reverse rmcup
over_strike	os	os	Terminal overstrikes on hard-copy terminal
prtr_silent	mc5i	5i	Printer won't echo on screen
row_addr_glitch	xvpa	YD	Only positive motion for vpa/mvpa caps
semi_auto_right_margin	sam	YE	Printing in last column causes cr
status_line_esc_ok	eslok	es	Escape can be used on the status line
tilde_glitch	hz	hz	Hazeltine; can't print tilde (~)
transparent_underline	ul	ul	Underline character overstrikes
xon_xoff	xon	xo	Terminal uses xon/xoff handshaking

TABLE 2 Numbers

Variable	Name	Code	Description
bit_image_entwining	bitwin	Yo	Number of passes for each bit-map row
bit_image_type	bitype	Yp	Type of bit image device
buffer_capacity	bufsz	Ya	Number of bytes buffered before printing
buttons	btms	BT	Number of buttons on the mouse
columns	cols	co	Number of columns in a line
dot_horz_spacing	spinh	Yc	Spacing of dots horizontally in dots per inch
dot_vert_spacing	spinv	Yb	Spacing of pins vertically in pins per inch

terminfo(4)

TABLE 2 Numbers (Continued)

Variable	Name	Code	Description
init_tabs	it	it	Tabs initially every # spaces
label_height	lh	lh	Number of rows in each label
label_width	lw	lw	Number of columns in each label
lines	lines	li	Number of lines on a screen or a page
lines_of_memory	lm	lm	Lines of memory if > lines; 0 means varies
max_attributes	ma	ma	Maximum combined video attributes terminal can display
magic_cookie_glitch	xmc	sg	Number of blank characters left by smso or rmso
max_colors	colors	Co	Maximum number of colors on the screen
max_micro_address	maddr	Yd	Maximum value in micro..._address
max_micro_jump	mjump	Ye	Maximum value in parm..._micro
max_pairs	pairs	pa	Maximum number of color-pairs on the screen
maximum_windows	wnum	MW	Maximum number of definable windows
micro_char_size	mcs	Yf	Character step size when in micro mode
micro_line_size	mls	Yg	Line step size when in micro mode
no_color_video	ncv	NC	Video attributes that can't be used with colors
num_labels	nlab	NI	Number of labels on screen (start at 1)
number_of_pins	npins	Yh	Number of pins in print-head
output_res_char	orc	Yi	Horizontal resolution in units per character

TABLE 2 Numbers *(Continued)*

Variable	Name	Code	Description
output_res_line	orl	Yj	Vertical resolution in units per line
output_res_horz_inch	orhi	Yk	Horizontal resolution in units per inch
output_res_vert_inch	orvi	Yl	Vertical resolution in units per inch
padding_baud_rate	pb	pb	Lowest baud rate where padding needed
print_rate	cps	Ym	Print rate in characters per second
virtual_terminal	vt	vt	Virtual terminal number (system)
wide_char_size	widcs	Yn	Character step size when in double wide mode
width_status_line	wsl	ws	Number of columns in status line

TABLE 3 Strings

Variable	Name	Code	Description
acs_chars	acsc	ac	Graphic charset pairs aAbBcC
alt_scancode_esc	scesa	S8	Alternate escape for scancode emulation (default is for vt100)
back_tab	cbt	bt	Back tab
bell	bel	bl	Audible signal (bell)
bit_image_carriage_return	bicr	Yv	Move to beginning of same row (use tparm)
bit_image_newline	binel	Zz	Move to next row of the bit image (use tparm)
bit_image_repeat	birep	Zy	Repeat bit-image cell #1 #2 times (use tparm)
carriage_return	cr	cr	Carriage return

terminfo(4)

TABLE 3 Strings (Continued)

Variable	Name	Code	Description
change_char_pitch	cpi	ZA	Change number of characters per inch
change_line_pitch	lpi	ZB	Change number of lines per inch
change_res_horz	chr	ZC	Change horizontal resolution
change_res_vert	cvr	ZD	Change vertical resolution
change_scroll_region	csr	cs	Change to lines #1 through #2 (vt100)
char_padding	rmp	rP	Like ip but when in replace mode
char_set_names	csnm	Zy	List of character set names
clear_all_tabs	tbc	ct	Clear all tab stops
clear_margins	mgc	MC	Clear all margins (top, bottom, and sides)
clear_screen	clear	cl	Clear screen and home cursor
clr_bol	el1	cb	Clear to beginning of line, inclusive
clr_eol	el	ce	Clear to end of line
clr_eos	ed	cd	Clear to end of display
code_set_init	csin	ci	Init sequence for multiple codesets
color_names	colorm	Yw	Give name for color #1
column_address	hpa	ch	Horizontal position absolute
command_character	cmdch	CC	Terminal settable cmd character in prototype
create_window	cwin	CW	Define win #1 to go from #2,#3 to #4,#5
cursor_address	cup	cm	Move to row #1 col #2
cursor_down	cud1	do	Down one line
cursor_home	home	ho	Home cursor (if no cup)
cursor_invisible	civis	vi	Make cursor invisible
cursor_left	cub1	le	Move left one space.
cursor_mem_address	mrcup	CM	Memory relative cursor addressing

TABLE 3 Strings (Continued)

Variable	Name	Code	Description
cursor_normal	cnorm	ve	Make cursor appear normal (undo vs/vi)
cursor_right	cuf1	nd	Non-destructive space (cursor or carriage right)
cursor_to_ll	ll	ll	Last line, first column (if no cup)
cursor_up	cuu1	up	Upline (cursor up)
cursor_visible	cvvis	vs	Make cursor very visible
define_bit_image_region	defbi	Yx	Define rectangular bit-image region (use tparm)
define_char	defc	ZE	Define a character in a character set*
delete_character	dch1	dc	Delete character
delete_line	dl1	dl	Delete line
device_type	devt	dv	Indicate language/codeset support
dial_phone	dial	DI	Dial phone number #1
dis_status_line	dsl	ds	Disable status line
display_clock	dclk	DK	Display time-of-day clock
display_pc_char	dispc	S1	Display PC character
down_half_line	hd	hd	Half-line down (forward 1/2 linefeed)
ena_acs	enacs	eA	Enable alternate character set
end_bit_image_region	endbi	Yy	End a bit-image region (use tparm)
enter_alt_charset_mode	smacs	as	Start alternate character set
enter_am_mode	smam	SA	Turn on automatic margins
enter_blink_mode	blink	mb	Turn on blinking
enter_bold_mode	bold	md	Turn on bold (extra bright) mode
enter_ca_mode	smcup	ti	String to begin programs that use cup
enter_delete_mode	smdc	dm	Delete mode (enter)

terminfo(4)

TABLE 3 Strings (Continued)

Variable	Name	Code	Description
enter_dim_mode	dim	mh	Turn on half-bright mode
enter_doublewide_mode	swidm	ZF	Enable double wide printing
enter_draft_quality	sdrfq	ZG	Set draft quality print mode
enter_insert_mode	smir	im	Insert mode (enter)
enter_italics_mode	sitm	ZH	Enable italics
enter_leftward_mode	slm	ZI	Enable leftward carriage motion
enter_micro_mode	smicm	ZJ	Enable micro motion capabilities
enter_near_letter_quality	snlq	ZK	Set near-letter quality print
enter_normal_quality	snrmq	ZL	Set normal quality print
enter_pc_charset_mode	smpch	S2	Enter PC character display mode
enter_protected_mode	prot	mp	Turn on protected mode
enter_reverse_mode	rev	mr	Turn on reverse video mode
enter_scancode_mode	smsc	S4	Enter PC scancode mode
enter_secure_mode	invis	mk	Turn on blank mode (characters invisible)
enter_shadow_mode	sshm	ZM	Enable shadow printing
enter_standout_mode	smso	so	Begin standout mode
enter_subscript_mode	ssubm	ZN	Enable subscript printing
enter_superscript_mode	ssupm	ZO	Enable superscript printing
enter_underline_mode	smul	us	Start underscore mode
enter_upward_mode	sum	ZP	Enable upward carriage motion mode
enter_xon_mode	smxon	SX	Turn on xon/xoff handshaking
erase_chars	ech	ec	Erase #1 characters
exit_alt_charset_mode	rmacs	ae	End alternate character set
exit_am_mode	rmam	RA	Turn off automatic margins
exit_attribute_mode	sgr0	me	Turn off all attributes

TABLE 3 Strings (Continued)

Variable	Name	Code	Description
exit_ca_mode	rmcup	te	String to end programs that use cup
exit_delete_mode	rmdc	ed	End delete mode
exit_doublewide_mode	rwidm	ZQ	Disable double wide printing
exit_insert_mode	rmir	ei	End insert mode
exit_italics_mode	ritm	ZR	Disable italics
exit_leftward_mode	rlm	ZS	Enable rightward (normal) carriage motion
exit_micro_mode	rmicm	ZT	Disable micro motion capabilities
exit_pc_charset_mode	rmpch	S3	Disable PC character display mode
exit_scancode_mode	rmsc	S5	Disable PC scancode mode
exit_shadow_mode	rshm	ZU	Disable shadow printing
exit_standout_mode	rmso	se	End standout mode
exit_subscript_mode	rsubm	ZV	Disable subscript printing
exit_superscript_mode	rsupm	ZW	Disable superscript printing
exit_underline_mode	rmul	ue	End underscore mode
exit_upward_mode	rum	ZX	Enable downward (normal) carriage motion
exit_xon_mode	rmxon	RX	Turn off xon/xoff handshaking
fixed_pause	pause	PA	Pause for 2-3 seconds
flash_hook	hook	fh	Flash the switch hook
flash_screen	flash	vb	Visible bell (may not move cursor)
form_feed	ff	ff	Hardcopy terminal page eject
from_status_line	fsl	fs	Return from status line
get_mouse	getm	Gm	Curses should get button events
goto_window	wingo	WG	Go to window #1
hangup	hup	HU	Hang-up phone
init_1string	is1	i1	Terminal or printer initialization string

terminfo(4)

TABLE 3 Strings (Continued)

Variable	Name	Code	Description
init_2string	is2	is	Terminal or printer initialization string
init_3string	is3	i3	Terminal or printer initialization string
init_file	if	if	Name of initialization file
init_prog	ipro	iP	Path name of program for initialization
initialize_color	initc	Ic	Initialize the definition of color
initialize_pair	initp	Ip	Initialize color-pair
insert_character	ich1	ic	Insert character
insert_line	il1	al	Add new blank line
insert_padding	ip	ip	Insert pad after character inserted

The “key_” strings are sent by specific keys. The “key_” descriptions include the macro, defined in `< curses.h >`, for the code returned by the `curses` routine `getch` when the key is pressed (see `curs_getch(3CURSES)`).

TABLE 4 key_ Strings

Variable	Name	Code	Description
key_a1	ka1	K1	KEY_A1, upper left of keypad
key_a3	ka3	K3	KEY_A3, upper right of keypad
key_b2	kb2	K2	KEY_B2, center of keypad
key_backspace	kbs	kb	KEY_BACKSPACE, sent by backspace key
key_beg	kbeg	@1	KEY_BEG, sent by beg(inning) key
key_btab	kcbt	kB	KEY_BTAB, sent by back-tab key
key_c1	kc1	K4	KEY_C1, lower left of keypad
key_c3	kc3	K5	KEY_C3, lower right of keypad
key_cancel	kcan	@2	KEY_CANCEL, sent by cancel key
key_catab	ktbc	ka	KEY_CATAB, sent by clear-all-tabs key

TABLE 4 key_Strings (Continued)

Variable	Name	Code	Description
key_clear	kclr	kC	KEY_CLEAR, sent by clear-screen or erase key
key_close	kclo	@3	KEY_CLOSE, sent by close key
key_command	kcmd	@4	KEY_COMMAND, sent by cmd (command) key
key_copy	kcpy	@5	KEY_COPY, sent by copy key
key_create	kcrt	@6	KEY_CREATE, sent by create key
key_ctab	kctab	kt	KEY_CTAB, sent by clear-tab key
key_dc	kdch1	kD	KEY_DC, sent by delete-character key
key_dl	kdl1	kL	KEY_DL, sent by delete-line key
key_down	kcud1	kd	KEY_DOWN, sent by terminal down-arrow key
key_eic	krmir	kM	KEY_EIC, sent by rmir or smir in insert mode
key_end	kend	@7	KEY_END, sent by end key
key_enter	kent	@8	KEY_ENTER, sent by enter/send key
key_eol	kel	kE	KEY_EOL, sent by clear-to-end-of-line key
key_eos	ked	kS	KEY_EOS, sent by clear-to-end-of-screen key
key_exit	kext	@9	KEY_EXIT, sent by exit key
key_f0	kf0	k0	KEY_F(0), sent by function key f0
key_f1	kf1	k1	KEY_F(1), sent by function key f1
key_f2	kf2	k2	KEY_F(2), sent by function key f2
key_f3	kf3	k3	KEY_F(3), sent by function key f3
key_fB	kf4	k4	KEY_F(4), sent by function key fB
key_f5	kf5	k5	KEY_F(5), sent by function key f5

terminfo(4)

TABLE 4 key_Strings (Continued)

Variable	Name	Code	Description
key_f6	kf6	k6	KEY_F (6) , sent by function key f6
key_f7	kf7	k7	KEY_F (7) , sent by function key f7
key_f8	kf8	k8	KEY_F (8) , sent by function key f8
key_f9	kf9	k9	KEY_F (9) , sent by function key f9
key_f10	kf10	k;	KEY_F (10) , sent by function key f10
key_f11	kf11	F1	KEY_F (11) , sent by function key f11
key_f12	kf12	F2	KEY_F (12) , sent by function key f12
key_f13	kf13	F3	KEY_F (13) , sent by function key f13
key_f14	kf14	F4	KEY_F (14) , sent by function key f14
key_f15	kf15	F5	KEY_F (15) , sent by function key f15
key_f16	kf16	F6	KEY_F (16) , sent by function key f16
key_f17	kf17	F7	KEY_F (17) , sent by function key f17
key_f18	kf18	F8	KEY_F (18) , sent by function key f18
key_f19	kf19	F9	KEY_F (19) , sent by function key f19
key_f20	kf20	FA	KEY_F (20) , sent by function key f20
key_f21	kf21	FB	KEY_F (21) , sent by function key f21
key_f22	kf22	FC	KEY_F (22) , sent by function key f22
key_f23	kf23	FD	KEY_F (23) , sent by function key f23
key_f24	kf24	FE	KEY_F (24) , sent by function key f24

TABLE 4 key_Strings (Continued)

Variable	Name	Code	Description
key_f25	kf25	FF	KEY_F(25), sent by function key f25
key_f26	kf26	FG	KEY_F(26), sent by function key f26
key_f27	kf27	FH	KEY_F(27), sent by function key f27
key_f28	kf28	FI	KEY_F(28), sent by function key f28
key_f29	kf29	FJ	KEY_F(29), sent by function key f29
key_f30	kf30	FK	KEY_F(30), sent by function key f30
key_f31	kf31	FL	KEY_F(31), sent by function key f31
key_f32	kf32	FM	KEY_F(32), sent by function key f32
key_f33	kf33	FN	KEY_F(33), sent by function key f33
key_f34	kf34	FO	KEY_F(34), sent by function key f34
key_f35	kf35	FP	KEY_F(35), sent by function key f35
key_f36	kf36	FQ	KEY_F(36), sent by function key f36
key_f37	kf37	FR	KEY_F(37), sent by function key f37
key_f38	kf38	FS	KEY_F(38), sent by function key f38
key_f39	kf39	FT	KEY_F(39), sent by function key f39
key_fb0	kf40	FU	KEY_F(40), sent by function key fb0
key_fb1	kf41	FV	KEY_F(41), sent by function key fb1
key_fb2	kf42	FW	KEY_F(42), sent by function key fb2

terminfo(4)

TABLE 4 key_Strings (Continued)

Variable	Name	Code	Description
key_fb3	kf43	FX	KEY_F (43), sent by function key fb3
key_fb4	kf44	FY	KEY_F (44), sent by function key fb4

Types of Capabilities in the Sample Entry

The sample entry shows the formats for the three types of terminfo capabilities listed: Boolean, numeric, and string. All capabilities specified in the terminfo source file must be followed by commas, including the last capability in the source file. In terminfo source files, capabilities are referenced by their capability names (as shown in the previous tables).

Boolean capabilities are specified simply by their comma separated cap names.

Numeric capabilities are followed by the character '#' and then a positive integer value. Thus, in the sample, cols (which shows the number of columns available on a device) is assigned the value 80 for the AT&T 610. (Values for numeric capabilities may be specified in decimal, octal, or hexadecimal, using normal C programming language conventions.)

Finally, string-valued capabilities such as el (clear to end of line sequence) are listed by a two- to five-character capname, an '=', and a string ended by the next occurrence of a comma. A delay in milliseconds may appear anywhere in such a capability, preceded by \$ and enclosed in angle brackets, as in el=\EK\$<3>. Padding characters are supplied by tput. The delay can be any of the following: a number, a number followed by an asterisk, such as 5*, a number followed by a slash, such as 5/, or a number followed by both, such as 5*/. A '*' shows that the padding required is proportional to the number of lines affected by the operation, and the amount given is the per-affected-unit padding required. (In the case of insert characters, the factor is still the number of lines affected. This is always 1 unless the device has in and the software uses it.) When a '*' is specified, it is sometimes useful to give a delay of the form 3.5 to specify a delay per unit to tenths of milliseconds. (Only one decimal place is allowed.)

A `'/'` indicates that the padding is mandatory. If a device has `xon` defined, the padding information is advisory and will only be used for cost estimates or when the device is in raw mode. Mandatory padding will be transmitted regardless of the setting of `xon`. If padding (whether advisory or mandatory) is specified for `bel` or `flash`, however, it will always be used, regardless of whether `xon` is specified.

`terminfo` offers notation for encoding special characters. Both `\E` and `\e` map to an ESCAPE character, `^x` maps to a control `x` for any appropriate `x`, and the sequences `\n`, `\l`, `\r`, `\t`, `\b`, `\f`, and `\s` give a newline, linefeed, return, tab, backspace, formfeed, and space, respectively. Other escapes include: `\^` for caret (^); `\\` for backslash (\); `\,` for comma (,); `\:` for colon (:); and `\0` for null. (`\0` will actually produce `\200`, which does not terminate a string but behaves as a null character on most devices, providing CS7 is specified. (See `stty(1)`). Finally, characters may be given as three octal digits after a backslash (for example, `\123`).

Sometimes individual capabilities must be commented out. To do this, put a period before the capability name. For example, see the second `ind` in the example above. Note that capabilities are defined in a left-to-right order and, therefore, a prior definition will override a later definition.

Preparing Descriptions

The most effective way to prepare a device description is by imitating the description of a similar device in `terminfo` and building up a description gradually, using partial descriptions with `vi` to check that they are correct. Be aware that a very unusual device may expose deficiencies in the ability of the `terminfo` file to describe it or the inability of `vi` to work with that device. To test a new device description, set the environment variable `TERMINFO` to the pathname of a directory containing the compiled description you are working on and programs will look there rather than in `/usr/share/lib/terminfo`. To get the padding for insert-line correct (if the device manufacturer did not document it) a severe test is to comment out `xon`, edit a large file at 9600 baud with `vi`, delete 16 or so lines from the middle of the screen, and then press the `u` key several times quickly. If the display is corrupted, more padding is usually needed. A similar test can be used for insert-character.

Section 1-1: Basic Capabilities

The number of columns on each line for the device is given by the `cols` numeric capability. If the device has a screen, then the number of lines on the screen is given by the `lines` capability. If the device wraps around to the beginning of the next line when it reaches the right margin, then it should have the `am` capability. If the terminal can clear its screen, leaving the cursor in the home position, then this is given by the `clear` string capability. If the terminal overstrikes (rather than clearing a position when a character is struck over) then it should have the `os` capability. If the device is a printing terminal, with no soft copy unit, specify both `hc` and `os`. If there is a way to move the cursor to the left edge of the current row, specify this as `cr`. (Normally this will be carriage return, control M.) If there is a way to produce an audible signal (such as a bell or a beep), specify it as `bel`. If, like most devices, the device uses the `xon-xoff` flow-control protocol, specify `xon`.

If there is a way to move the cursor one position to the left (such as backspace), that capability should be given as `cub1`. Similarly, sequences to move to the right, up, and

terminfo(4)

down should be given as `cuf1`, `cuu1`, and `cud1`, respectively. These local cursor motions must not alter the text they pass over; for example, you would not normally use `"cuf1=\s"` because the space would erase the character moved over.

A very important point here is that the local cursor motions encoded in `terminfo` are undefined at the left and top edges of a screen terminal. Programs should never attempt to backspace around the left edge, unless `bw` is specified, and should never attempt to go up locally off the top. To scroll text up, a program goes to the bottom left corner of the screen and sends the `ind` (index) string.

To scroll text down, a program goes to the top left corner of the screen and sends the `ri` (reverse index) string. The strings `ind` and `ri` are undefined when not on their respective corners of the screen.

Parameterized versions of the scrolling sequences are `indn` and `rin`. These versions have the same semantics as `ind` and `ri`, except that they take one parameter and scroll the number of lines specified by that parameter. They are also undefined except at the appropriate edge of the screen.

The `am` capability tells whether the cursor sticks at the right edge of the screen when text is output, but this does not necessarily apply to a `cuf1` from the last column. Backward motion from the left edge of the screen is possible only when `bw` is specified. In this case, `cub1` will move to the right edge of the previous row. If `bw` is not given, the effect is undefined. This is useful for drawing a box around the edge of the screen, for example. If the device has switch selectable automatic margins, `am` should be specified in the `terminfo` source file. In this case, initialization strings should turn on this option, if possible. If the device has a command that moves to the first column of the next line, that command can be given as `ne1` (newline). It does not matter if the command clears the remainder of the current line, so if the device has no `cr` and `lf` it may still be possible to craft a working `ne1` out of one or both of them.

These capabilities suffice to describe hardcopy and screen terminals. Thus the AT&T 5320 hardcopy terminal is described as follows:

```
5320|att5320|AT&T 5320 hardcopy terminal,
  am, hc, os,
  cols#132,
  bel=^G, cr=\r, cub1=\b, cnd1=\n,
  dch1=\E[P, dll1=\E[M,
  ind=\n,
```

while the Lear Siegler ADM-3 is described as

```
adm3 | lsi adm3,
  am, bel=^G, clear=^Z, cols#80, cr=^M, cub1=^H,
  cud1=^J, ind=^J, lines#24,
```

Section 1-2: Parameterized Strings

Cursor addressing and other strings requiring parameters are described by a parameterized string capability, with `printf`-like escapes (`%x`) in it. For example, to address the cursor, the `cup` capability is given, using two parameters: the row and column to address to. (Rows and columns are numbered from zero and refer to the

physical screen visible to the user, not to any unseen memory.) If the terminal has memory relative cursor addressing, that can be indicated by `mr cup`.

The parameter mechanism uses a stack and special `%` codes to manipulate the stack in the manner of Reverse Polish Notation (postfix). Typically a sequence will push one of the parameters onto the stack and then print it in some format. Often more complex operations are necessary. Operations are in postfix form with the operands in the usual order. That is, to subtract 5 from the first parameter, one would use `%p1%{5}%-`.

The `%` encodings have the following meanings:

```
%%
  outputs '%'

% [[:]flags][width[.precision]][doxXs]
  as in printf, flags are [-+#] and space

%c
  print pop gives %c

%p [1-9]
  push ith parm

%P [a-z]
  set dynamic variable [a-z] to pop

%g [a-z]
  get dynamic variable [a-z] and push it

%P [A-Z]
  set static variable [a-z] to pop

%g [A-Z]
  get static variable [a-z] and push it

%' c'
  push char constant c

%{nn}
  push decimal constant nn

%l
  push strlen(pop)

%+ %- %* %/ %m
  arithmetic (%m is mod): push(pop integer2 op pop integer1)

%& %| %^
  bit operations: push(pop integer2 op pop integer1)

%= %> %<
  logical operations: push(pop integer2 op pop integer1)

%A %O
  logical operations: and, or
```

terminfo(4)

%! %~

unary operations: push(op pop)

%i

(for ANSI terminals) add 1 to first parm, if one parm present, or first two parms, if more than one parm present

?? expr %t *thenpart* %e *elsepart* %;

if-then-else, %e *elsepart* is optional; else-if's are possible ala Algol 68: ?? c₁ %t b₁ %e c₂ %t b₂ %e c₃ %t b₃ %e c₄ %t b₄ %e b₅%; c_i are conditions, b_i are bodies.

If the "--" flag is used with "[%doxXs]", then a colon (:) must be placed between the "%" and the "--" to differentiate the flag from the binary "%-" operator, for example "%:-16.16s".

Consider the Hewlett-Packard 2645, which, to get to row 3 and column 12, needs to be sent `\E&a12c03Y` padded for 6 milliseconds. Note that the order of the rows and columns is inverted here, and that the row and column are zero-padded as two digits. Thus its cup capability is: `cup=\E&a%p2%2.2dc%p1%2.2dY$<6>`

The Micro-Term ACT-IV needs the current row and column sent preceded by a ^T, with the row and column simply encoded in binary, "`cup=^T%p1%c%p2%c`". Devices that use "%c" need to be able to backspace the cursor (`cub1`), and to move the cursor up one line on the screen (`cuu1`). This is necessary because it is not always safe to transmit `\n`, `^D`, and `\r`, as the system may change or discard them. (The library routines dealing with `terminfo` set tty modes so that tabs are never expanded, so `\t` is safe to send. This turns out to be essential for the Ann Arbor 4080.)

A final example is the LSI ADM-3a, which uses row and column offset by a blank character, thus "`cup=\E=%p1%'\s' %+%c%p2%'\s' %+%c`". After sending "`\E=`", this pushes the first parameter, pushes the ASCII value for a space (32), adds them (pushing the sum on the stack in place of the two previous values), and outputs that value as a character. Then the same is done for the second parameter. More complex arithmetic is possible using the stack.

Section 1-3: Cursor Motions

If the terminal has a fast way to home the cursor (to very upper left corner of screen) then this can be given as `home`; similarly a fast way of getting to the lower left-hand corner can be given as `ll`; this may involve going up with `cuu1` from the home position, but a program should never do this itself (unless `ll` does) because it can make no assumption about the effect of moving up from the home position. Note that the home position is the same as addressing to (0,0): to the top left corner of the screen, not of memory. (Thus, the `\EH` sequence on Hewlett-Packard terminals cannot be used for `home` without losing some of the other features on the terminal.)

If the device has row or column absolute-cursor addressing, these can be given as single parameter capabilities `hpa` (horizontal position absolute) and `vpa` (vertical position absolute). Sometimes these are shorter than the more general two-parameter sequence (as with the Hewlett-Packard 2645) and can be used in preference to `cup`. If there are parameterized local motions (for example, move *n* spaces to the right) these

can be given as `cud`, `cub`, `cuf`, and `cuu` with a single parameter indicating how many spaces to move. These are primarily useful if the device does not have `cup`, such as the Tektronix 4025.

If the device needs to be in a special mode when running a program that uses these capabilities, the codes to enter and exit this mode can be given as `smcup` and `rmcup`. This arises, for example, from terminals, such as the Concept, with more than one page of memory. If the device has only memory relative cursor addressing and not screen relative cursor addressing, a one screen-sized window must be fixed into the device for cursor addressing to work properly. This is also used for the Tektronix 4025, where `smcup` sets the command character to be the one used by `terminfo`. If the `smcup` sequence will not restore the screen after an `rmcup` sequence is output (to the state prior to outputting `rmcup`), specify `nrrmc`.

Section 1-4: Area Clears

If the terminal can clear from the current position to the end of the line, leaving the cursor where it is, this should be given as `e1`. If the terminal can clear from the beginning of the line to the current position inclusive, leaving the cursor where it is, this should be given as `e11`. If the terminal can clear from the current position to the end of the display, then this should be given as `ed`. `ed` is only defined from the first column of a line. (Thus, it can be simulated by a request to delete a large number of lines, if a true `ed` is not available.)

Section 1-5: Insert/Delete Line

If the terminal can open a new blank line before the line where the cursor is, this should be given as `i11`; this is done only from the first position of a line. The cursor must then appear on the newly blank line. If the terminal can delete the line which the cursor is on, then this should be given as `d11`; this is done only from the first position on the line to be deleted. Versions of `i11` and `d11` which take a single parameter and insert or delete that many lines can be given as `i1` and `d1`.

If the terminal has a settable destructive scrolling region (like the VT100) the command to set this can be described with the `csr` capability, which takes two parameters: the top and bottom lines of the scrolling region. The cursor position is, alas, undefined after using this command. It is possible to get the effect of insert or delete line using this command — the `sc` and `rc` (save and restore cursor) commands are also useful. Inserting lines at the top or bottom of the screen can also be done using `ri` or `ind` on many terminals without a true insert/delete line, and is often faster even on terminals with those features.

To determine whether a terminal has destructive scrolling regions or non-destructive scrolling regions, create a scrolling region in the middle of the screen, place data on the bottom line of the scrolling region, move the cursor to the top line of the scrolling region, and do a reverse index (`ri`) followed by a delete line (`d11`) or index (`ind`). If the data that was originally on the bottom line of the scrolling region was restored into the scrolling region by the `d11` or `ind`, then the terminal has non-destructive scrolling regions. Otherwise, it has destructive scrolling regions. Do not specify `csr` if the terminal has non-destructive scrolling regions, unless `ind`, `ri`, `indn`, `rin`, `d1`, and `d11` all simulate destructive scrolling.

terminfo(4)

**Section 1-6:
Insert/Delete
Character**

If the terminal has the ability to define a window as part of memory, which all commands affect, it should be given as the parameterized string `wind`. The four parameters are the starting and ending lines in memory and the starting and ending columns in memory, in that order.

If the terminal can retain display memory above, then the `da` capability should be given; if display memory can be retained below, then `db` should be given. These indicate that deleting a line or scrolling a full screen may bring non-blank lines up from below or that scrolling back with `ri` may bring down non-blank lines.

There are two basic kinds of intelligent terminals with respect to insert/delete character operations which can be described using `terminfo`. The most common insert/delete character operations affect only the characters on the current line and shift characters off the end of the line rigidly. Other terminals, such as the Concept 100 and the Perkin Elmer Owl, make a distinction between typed and untyped blanks on the screen, shifting upon an insert or delete only to an untyped blank on the screen which is either eliminated, or expanded to two untyped blanks. You can determine the kind of terminal you have by clearing the screen and then typing text separated by cursor motions. Type "`abc def`" using local cursor motions (not spaces) between the `abc` and the `def`. Then position the cursor before the `abc` and put the terminal in insert mode. If typing characters causes the rest of the line to shift rigidly and characters to fall off the end, then your terminal does not distinguish between blanks and untyped positions. If the `abc` shifts over to the `def` which then move together around the end of the current line and onto the next as you insert, you have the second type of terminal, and should give the capability `in`, which stands for "insert null." While these are two logically separate attributes (one line versus multiline insert mode, and special treatment of untyped spaces) we have seen no terminals whose insert mode cannot be described with the single attribute.

`terminfo` can describe both terminals that have an insert mode and terminals which send a simple sequence to open a blank position on the current line. Give as `smir` the sequence to get into insert mode. Give as `rmir` the sequence to leave insert mode. Now give as `ich1` any sequence needed to be sent just before sending the character to be inserted. Most terminals with a true insert mode will not give `ich1`; terminals that send a sequence to open a screen position should give it here. (If your terminal has both, insert mode is usually preferable to `ich1`. Do not give both unless the terminal actually requires both to be used in combination.) If post-insert padding is needed, give this as a number of milliseconds padding in `ip` (a string option). Any other sequence which may need to be sent after an insert of a single character may also be given in `ip`. If your terminal needs both to be placed into an 'insert mode' and a special code to precede each inserted character, then both `smir/rmir` and `ich1` can be given, and both will be used. The `ich` capability, with one parameter, `n`, will insert `n` blanks.

If padding is necessary between characters typed while not in insert mode, give this as a number of milliseconds padding in `rmp`.

It is occasionally necessary to move around while in insert mode to delete characters on the same line (for example, if there is a tab after the insertion position). If your terminal allows motion while in insert mode you can give the capability `mir` to speed up inserting in this case. Omitting `mir` will affect only speed. Some terminals (notably Datamedia's) must not have `mir` because of the way their insert mode works.

Finally, you can specify `dch1` to delete a single character, `dch` with one parameter, *n*, to delete *n* characters, and delete mode by giving `smdc` and `rmdc` to enter and exit delete mode (any mode the terminal needs to be placed in for `dch1` to work).

A command to erase *n* characters (equivalent to outputting *n* blanks without moving the cursor) can be given as `ech` with one parameter.

Section 1-7: Highlighting, Underlining, and Visible Bells

Your device may have one or more kinds of display attributes that allow you to highlight selected characters when they appear on the screen. The following display modes (shown with the names by which they are set) may be available: a blinking screen (`blink`), bold or extra-bright characters (`bold`), dim or half-bright characters (`dim`), blanking or invisible text (`invis`), protected text (`prot`), a reverse-video screen (`rev`), and an alternate character set (`smacs` to enter this mode and `rmacs` to exit it). (If a command is necessary before you can enter alternate character set mode, give the sequence in `enacs` or "enable alternate-character-set" mode.) Turning on any of these modes singly may or may not turn off other modes.

`sgr0` should be used to turn off all video enhancement capabilities. It should always be specified because it represents the only way to turn off some capabilities, such as `dim` or `blink`.

You should choose one display method as *standout mode* and use it to highlight error messages and other kinds of text to which you want to draw attention. Choose a form of display that provides strong contrast but that is easy on the eyes. (We recommend reverse-video plus half-bright or reverse-video alone.) The sequences to enter and exit standout mode are given as `smso` and `rmso`, respectively. If the code to change into or out of standout mode leaves one or even two blank spaces on the screen, as the TVI 912 and Telera 1061 do, then `xmc` should be given to tell how many spaces are left.

Sequences to begin underlining and end underlining can be specified as `smul` and `rmul`, respectively. If the device has a sequence to underline the current character and to move the cursor one space to the right (such as the Micro-Term MIME), this sequence can be specified as `uc`.

Terminals with the "magic cookie" glitch (`xmc`) deposit special "cookies" when they receive mode-setting sequences, which affect the display algorithm rather than having extra bits for each character. Some terminals, such as the Hewlett-Packard 2621, automatically leave standout mode when they move to a new line or the cursor is addressed. Programs using standout mode should exit standout mode before moving the cursor or sending a newline, unless the `msgx` capability, asserting that it is safe to move in standout mode, is present.

terminfo(4)

If the terminal has a way of flashing the screen to indicate an error quietly (a bell replacement), then this can be given as `flash`; it must not move the cursor. A good flash can be done by changing the screen into reverse video, pad for 200 ms, then return the screen to normal video.

If the cursor needs to be made more visible than normal when it is not on the bottom line (to make, for example, a non-blinking underline into an easier to find block or blinking underline) give this sequence as `cvvis`. The boolean `chts` should also be given. If there is a way to make the cursor completely invisible, give that as `civis`. The capability `cnorm` should be given which undoes the effects of either of these modes.

If your terminal generates underlined characters by using the underline character (with no special sequences needed) even though it does not otherwise overstrike characters, then you should specify the capability `ul`. For devices on which a character overstriking another leaves both characters on the screen, specify the capability `os`. If overstrikes are erasable with a blank, then this should be indicated by specifying `eo`.

If there is a sequence to set arbitrary combinations of modes, this should be given as `sgr` (set attributes), taking nine parameters. Each parameter is either 0 or non-zero, as the corresponding attribute is on or off. The nine parameters are, in order: standout, underline, reverse, blink, dim, bold, blank, protect, alternate character set. Not all modes need to be supported by `sgr`; only those for which corresponding separate attribute commands exist should be supported. For example, let's assume that the terminal in question needs the following escape sequences to turn on various modes.

tparm		
parameter	attribute	escape sequence
	none	\E[0m
p1	standout	\E[0;4;7m
p2	underline	\E[0;3m
p3	reverse	\E[0;4m
p4	blink	\E[0;5m
p5	dim	\E[0;7m
p6	bold	\E[0;3;4m
p7	invis	\E[0;8m
p8	protect	not available
p9	altcharset	^O (off) ^N (on)

Note that each escape sequence requires a 0 to turn off other modes before turning on its own mode. Also note that, as suggested above, *standout* is set up to be the combination of *reverse* and *dim*. Also, because this terminal has no *bold* mode, *bold* is set up as the combination of *reverse* and *underline*. In addition, to allow combinations, such as *underline+blink*, the sequence to use would be `\E[0;3;5m`. The terminal doesn't have *protect* mode, either, but that cannot be simulated in any way, so `p8` is ignored. The *altcharset* mode is different in that it is either `^O` or `^N`, depending on whether it is off or on. If all modes were to be turned on, the sequence would be `\E[0;3;4;5;7;8m^N`.

Now look at when different sequences are output. For example, `;3` is output when either `p2` or `p6` is true, that is, if either *underline* or *bold* modes are turned on. Writing out the above sequences, along with their dependencies, gives the following:

sequence	when to output	terminfo translation
<code>\E[0</code>	always	<code>\E[0</code>
<code>;3</code>	if <code>p2</code> or <code>p6</code>	<code>%%?%p2%p6% %t;3%;</code>
<code>;4</code>	if <code>p1</code> or <code>p3</code> or <code>p6</code>	<code>%%?%p1%p3% %p6% %t;4%;</code>
<code>;5</code>	if <code>p4</code>	<code>%%?%p4%t;5%;</code>
<code>;7</code>	if <code>p1</code> or <code>p5</code>	<code>%%?%p1%p5% %t;7%;</code>
<code>;8</code>	if <code>p7</code>	<code>%%?%p7%t;8%;</code>
<code>m</code>	always	<code>m</code>
<code>^N</code> or <code>^O</code>	if <code>p9</code> <code>^N</code> , else <code>^O</code>	<code>%%?%p9%t^N%e^O%;</code>

Putting this all together into the `sgr` sequence gives:

```
sgr=\E[0%%?%p2%p6%| %t;3%;%%?%p1%p3%| %p6%
| %t;4%;%%?%p5%t;5%;%%?%p1%p5%| %t;7%;%%?%p7%t;8%;m%%?%p9%t^N%e^O%;,
```

Remember that `sgr` and `sgr0` must always be specified.

Section 1-8: Keypad

If the device has a keypad that transmits sequences when the keys are pressed, this information can also be specified. Note that it is not possible to handle devices where the keypad only works in local (this applies, for example, to the unshifted Hewlett-Packard 2621 keys). If the keypad can be set to transmit or not transmit, specify these sequences as `smkx` and `rmkx`. Otherwise the keypad is assumed to always transmit.

The sequences sent by the left arrow, right arrow, up arrow, down arrow, and home keys can be given as `kcub1`, `kcuf1`, `kcuu1`, `kcud1`, and `khome`, respectively. If there are function keys such as `f0`, `f1`, ..., `f63`, the sequences they send can be specified as `kf0`, `kf1`, ..., `kf63`. If the first 11 keys have labels other than the default `f0`

terminfo(4)

through `f10`, the labels can be given as `lf0`, `lf1`, . . . , `lf10`. The codes transmitted by certain other special keys can be given: `kll` (home down), `kbs` (backspace), `ktbc` (clear all tabs), `kctab` (clear the tab stop in this column), `kclr` (clear screen or erase key), `kdch1` (delete character), `kdll` (delete line), `krmir` (exit insert mode), `kel` (clear to end of line), `ked` (clear to end of screen), `kich1` (insert character or enter insert mode), `kill` (insert line), `knp` (next page), `kpp` (previous page), `kind` (scroll forward/down), `kri` (scroll backward/up), `khts` (set a tab stop in this column). In addition, if the keypad has a 3 by 3 array of keys including the four arrow keys, the other five keys can be given as `ka1`, `ka3`, `kb2`, `kc1`, and `kc3`. These keys are useful when the effects of a 3 by 3 directional pad are needed. Further keys are defined above in the capabilities list.

Strings to program function keys can be specified as `pfkey`, `pfloc`, and `pfx`. A string to program screen labels should be specified as `pln`. Each of these strings takes two parameters: a function key identifier and a string to program it with. `pfkey` causes pressing the given key to be the same as the user typing the given string; `pfloc` causes the string to be executed by the terminal in local mode; and `pfx` causes the string to be transmitted to the computer. The capabilities `nlab`, `lw` and `lh` define the number of programmable screen labels and their width and height. If there are commands to turn the labels on and off, give them in `smln` and `rmln`. `smln` is normally output after one or more `pln` sequences to make sure that the change becomes visible.

Section 1-9: Tabs and Initialization

If the device has hardware tabs, the command to advance to the next tab stop can be given as `ht` (usually control I). A “backtab” command that moves leftward to the next tab stop can be given as `cbt`. By convention, if tty modes show that tabs are being expanded by the computer rather than being sent to the device, programs should not use `ht` or `cbt` (even if they are present) because the user may not have the tab stops properly set. If the device has hardware tabs that are initially set every *n* spaces when the device is powered up, the numeric parameter `it` is given, showing the number of spaces the tabs are set to. This is normally used by `tput init` (see `tput(1)`) to determine whether to set the mode for hardware tab expansion and whether to set the tab stops. If the device has tab stops that can be saved in nonvolatile memory, the `terminfo` description can assume that they are properly set. If there are commands to set and clear tab stops, they can be given as `tbc` (clear all tab stops) and `hts` (set a tab stop in the current column of every row).

Other capabilities include: `is1`, `is2`, and `is3`, initialization strings for the device; `ipro`, the path name of a program to be run to initialize the device; and `if`, the name of a file containing long initialization strings. These strings are expected to set the device into modes consistent with the rest of the `terminfo` description. They must be sent to the device each time the user logs in and be output in the following order: run the program `ipro`; output `is1`; output `is2`; set the margins using `mgc`, `smg1` and `smgr`; set the tabs using `tbc` and `hts`; print the file `if`; and finally output `is3`. This is usually done using the `init` option of `tput`.

Most initialization is done with `is2`. Special device modes can be set up without duplicating strings by putting the common sequences in `is2` and special cases in `is1`

and `is3`. Sequences that do a reset from a totally unknown state can be given as `rs1`, `rs2`, `rf`, and `rs3`, analogous to `is1`, `is2`, `is3`, and `if`. (The method using files, `if` and `rf`, is used for a few terminals, from `/usr/share/lib/tabset/*`; however, the recommended method is to use the initialization and reset strings.) These strings are output by `tput reset`, which is used when the terminal gets into a wedged state. Commands are normally placed in `rs1`, `rs2`, `rs3`, and `rf` only if they produce annoying effects on the screen and are not necessary when logging in. For example, the command to set a terminal into 80-column mode would normally be part of `is2`, but on some terminals it causes an annoying glitch on the screen and is not normally needed because the terminal is usually already in 80-column mode.

If a more complex sequence is needed to set the tabs than can be described by using `tbc` and `hts`, the sequence can be placed in `is2` or `if`.

Any margin can be cleared with `mgc`. (For instructions on how to specify commands to set and clear margins, see "Margins" below under "PRINTER CAPABILITIES.")

Section 1-10: Delays

Certain capabilities control padding in the `tty` driver. These are primarily needed by hard-copy terminals, and are used by `tput init` to set `tty` modes appropriately. Delays embedded in the capabilities `cr`, `ind`, `cub1`, `ff`, and `tab` can be used to set the appropriate delay bits to be set in the `tty` driver. If `pb` (padding baud rate) is given, these values can be ignored at baud rates below the value of `pb`.

Section 1-11: Status Lines

If the terminal has an extra "status line" that is not normally used by software, this fact can be indicated. If the status line is viewed as an extra line below the bottom line, into which one can cursor address normally (such as the Heathkit h19's 25th line, or the 24th line of a VT100 which is set to a 23-line scrolling region), the capability `hs` should be given. Special strings that go to a given column of the status line and return from the status line can be given as `ts1` and `fs1`. (`fs1` must leave the cursor position in the same place it was before `ts1`. If necessary, the `sc` and `rc` strings can be included in `ts1` and `fs1` to get this effect.) The capability `ts1` takes one parameter, which is the column number of the status line the cursor is to be moved to.

If escape sequences and other special commands, such as `tab`, work while in the status line, the flag `eslok` can be given. A string which turns off the status line (or otherwise erases its contents) should be given as `ds1`. If the terminal has commands to save and restore the position of the cursor, give them as `sc` and `rc`. The status line is normally assumed to be the same width as the rest of the screen, for example, `cols`. If the status line is a different width (possibly because the terminal does not allow an entire line to be loaded) the width, in columns, can be indicated with the numeric parameter `ws1`.

Section 1-12: Line Graphics

If the device has a line drawing alternate character set, the mapping of glyph to character would be given in `acsc`. The definition of this string is based on the alternate character set used in the DEC VT100 terminal, extended slightly with some characters from the AT&T 4410v1 terminal.

terminfo(4)

Glyph Name	vt100+ Character
arrow pointing right	+
arrow pointing left	,
arrow pointing down	.
solid square block	0
lantern symbol	I
arrow pointing up	-
diamond	'
checker board (stipple)	a
degree symbol	f
plus/minus	g
board of squares	h
lower right corner	j
upper right corner	k
upper left corner	l
lower left corner	m
plus	n
scan line 1	o
horizontal line	q
scan line 9	s
left tee	t
right tee	u
bottom tee	v
top tee	w
vertical line	x
bullet	~

The best way to describe a new device's line graphics set is to add a third column to the above table with the characters for the new device that produce the appropriate glyph when the device is in the alternate character set mode. For example,

Glyph Name	vt100+ Char	New tty Char
upper left corner	l	R
lower left corner	m	F
upper right corner	k	T
lower right corner	j	G
horizontal line	q	,
vertical line	x	.

Now write down the characters left to right, as in `"acsc=1RmFkTjGq\,x."`.

In addition, `terminfo` allows you to define multiple character sets. See Section 2-5 for details.

Section 1-13: Color Manipulation

Let us define two methods of color manipulation: the Tektronix method and the HP method. The Tektronix method uses a set of `N` predefined colors (usually 8) from which a user can select "current" foreground and background colors. Thus a terminal can support up to `N` colors mixed into `N*N` color-pairs to be displayed on the screen at the same time. When using an HP method the user cannot define the foreground independently of the background, or vice-versa. Instead, the user must define an entire color-pair at once. Up to `M` color-pairs, made from `2*M` different colors, can be defined this way. Most existing color terminals belong to one of these two classes of terminals.

The numeric variables `colors` and `pairs` define the number of colors and color-pairs that can be displayed on the screen at the same time. If a terminal can change the definition of a color (for example, the Tektronix 4100 and 4200 series terminals), this should be specified with `ccc` (can change color). To change the definition of a color (Tektronix 4200 method), use `initc` (initialize color). It requires four arguments: color number (ranging from 0 to `colors-1`) and three RGB (red, green, and blue) values or three HLS colors (Hue, Lightness, Saturation). Ranges of RGB and HLS values are terminal dependent.

Tektronix 4100 series terminals only use HLS color notation. For such terminals (or dual-mode terminals to be operated in HLS mode) one must define a boolean variable `hls`; that would instruct the curses `init_color` routine to convert its RGB arguments to HLS before sending them to the terminal. The last three arguments to the `initc` string would then be HLS values.

If a terminal can change the definitions of colors, but uses a color notation different from RGB and HLS, a mapping to either RGB or HLS must be developed.

To set current foreground or background to a given color, use `setaf` (set ANSI foreground) and `setab` (set ANSI background). They require one parameter: the number of the color. To initialize a color-pair (HP method), use `initp` (initialize pair).

terminfo(4)

It requires seven parameters: the number of a color-pair (range=0 to pairs-1), and six RGB values: three for the foreground followed by three for the background. (Each of these groups of three should be in the order RGB.) When `initc` or `initp` are used, RGB or HLS arguments should be in the order "red, green, blue" or "hue, lightness, saturation"), respectively. To make a color-pair current, use `scp` (set color-pair). It takes one parameter, the number of a color-pair.

Some terminals (for example, most color terminal emulators for PCs) erase areas of the screen with current background color. In such cases, `bce` (background color erase) should be defined. The variable `op` (original pair) contains a sequence for setting the foreground and the background colors to what they were at the terminal start-up time. Similarly, `oc` (original colors) contains a control sequence for setting all colors (for the Tektronix method) or color-pairs (for the HP method) to the values they had at the terminal start-up time.

Some color terminals substitute color for video attributes. Such video attributes should not be combined with colors. Information about these video attributes should be packed into the `ncv` (no color video) variable. There is a one-to-one correspondence between the nine least significant bits of that variable and the video attributes. The following table depicts this correspondence.

Attribute	Bit Position	Decimal Value
A_STANDOUT	0	1
A_UNDERLINE	1	2
A_REVERSE	2	4
A_BLINK	3	8
A_DIM	4	16
A_BOLD	5	32
A_INVIS	6	64
A_PROTECT	7	128
A_ALTCHARSET	8	256

When a particular video attribute should not be used with colors, the corresponding `ncv` bit should be set to 1; otherwise it should be set to zero. To determine the information to pack into the `ncv` variable, you must add together the decimal values corresponding to those attributes that cannot coexist with colors. For example, if the terminal uses colors to simulate reverse video (bit number 2 and decimal value 4) and bold (bit number 5 and decimal value 32), the resulting value for `ncv` will be 36 (4 + 32).

**Section 1-14:
Miscellaneous**

If the terminal requires other than a null (zero) character as a pad, then this can be given as `pad`. Only the first character of the `pad` string is used. If the terminal does not have a pad character, specify `npc`.

If the terminal can move up or down half a line, this can be indicated with `hu` (half-line up) and `hd` (half-line down). This is primarily useful for superscripts and subscripts on hardcopy terminals. If a hardcopy terminal can eject to the next page (form feed), give this as `ff` (usually control L).

If there is a command to repeat a given character a given number of times (to save time transmitting a large number of identical characters) this can be indicated with the parameterized string `rep`. The first parameter is the character to be repeated and the second is the number of times to repeat it. Thus, `tparam(repeat_char, 'x', 10)` is the same as `xxxxxxxxxx`.

If the terminal has a settable command character, such as the Tektronix 4025, this can be indicated with `cmdch`. A prototype command character is chosen which is used in all capabilities. This character is given in the `cmdch` capability to identify it. The following convention is supported on some systems: If the environment variable `CC` exists, all occurrences of the prototype character are replaced with the character in `CC`.

Terminal descriptions that do not represent a specific kind of known terminal, such as `switch`, `dialup`, `patch`, and `network`, should include the `gn` (generic) capability so that programs can complain that they do not know how to talk to the terminal. (This capability does not apply to *virtual* terminal descriptions for which the escape sequences are known.) If the terminal is one of those supported by the system virtual terminal protocol, the terminal number can be given as `vt`. A line-turn-around sequence to be transmitted before doing reads should be specified in `rfi`.

If the device uses `xon/xoff` handshaking for flow control, give `xon`. Padding information should still be included so that routines can make better decisions about costs, but actual pad characters will not be transmitted. Sequences to turn on and off `xon/xoff` handshaking may be given in `smxon` and `rmxon`. If the characters used for handshaking are not `^S` and `^Q`, they may be specified with `xonc` and `xoffc`.

If the terminal has a "meta key" which acts as a shift key, setting the 8th bit of any character transmitted, this fact can be indicated with `km`. Otherwise, software will assume that the 8th bit is parity and it will usually be cleared. If strings exist to turn this "meta mode" on and off, they can be given as `smm` and `rmm`.

If the terminal has more lines of memory than will fit on the screen at once, the number of lines of memory can be indicated with `lm`. A value of `lm#0` indicates that the number of lines is not fixed, but that there is still more memory than fits on the screen.

Media copy strings which control an auxiliary printer connected to the terminal can be given as `mc0`: print the contents of the screen, `mc4`: turn off the printer, and `mc5`: turn on the printer. When the printer is on, all text sent to the terminal will be sent to the printer. A variation, `mc5p`, takes one parameter, and leaves the printer on for as many

terminfo(4)

characters as the value of the parameter, then turns the printer off. The parameter should not exceed 255. If the text is not displayed on the terminal screen when the printer is on, specify `mc5i` (silent printer). All text, including `mc4`, is transparently passed to the printer while an `mc5p` is in effect.

**Section 1-15:
Special Cases**

The working model used by `terminfo` fits most terminals reasonably well. However, some terminals do not completely match that model, requiring special support by `terminfo`. These are not meant to be construed as deficiencies in the terminals; they are just differences between the working model and the actual hardware. They may be unusual devices or, for some reason, do not have all the features of the `terminfo` model implemented.

Terminals that cannot display tilde (~) characters, such as certain Hazeltine terminals, should indicate `hz`.

Terminals that ignore a linefeed immediately after an `am` wrap, such as the Concept 100, should indicate `xenl`. Those terminals whose cursor remains on the right-most column until another character has been received, rather than wrapping immediately upon receiving the right-most character, such as the VT100, should also indicate `xenl`.

If `e1` is required to get rid of standout (instead of writing normal text on top of it), `xhp` should be given.

Those Teleray terminals whose tabs turn all characters moved over to blanks, should indicate `xt` (destructive tabs). This capability is also taken to mean that it is not possible to position the cursor on top of a "magic cookie." Therefore, to erase standout mode, it is necessary, instead, to use delete and insert line.

Those Beehive Superbee terminals which do not transmit the escape or control-C characters, should specify `xsb`, indicating that the `f1` key is to be used for escape and the `f2` key for control C.

**Section 1-16:
Similar Terminals**

If there are two very similar terminals, one can be defined as being just like the other with certain exceptions. The string capability `use` can be given with the name of the similar terminal. The capabilities given before `use` override those in the terminal type invoked by `use`. A capability can be canceled by placing `xx@` to the left of the capability definition, where `xx` is the capability. For example, the entry

```
att4424-2|Teletype4424 in display function group ii,  
rev@, sgr@, smul@, use=att4424,
```

defines an AT&T4424 terminal that does not have the `rev`, `sgr`, and `smul` capabilities, and hence cannot do highlighting. This is useful for different modes for a terminal, or for different user preferences. More than one `use` capability may be given.

**PART 2: PRINTER
CAPABILITIES**

The `terminfo` database allows you to define capabilities of printers as well as terminals. To find out what capabilities are available for printers as well as for terminals, see the two lists under "DEVICE CAPABILITIES" that list capabilities by variable and by capability name.

**Section 2-1:
Rounding Values**

Because parameterized string capabilities work only with integer values, we recommend that `terminfo` designers create strings that expect numeric values that have been rounded. Application designers should note this and should always round values to the nearest integer before using them with a parameterized string capability.

**Section 2-2: Printer
Resolution**

A printer's resolution is defined to be the smallest spacing of characters it can achieve. In general printers have independent resolution horizontally and vertically. Thus the vertical resolution of a printer can be determined by measuring the smallest achievable distance between consecutive printing baselines, while the horizontal resolution can be determined by measuring the smallest achievable distance between the left-most edges of consecutive printed, identical, characters.

All printers are assumed to be capable of printing with a uniform horizontal and vertical resolution. The view of printing that `terminfo` currently presents is one of printing inside a uniform matrix: All characters are printed at fixed positions relative to each "cell" in the matrix; furthermore, each cell has the same size given by the smallest horizontal and vertical step sizes dictated by the resolution. (The cell size can be changed as will be seen later.)

Many printers are capable of "proportional printing," where the horizontal spacing depends on the size of the character last printed. `terminfo` does not make use of this capability, although it does provide enough capability definitions to allow an application to simulate proportional printing.

A printer must not only be able to print characters as close together as the horizontal and vertical resolutions suggest, but also of "moving" to a position an integral multiple of the smallest distance away from a previous position. Thus printed characters can be spaced apart a distance that is an integral multiple of the smallest distance, up to the length or width of a single page.

Some printers can have different resolutions depending on different "modes." In "normal mode," the existing `terminfo` capabilities are assumed to work on columns and lines, just like a video terminal. Thus the old `lines` capability would give the length of a page in lines, and the `cols` capability would give the width of a page in columns. In "micro mode," many `terminfo` capabilities work on increments of lines and columns. With some printers the micro mode may be concomitant with normal mode, so that all the capabilities work at the same time.

**Section 2-3:
Specifying Printer
Resolution**

The printing resolution of a printer is given in several ways. Each specifies the resolution as the number of smallest steps per distance:

Specification of Printer Resolution
Characteristic Number of Smallest Steps

```
orhi  Steps per inch horizontally
orvi  Steps per inch vertically
orc   Steps per column
orl   Steps per line
```

terminfo(4)

When printing in normal mode, each character printed causes movement to the next column, except in special cases described later; the distance moved is the same as the per-column resolution. Some printers cause an automatic movement to the next line when a character is printed in the rightmost position; the distance moved vertically is the same as the per-line resolution. When printing in micro mode, these distances can be different, and may be zero for some printers.

Specification of Printer Resolution Automatic Motion after Printing

Normal Mode:

orc Steps moved horizontally
orl Steps moved vertically

Micro Mode:

mcs Steps moved horizontally
mls Steps moved vertically

Some printers are capable of printing wide characters. The distance moved when a wide character is printed in normal mode may be different from when a regular width character is printed. The distance moved when a wide character is printed in micro mode may also be different from when a regular character is printed in micro mode, but the differences are assumed to be related: If the distance moved for a regular character is the same whether in normal mode or micro mode ($mcs=orc$), then the distance moved for a wide character is also the same whether in normal mode or micro mode. This doesn't mean the normal character distance is necessarily the same as the wide character distance, just that the distances don't change with a change in normal to micro mode. However, if the distance moved for a regular character is different in micro mode from the distance moved in normal mode ($mcs<orc$), the micro mode distance is assumed to be the same for a wide character printed in micro mode, as the table below shows.

Specification of Printer Resolution Automatic Motion after Printing Wide Character

Normal Mode or Micro Mode ($mcs = orc$):

sp
widcs Steps moved horizontally

Micro Mode ($mcs < orc$):

mcs Steps moved horizontally

There may be control sequences to change the number of columns per inch (the character pitch) and to change the number of lines per inch (the line pitch). If these are used, the resolution of the printer changes, but the type of change depends on the printer:

Specification of Printer Resolution
Changing the Character/Line Pitches

`cpi` Change character pitch
`cpix` If set, `cpi` changes `orhi`, otherwise changes
`orc`
`lpi` Change line pitch
`lpix` If set, `lpi` changes `orvi`, otherwise changes
`orl`
`chr` Change steps per column
`cvr` Change steps per line

The `cpi` and `lpi` string capabilities are each used with a single argument, the pitch in columns (or characters) and lines per inch, respectively. The `chr` and `cvr` string capabilities are each used with a single argument, the number of steps per column and line, respectively.

Using any of the control sequences in these strings will imply a change in some of the values of `orc`, `orhi`, `orl`, and `orvi`. Also, the distance moved when a wide character is printed, `widcs`, changes in relation to `orc`. The distance moved when a character is printed in micro mode, `mcs`, changes similarly, with one exception: if the distance is 0 or 1, then no change is assumed (see items marked with * in the following table).

Programs that use `cpi`, `lpi`, `chr`, or `cvr` should recalculate the printer resolution (and should recalculate other values— see "Effect of Changing Printing Resolution" under "Dot-Mapped Graphics").

Specification of Printer Resolution
Effects of Changing the Character/Line Pitches

Before	After
--------	-------

Using `cpi` with `cpix` clear:

```
$bold orhi '$ orhi
$bold orc '$ $bold orc = bold orhi over V sub italic cpi$
```

Using `cpi` with `cpix` set:

```
$bold orhi '$ $bold orhi = bold orc cdot V sub italic cpi$
$bold orc '$ $bold orc$
```

Using `lpi` with `lpix` clear:

```
$bold orvi '$ $bold orvi$
$bold orl '$ $bold orl = bold orvi over V sub italic lpi$
```

terminfo(4)

Using `lpi` with `lpix` set:
`$bold orvi '$ $bold orvi = bold orl cdot V sub italic lpi$`
`$bold orl '$ $bold orl$`

Using `chr`:
`$bold orhi '$ $bold orhi$`
`$bold orc '$ $V sub italic chr$`

Using `cvr`:
`$bold orvi '$ $bold orvi$`
`$bold orl '$ $V sub italic cvr$`

Using `cpi` or `chr`:
`$bold widcs '$ $bold widcs = bold {widcs ' } bold orc over { bold {orc ' } }$`
`$bold mcs '$ $bold mcs = bold {mcs ' } bold orc over { bold {orc ' } }$`

`$V sub italic cpi$`, `$V sub italic lpi$`, `$V sub italic chr$`, and `$V sub italic cvr$` are the arguments used with `cpi`, `lpi`, `chr`, and `cvr`, respectively. The prime marks (`'`) indicate the old values.

Section 2-4: Capabilities that Cause Movement

In the following descriptions, “movement” refers to the motion of the “current position.” With video terminals this would be the cursor; with some printers this is the carriage position. Other printers have different equivalents. In general, the current position is where a character would be displayed if printed.

`terminfo` has string capabilities for control sequences that cause movement a number of full columns or lines. It also has equivalent string capabilities for control sequences that cause movement a number of smallest steps.

String Capabilities for Motion

`mcub1` Move 1 step left
`mcuf1` Move 1 step right
`mceu1` Move 1 step up
`mcud1` Move 1 step down
`mcub` Move N steps left
`mcuf` Move N steps right
`mceu` Move N steps up
`mcud` Move N steps down
`mhpa` Move N steps from the left
`mvpa` Move N steps from the top

The latter six strings are each used with a single argument, *N*.

Sometimes the motion is limited to less than the width or length of a page. Also, some printers don't accept absolute motion to the left of the current position. `terminfo` has capabilities for specifying these limits.

Limits to Motion

mjump Limit on use of mcub1, mcuf1, mctu1, mcud1
 maddr Limit on use of mhp, mvpa
 xhpa If set, hpa and mhp can't move left
 xvpa If set, vpa and mvpa can't move up

If a printer needs to be in a "micro mode" for the motion capabilities described above to work, there are string capabilities defined to contain the control sequence to enter and exit this mode. A boolean is available for those printers where using a carriage return causes an automatic return to normal mode.

Entering/Exiting Micro Mode

smicm Enter micro mode
 rmicm Exit micro mode
 crxm Using cr exits micro mode

The movement made when a character is printed in the rightmost position varies among printers. Some make no movement, some move to the beginning of the next line, others move to the beginning of the same line. `terminfo` has boolean capabilities for describing all three cases.

What Happens After Character
Printed in Rightmost Position

sam Automatic move to beginning of same line

Some printers can be put in a mode where the normal direction of motion is reversed. This mode can be especially useful when there are no capabilities for leftward or upward motion, because those capabilities can be built from the motion reversal capability and the rightward or downward motion capabilities. It is best to leave it up to an application to build the leftward or upward capabilities, though, and not enter them in the `terminfo` database. This allows several reverse motions to be strung together without intervening wasted steps that leave and reenter reverse mode.

Entering/Exiting Reverse Modes

slm Reverse sense of horizontal motions
 rlm Restore sense of horizontal motions
 sum Reverse sense of vertical motions
 rum Restore sense of vertical motions

While sense of horizontal motions reversed:

mcub1 Move 1 step right
 mcuf1 Move 1 step left
 mcub Move N steps right
 mcuf Move N steps left

terminfo(4)

cub1 Move 1 column right
cuf1 Move 1 column left
cub Move N columns right
cuf Move N columns left

While sense of vertical motions reversed:

mceu1 Move 1 step down
mcud1 Move 1 step up
mceu Move N steps down
mcud Move N steps up
cuu1 Move 1 line down
cud1 Move 1 line up
cuu Move N lines down
cud Move N lines up

The reverse motion modes should not affect the `mvpa` and `mhpa` absolute motion capabilities. The reverse vertical motion mode should, however, also reverse the action of the line “wrapping” that occurs when a character is printed in the right-most position. Thus printers that have the standard `terminfo` capability `am` defined should experience motion to the beginning of the previous line when a character is printed in the right-most position under reverse vertical motion mode.

The action when any other motion capabilities are used in reverse motion modes is not defined; thus, programs must exit reverse motion modes before using other motion capabilities.

Two miscellaneous capabilities complete the list of new motion capabilities. One of these is needed for printers that move the current position to the beginning of a line when certain control characters, such as “line-feed” or “form-feed,” are used. The other is used for the capability of suspending the motion that normally occurs after printing a character.

Miscellaneous Motion Strings

docr List of control characters causing cr
zerom Prevent auto motion after printing next single character

Margins

`terminfo` provides two strings for setting margins on terminals: one for the left and one for the right margin. Printers, however, have two additional margins, for the top and bottom margins of each page. Furthermore, some printers require not using motion strings to move the current position to a margin and then fixing the margin there, but require the specification of where a margin should be regardless of the current position. Therefore `terminfo` offers six additional strings for defining margins with printers.

Setting Margins

smgl Set left margin at current column

```

smgr  Set right margin at current column
smgb  Set bottom margin at current line
smgt  Set top margin at current line
smgbp Set bottom margin at line N
smglp Set left margin at column N
smgrp Set right margin at column N
smgtp Set top margin at line N

```

The last four strings are used with one or more arguments that give the position of the margin or margins to set. If both of `smglp` and `smgrp` are set, each is used with a single argument, *N*, that gives the column number of the left and right margin, respectively. If both of `smgtp` and `smgbp` are set, each is used to set the top and bottom margin, respectively: `smgtp` is used with a single argument, *N*, the line number of the top margin; however, `smgbp` is used with two arguments, *N* and *M*, that give the line number of the bottom margin, the first counting from the top of the page and the second counting from the bottom. This accommodates the two styles of specifying the bottom margin in different manufacturers' printers. When coding a `terminfo` entry for a printer that has a settable bottom margin, only the first or second parameter should be used, depending on the printer. When writing an application that uses `smgbp` to set the bottom margin, both arguments must be given.

If only one of `smglp` and `smgrp` is set, then it is used with two arguments, the column number of the left and right margins, in that order. Likewise, if only one of `smgtp` and `smgbp` is set, then it is used with two arguments that give the top and bottom margins, in that order, counting from the top of the page. Thus when coding a `terminfo` entry for a printer that requires setting both left and right or top and bottom margins simultaneously, only one of `smglp` and `smgrp` or `smgtp` and `smgbp` should be defined; the other should be left blank. When writing an application that uses these string capabilities, the pairs should be first checked to see if each in the pair is set or only one is set, and should then be used accordingly.

In counting lines or columns, line zero is the top line and column zero is the left-most column. A zero value for the second argument with `smgbp` means the bottom line of the page.

All margins can be cleared with `mgc`.

Shadows, Italics, Wide Characters

Five new sets of strings describe the capabilities printers have of enhancing printed text.

Enhanced Printing

```

sshm  Enter shadow-printing mode
rshm  Exit shadow-printing mode
sitm  Enter italicizing mode
ritm  Exit italicizing mode
swidm Enter wide character mode
rwidm Exit wide character mode

```

terminfo(4)

`ssupm` Enter superscript mode
`rsum` Exit superscript mode
`supcs` List of characters available as superscripts
`ssubm` Enter subscript mode
`rsubm` Exit subscript mode
`subcs` List of characters available as subscripts

If a printer requires the `sshm` control sequence before every character to be shadow-printed, the `rshm` string is left blank. Thus programs that find a control sequence in `sshm` but none in `rshm` should use the `sshm` control sequence before every character to be shadow-printed; otherwise, the `sshm` control sequence should be used once before the set of characters to be shadow-printed, followed by `rshm`. The same is also true of each of the `sitm/ritm`, `swidm/rwidm`, `ssupm/rsum`, and `ssubm/rsubm` pairs.

Note that `terminfo` also has a capability for printing emboldened text (`bold`). While shadow printing and emboldened printing are similar in that they “darken” the text, many printers produce these two types of print in slightly different ways. Generally, emboldened printing is done by overstriking the same character one or more times. Shadow printing likewise usually involves overstriking, but with a slight movement up and/or to the side so that the character is “fatter.”

It is assumed that enhanced printing modes are independent modes, so that it would be possible, for instance, to shadow print italicized subscripts.

As mentioned earlier, the amount of motion automatically made after printing a wide character should be given in `widcs`.

If only a subset of the printable ASCII characters can be printed as superscripts or subscripts, they should be listed in `supcs` or `subcs` strings, respectively. If the `ssupm` or `ssubm` strings contain control sequences, but the corresponding `supcs` or `subcs` strings are empty, it is assumed that all printable ASCII characters are available as superscripts or subscripts.

Automatic motion made after printing a superscript or subscript is assumed to be the same as for regular characters. Thus, for example, printing any of the following three examples will result in equivalent motion:

`B`_{*i*} `B`_{*i*} `B`^{*i*}

Note that the existing `msgr` boolean capability describes whether motion control sequences can be used while in “standout mode.” This capability is extended to cover the enhanced printing modes added here. `msgr` should be set for those printers that accept any motion control sequences without affecting shadow, italicized, widened, superscript, or subscript printing. Conversely, if `msgr` is not set, a program should end these modes before attempting any motion.

Section 2-5: Alternate Character Sets

In addition to allowing you to define line graphics (described in Section 1-12), `terminfo` lets you define alternate character sets. The following capabilities cover printers and terminals with multiple selectable or definable character sets.

Alternate Character Sets

```
scs   Select character set N
scsd  Start definition of character set N, M characters
defc  Define character A, B dots wide, descender D
rcsd  End definition of character set N
csnm  List of character set names
daisy Printer has manually changed print-wheels
```

The `scs`, `rcsd`, and `csnm` strings are used with a single argument, *N*, a number from 0 to 63 that identifies the character set. The `scsd` string is also used with the argument *N* and another, *M*, that gives the number of characters in the set. The `defc` string is used with three arguments: *A* gives the ASCII code representation for the character, *B* gives the width of the character in dots, and *D* is zero or one depending on whether the character is a “descender” or not. The `defc` string is also followed by a string of “image-data” bytes that describe how the character looks (see below).

Character set 0 is the default character set present after the printer has been initialized. Not every printer has 64 character sets, of course; using `scs` with an argument that doesn’t select an available character set should cause a null result from `tparm`.

If a character set has to be defined before it can be used, the `scsd` control sequence is to be used before defining the character set, and the `rcsd` is to be used after. They should also cause a null result from `tparm` when used with an argument *N* that doesn’t apply. If a character set still has to be selected after being defined, the `scs` control sequence should follow the `rcsd` control sequence. By examining the results of using each of the `scs`, `scsd`, and `rcsd` strings with a character set number in a call to `tparm`, a program can determine which of the three are needed.

Between use of the `scsd` and `rcsd` strings, the `defc` string should be used to define each character. To print any character on printers covered by `terminfo`, the ASCII code is sent to the printer. This is true for characters in an alternate set as well as “normal” characters. Thus the definition of a character includes the ASCII code that represents it. In addition, the width of the character in dots is given, along with an indication of whether the character should descend below the print line (such as the lower case letter “g” in most character sets). The width of the character in dots also indicates the number of image-data bytes that will follow the `defc` string. These image-data bytes indicate where in a dot-matrix pattern ink should be applied to “draw” the character; the number of these bytes and their form are defined below under “Dot-Mapped Graphics.”

It’s easiest for the creator of `terminfo` entries to refer to each character set by number; however, these numbers will be meaningless to the application developer. The `csnm` string alleviates this problem by providing names for each number.

terminfo(4)

When used with a character set number in a call to `tparm`, the `csnm` string will produce the equivalent name. These names should be used as a reference only. No naming convention is implied, although anyone who creates a `terminfo` entry for a printer should use names consistent with the names found in user documents for the printer. Application developers should allow a user to specify a character set by number (leaving it up to the user to examine the `csnm` string to determine the correct number), or by name, where the application examines the `csnm` string to determine the corresponding character set number.

These capabilities are likely to be used only with dot-matrix printers. If they are not available, the strings should not be defined. For printers that have manually changed print-wheels or font cartridges, the boolean `daisy` is set.

Section 2-6: Dot-Matrix Graphics

Dot-matrix printers typically have the capability of reproducing “raster-graphics” images. Three new numeric capabilities and three new string capabilities can help a program draw raster-graphics images independent of the type of dot-matrix printer or the number of pins or dots the printer can handle at one time.

Dot-Matrix Graphics

`npins` Number of pins, N , in print-head
`spinv` Spacing of pins vertically in pins per inch
`spinh` Spacing of dots horizontally in dots per inch
`porder` Matches software bits to print-head pins
`sbim` Start printing bit image graphics, B bits wide
`rbim` End printing bit image graphics

The `sbim` string is used with a single argument, B , the width of the image in dots.

The model of dot-matrix or raster-graphics that `terminfo` presents is similar to the technique used for most dot-matrix printers: each pass of the printer’s print-head is assumed to produce a dot-matrix that is N dots high and B dots wide. This is typically a wide, squat, rectangle of dots. The height of this rectangle in dots will vary from one printer to the next; this is given in the `npins` numeric capability. The size of the rectangle in fractions of an inch will also vary; it can be deduced from the `spinv` and `spinh` numeric capabilities. With these three values an application can divide a complete raster-graphics image into several horizontal strips, perhaps interpolating to account for different dot spacing vertically and horizontally.

The `sbim` and `rbim` strings are used to start and end a dot-matrix image, respectively. The `sbim` string is used with a single argument that gives the width of the dot-matrix in dots. A sequence of “image-data bytes” are sent to the printer after the `sbim` string and before the `rbim` string. The number of bytes is an integral multiple of the width of the dot-matrix; the multiple and the form of each byte is determined by the `porder` string as described below.

The `porder` string is a comma separated list of pin numbers optionally followed by an numerical offset. The offset, if given, is separated from the list with a semicolon.

The position of each pin number in the list corresponds to a bit in an 8-bit data byte. The pins are numbered consecutively from 1 to `npins`, with 1 being the top pin. Note that the term “pin” is used loosely here; “ink-jet” dot-matrix printers don’t have pins, but can be considered to have an equivalent method of applying a single dot of ink to paper. The bit positions in `porder` are in groups of 8, with the first position in each group the most significant bit and the last position the least significant bit. An application produces 8-bit bytes in the order of the groups in `porder`.

An application computes the “image-data bytes” from the internal image, mapping vertical dot positions in each print-head pass into 8-bit bytes, using a 1 bit where ink should be applied and 0 where no ink should be applied. This can be reversed (0 bit for ink, 1 bit for no ink) by giving a negative pin number. If a position is skipped in `porder`, a 0 bit is used. If a position has a lower case ‘x’ instead of a pin number, a 1 bit is used in the skipped position. For consistency, a lower case ‘o’ can be used to represent a 0 filled, skipped bit. There must be a multiple of 8 bit positions used or skipped in `porder`; if not, 0 bits are used to fill the last byte in the least significant bits. The offset, if given, is added to each data byte; the offset can be negative.

Some examples may help clarify the use of the `porder` string. The AT&T 470, AT&T 475 and C.Itoh 8510 printers provide eight pins for graphics. The pins are identified top to bottom by the 8 bits in a byte, from least significant to most. The `porder` strings for these printers would be `8,7,6,5,4,3,2,1`. The AT&T 478 and AT&T 479 printers also provide eight pins for graphics. However, the pins are identified in the reverse order. The `porder` strings for these printers would be `1,2,3,4,5,6,7,8`. The AT&T 5310, AT&T 5320, DEC LA100, and DEC LN03 printers provide six pins for graphics. The pins are identified top to bottom by the decimal values 1, 2, 4, 8, 16 and 32. These correspond to the low six bits in an 8-bit byte, although the decimal values are further offset by the value 63. The `porder` string for these printers would be `,,6,5,4,3,2,1;63`, or alternately `o,o,6,5,4,3,2,1;63`.

Section 2-7: Effect of Changing Printing Resolution

If the control sequences to change the character pitch or the line pitch are used, the pin or dot spacing may change:

Dot-Matrix Graphics
Changing the Character/Line Pitches

`cp` Change character pitch
`cpix` If set, `cp` changes `spinh`
`lp` Change line pitch
`lpix` If set, `lp` changes `spinv`

Programs that use `cp` or `lp` should recalculate the dot spacing:

Dot-Matrix Graphics
Effects of Changing the Character/Line Pitches

Before After

terminfo(4)

Using `cpi` with `cpix` clear:
`$bold spinh '$ $bold spinh$`

Using `cpi` with `cpix` set:
`$bold spinh '$ $bold spinh = bold spinh ' cdot bold orhi over
{ bold {orhi ' } }$`

Using `lpi` with `lpix` clear:
`$bold spinv '$ $bold spinv$`

Using `lpi` with `lpix` set:
`$bold spinv '$ $bold spinv = bold {spinv ' } cdot bold orhi over
{ bold {orhi ' } }$`

Using `chr`:
`$bold spinh '$ $bold spinh$`

Using `cvr`:
`$bold spinv '$ $bold spinv$`

`orhi'` and `orhi` are the values of the horizontal resolution in steps per inch, before using `cpi` and after using `cpi`, respectively. Likewise, `orvi'` and `orvi` are the values of the vertical resolution in steps per inch, before using `lpi` and after using `lpi`, respectively. Thus, the changes in the dots per inch for dot-matrix graphics follow the changes in steps per inch for printer resolution.

Section 2-8: Print Quality

Many dot-matrix printers can alter the dot spacing of printed text to produce near "letter quality" printing or "draft quality" printing. Usually it is important to be able to choose one or the other because the rate of printing generally falls off as the quality improves. There are three new strings used to describe these capabilities.

Print Quality

`snlq` Set near-letter quality print
`snrmq` Set normal quality print
`sdrfq` Set draft quality print

The capabilities are listed in decreasing levels of quality. If a printer doesn't have all three levels, one or two of the strings should be left blank as appropriate.

Section 2-9: Printing Rate and Buffer Size

Because there is no standard protocol that can be used to keep a program synchronized with a printer, and because modern printers can buffer data before printing it, a program generally cannot determine at any time what has been printed. Two new numeric capabilities can help a program estimate what has been printed.

Print Rate/Buffer Size

`cps` Nominal print rate in characters per second
`bufsz` Buffer capacity in characters

`cps` is the nominal or average rate at which the printer prints characters; if this value is not given, the rate should be estimated at one-tenth the prevailing baud rate. `bufsz` is the maximum number of subsequent characters buffered before the guaranteed printing of an earlier character, assuming proper flow control has been used. If this value is not given it is assumed that the printer does not buffer characters, but prints them as they are received.

As an example, if a printer has a 1000-character buffer, then sending the letter “a” followed by 1000 additional characters is guaranteed to cause the letter “a” to print. If the same printer prints at the rate of 100 characters per second, then it should take 10 seconds to print all the characters in the buffer, less if the buffer is not full. By keeping track of the characters sent to a printer, and knowing the print rate and buffer size, a program can synchronize itself with the printer.

Note that most printer manufacturers advertise the maximum print rate, not the nominal print rate. A good way to get a value to put in for `cps` is to generate a few pages of text, count the number of printable characters, and then see how long it takes to print the text.

Applications that use these values should recognize the variability in the print rate. Straight text, in short lines, with no embedded control sequences will probably print at close to the advertised print rate and probably faster than the rate in `cps`. Graphics data with a lot of control sequences, or very long lines of text, will print at well below the advertised rate and below the rate in `cps`. If the application is using `cps` to decide how long it should take a printer to print a block of text, the application should pad the estimate. If the application is using `cps` to decide how much text has already been printed, it should shrink the estimate. The application will thus err in favor of the user, who wants, above all, to see all the output in its correct place.

FILES	<code>/usr/share/lib/terminfo/?/*</code>	compiled terminal description database
	<code>/usr/share/lib/.COREterm/?/*</code>	subset of compiled terminal description database
	<code>/usr/share/lib/tabset/*</code>	tab settings for some terminals, in a format appropriate to be output to the terminal (escape sequences that set margins and tabs)

SEE ALSO `ls(1)`, `pg(1)`, `stty(1)`, `tput(1)`, `tty(1)`, `vi(1)`, `infocmp(1M)`, `tic(1M)`, `printf(3C)`, `curses(3CURSES)`, `curses(3XCURSES)`

NOTES The most effective way to prepare a terminal description is by imitating the description of a similar terminal in `terminfo` and to build up a description gradually, using partial descriptions with a screen oriented editor, such as `vi`, to check that they are correct. To easily test a new terminal description the environment variable `TERMINFO` can be set to the pathname of a directory containing the compiled

terminfo(4)

description, and programs will look there rather than in
`/usr/share/lib/terminfo`.

NAME | TIMEZONE – set default system time zone and locale

SYNOPSIS | `/etc/TIMEZONE /etc/default/init`

DESCRIPTION | This file sets the time zone environment variable TZ, and the locale-related environment variables LANG, LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, LC_NUMERIC, and LC_TIME.

| `/etc/TIMEZONE` is a symbolic link to `/etc/default/init`.

| The number of environments that can be set from `/etc/default/init` is limited to 20.

SEE ALSO | `init(1M)`, `ctime(3C)`, `environ(5)`

timezone(4)

NAME	timezone – default timezone data base
SYNOPSIS	/etc/timezone
DESCRIPTION	<p>The timezone file contains information regarding the default timezone for each host in a domain. Alternatively, a single default line for the entire domain may be specified. Each entry has the format:</p> <p><i>Timezone-name official-host-or-domain-name</i></p> <p>Items are separated by any number of blanks and/or TAB characters. A '#' indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file. The timezone is a pathname relative to the directory /usr/share/lib/zoneinfo.</p> <p>This file is not actually referenced by any system software; it is merely used as a source file to construct the NIS timezone.byname map. This map is read by sysidtool(1M) to initialize the timezone of the client system at installation time. For more information, see the Solaris 9 Installation Guide.</p> <p>The timezone file does not set the timezone environment variable TZ. See TIMEZONE(4) for information to set the TZ environment variable.</p>
EXAMPLES	<p>EXAMPLE 1 Typical timezone line</p> <p>Here is a typical line from the /etc/timezone file:</p> <pre>US/Eastern East.Sun.COM #Sun East Coast</pre>
FILES	/etc/timezone
SEE ALSO	sysidtool(1M), TIMEZONE(4) Solaris 9 Installation Guide

NAME	tnf_kernel_probes – TNF kernel probes																				
DESCRIPTION	<p>The set of probes (trace instrumentation points) available in the standard kernel. The probes log trace data to a kernel trace buffer in Trace Normal Form (TNF). Kernel probes are controlled by <code>prex(1)</code>. A snapshot of the kernel trace buffer can be made using <code>tnfextract(1)</code> and examined using <code>tnfdump(1)</code>.</p> <p>Each probe has a <i>name</i> and is associated with a set of symbolic <i>keys</i>, or <i>categories</i>. These are used to select and control probes from <code>prex(1)</code>. A probe that is enabled for tracing generates a TNF record, called an <i>event record</i>. An event record contains two common members and may contain other probe-specific data members.</p>																				
Common Members	<table border="0"> <tr> <td><code>tnf_probe_event</code></td> <td><code>tag</code></td> <td></td> </tr> <tr> <td><code>tnf_time_delta</code></td> <td><code>time_delta</code></td> <td></td> </tr> </table> <p><code>tag</code> Encodes TNF references to two other records:</p> <table border="0"> <tr> <td><code>tag</code></td> <td>Describes the layout of the event record.</td> </tr> <tr> <td><code>schedule</code></td> <td>Identifies the writing thread and also contains a 64-bit base time in nanoseconds.</td> </tr> </table> <p><code>time_delta</code> A 32-bit time offset from the base time; the sum of the two times is the actual time of the event.</p>	<code>tnf_probe_event</code>	<code>tag</code>		<code>tnf_time_delta</code>	<code>time_delta</code>		<code>tag</code>	Describes the layout of the event record.	<code>schedule</code>	Identifies the writing thread and also contains a 64-bit base time in nanoseconds.										
<code>tnf_probe_event</code>	<code>tag</code>																				
<code>tnf_time_delta</code>	<code>time_delta</code>																				
<code>tag</code>	Describes the layout of the event record.																				
<code>schedule</code>	Identifies the writing thread and also contains a 64-bit base time in nanoseconds.																				
Threads	<p><code>thread_create</code></p> <table border="0"> <tr> <td><code>tnf_kthread_id</code></td> <td><code>tid</code></td> </tr> <tr> <td><code>tnf_pid</code></td> <td><code>pid</code></td> </tr> <tr> <td><code>tnf_symbol</code></td> <td><code>start_pc</code></td> </tr> </table> <p>Thread creation event.</p> <table border="0"> <tr> <td><code>tid</code></td> <td>The thread identifier for the new thread.</td> </tr> <tr> <td><code>pid</code></td> <td>The process identifier for the new thread.</td> </tr> <tr> <td><code>start_pc</code></td> <td>The kernel address of its start routine.</td> </tr> </table> <p><code>thread_state</code></p> <table border="0"> <tr> <td><code>tnf_kthread_id</code></td> <td><code>tid</code></td> </tr> <tr> <td><code>tnf_microstate</code></td> <td><code>state</code></td> </tr> </table> <p>Thread microstate transition events.</p> <table border="0"> <tr> <td><code>tid</code></td> <td>Optional; if it is absent, the event is for the writing thread, otherwise the event is for the specified thread.</td> </tr> <tr> <td><code>state</code></td> <td>Indicates the thread state: <ul style="list-style-type: none"> ■ Running in user mode. ■ Running in system mode. ■ Asleep waiting for a user-mode lock. ■ Asleep on a kernel object. ■ Runnable (waiting for a cpu). </td> </tr> </table>	<code>tnf_kthread_id</code>	<code>tid</code>	<code>tnf_pid</code>	<code>pid</code>	<code>tnf_symbol</code>	<code>start_pc</code>	<code>tid</code>	The thread identifier for the new thread.	<code>pid</code>	The process identifier for the new thread.	<code>start_pc</code>	The kernel address of its start routine.	<code>tnf_kthread_id</code>	<code>tid</code>	<code>tnf_microstate</code>	<code>state</code>	<code>tid</code>	Optional; if it is absent, the event is for the writing thread, otherwise the event is for the specified thread.	<code>state</code>	Indicates the thread state: <ul style="list-style-type: none"> ■ Running in user mode. ■ Running in system mode. ■ Asleep waiting for a user-mode lock. ■ Asleep on a kernel object. ■ Runnable (waiting for a cpu).
<code>tnf_kthread_id</code>	<code>tid</code>																				
<code>tnf_pid</code>	<code>pid</code>																				
<code>tnf_symbol</code>	<code>start_pc</code>																				
<code>tid</code>	The thread identifier for the new thread.																				
<code>pid</code>	The process identifier for the new thread.																				
<code>start_pc</code>	The kernel address of its start routine.																				
<code>tnf_kthread_id</code>	<code>tid</code>																				
<code>tnf_microstate</code>	<code>state</code>																				
<code>tid</code>	Optional; if it is absent, the event is for the writing thread, otherwise the event is for the specified thread.																				
<code>state</code>	Indicates the thread state: <ul style="list-style-type: none"> ■ Running in user mode. ■ Running in system mode. ■ Asleep waiting for a user-mode lock. ■ Asleep on a kernel object. ■ Runnable (waiting for a cpu). 																				

tnf_kernel_probes(4)

- Stopped.

The values of this member are defined in `<sys/msacct.h>`. Note that to reduce trace output, transitions between the *system* and *user* microstates that are induced by system calls are not traced. This information is implicit in the system call entry and exit events.

thread_exit

Thread termination event for writing thread. This probe has no data members other than the common members.

Scheduling

thread_queue

```
tnf_kthread_id  tid
tnf_cpuid       cpuid
tnf_long        priority
tnf_ulong       queue_length
```

Thread scheduling events. These are triggered when a runnable thread is placed on a dispatch queue.

cpuid Specifies the cpu to which the queue is attached.

priority The (global) dispatch priority of the thread.

queue_length The current length of the cpu's dispatch queue.

Blocking

thread_block

```
tnf_opaque      reason
tnf_symbols      stack
```

Thread blockage event. This probe captures a partial stack backtrace when the current thread blocks.

reason The address of the object on which the thread is blocking.

symbols References a TNF array of kernel addresses representing the PCs on the stack at the time the thread blocks.

System Calls

syscall_start

```
tnf_sysnum      sysnum
```

System call entry event.

sysnum The system call number. The writing thread implicitly enters the *system* microstate with this event.

syscall_end

```
tnf_long        rval1
tnf_long        rval2
tnf_long        errno
```

System call exit event.

rval1 and *rval2* The two return values of the system call

errno The error return.

The writing thread implicitly enters the *user* microstate with this event.

Page Faults

`address_fault`

tnf_opaque *address*
tnf_fault_type *fault_type*
tnf_seg_access *access*

Address-space fault event.

address Gives the faulting virtual address.

fault_type Gives the fault type: invalid page, protection fault, software requested locking or unlocking.

access Gives the desired access protection: read, write, execute or create. The values for these two members are defined in `<vm/seg_enum.h>`.

`major_fault`

tnf_opaque *vnode*
tnf_offset *offset*

Major page fault event. The faulting page is mapped to the file given by the *vnode* member, at the given *offset* into the file. (The faulting virtual address is in the most recent `address_fault` event for the writing thread.)

`anon_private`

tnf_opaque *address*

Copy-on-write page fault event.

address The virtual address at which the new page is mapped.

`anon_zero`

tnf_opaque *address*

Zero-fill page fault event.

address The virtual address at which the new page is mapped.

`page_unmap`

tnf_opaque *vnode*
tnf_offset *offset*

Page unmapping event. This probe marks the unmapping of a file system page from the system.

tnf_kernel_probes(4)

	<i>vnode</i> and <i>offset</i>	Identifies the file and offset of the page being unmapped.
Pageins and Pageouts	pagein	
	tnf_opaque	<i>vnode</i>
	tnf_offset	<i>offset</i>
	tnf_size	<i>size</i>
	Pagein start event. This event signals the initiation of pagein I/O.	
	<i>vnodeandoffset</i>	Identifies the file and offset to be paged in.
	<i>size</i>	Specifies the number of bytes to be paged in.
	pageout	
	tnf_opaque	<i>vnode</i>
	tnf_ulong	<i>pages_pageout</i>
	tnf_ulong	<i>pages_freed</i>
	tnf_ulong	<i>pages_reclaimed</i>
	Pageout completion event. This event signals the completion of pageout I/O.	
	<i>vnode</i>	Identifies the file of the pageout request.
	<i>pages_pageout</i>	The number of pages written out.
	<i>pages_freed</i>	The number of pages freed after being written out.
	<i>pages_reclaimed</i>	The number of pages reclaimed after being written out.
Page Daemon (Page Stealer)	pageout_scan_start	
	tnf_ulong	<i>pages_free</i>
	tnf_ulong	<i>pages_needed</i>
	Page daemon scan start event. This event signals the beginning of one iteration of the page daemon.	
	<i>pages_free</i>	The number of free pages in the system.
	<i>pages_needed</i>	The number of pages desired free.
	pageout_scan_end	
	tnf_ulong	<i>pages_free</i>
	tnf_ulong	<i>pages_scanned</i>
	Page daemon scan end event. This event signals the end of one iteration of the page daemon.	
	<i>pages_free</i>	The number of free pages in the system.
	<i>pages_scanned</i>	The number of pages examined by the page daemon. (Potentially more pages will be freed when any queued pageout requests complete.)

Swapper	<code>swapout_process</code>	
	<code>tnf_pid</code>	<i>pid</i>
	<code>tnf_ulong</code>	<i>page_count</i>
	Address space swapout event. This event marks the swapping out of a process address space.	
	<i>pid</i>	Identifies the process.
	<i>page_count</i>	Reports the number of pages either freed or queued for pageout.
	<code>swapout_lwp</code>	
	<code>tnf_pid</code>	<i>pid</i>
	<code>tnf_lwpid</code>	<i>lwpid</i>
	<code>tnf_kthread_id</code>	<i>tid</i>
	<code>tnf_ulong</code>	<i>page_count</i>
	Light-weight process swapout event. This event marks the swapping out of an LWP and its stack.	
<i>pid</i>	The LWP's process identifier	
<i>lwpid</i>	The LWP identifier	
<i>tid member</i>	The LWP's kernel thread identifier.	
<i>page_count</i>	The number of pages swapped out.	
<code>swpin_lwp</code>		
<code>tnf_pid</code>	<i>pid</i>	
<code>tnf_lwpid</code>	<i>lwpid</i>	
<code>tnf_kthread_id</code>	<i>tid</i>	
<code>tnf_ulong</code>	<i>page_count</i>	
Light-weight process swpin event. This event marks the swapping in of an LWP and its stack.		
<i>pid</i>	The LWP's process identifier.	
<i>lwpid</i>	The LWP identifier.	
<i>tid</i>	The LWP's kernel thread identifier.	
<i>page_count</i>	The number of pages swapped in.	
Local I/O	<code>strategy</code>	
	<code>tnf_device</code>	<i>device</i>
	<code>tnf_diskaddr</code>	<i>block</i>
	<code>tnf_size</code>	<i>size</i>
	<code>tnf_opaque</code>	<i>buf</i>
	<code>tnf_bioflags</code>	<i>flags</i>
	Block I/O strategy event. This event marks a call to the <code>strategy(9E)</code> function of a block device driver.	

tnf_kernel_probes(4)

<i>device</i>	Contains the major and minor numbers of the device.
<i>block</i>	The logical block number to be accessed on the device.
<i>size</i>	The size of the I/O request.
<i>buf</i>	The kernel address of the buf(9S) structure associated with the transfer.
<i>flags</i>	The buf(9S) flags associated with the transfer.
biodone	
tnf_device	<i>device</i>
tnf_diskaddr	<i>block</i>
tnf_opaque	<i>buf</i>
Buffered I/O completion event. This event marks calls to the biodone(9F) function.	
<i>device</i>	Contains the major and minor numbers of the device.
<i>block</i>	The logical block number accessed on the device.
<i>buf</i>	The kernel address of the buf(9S) structure associated with the transfer.
physio_start	
tnf_device	<i>device</i>
tnf_offset	<i>offset</i>
tnf_size	<i>size</i>
tnf_bioflags	<i>rw</i>
Raw I/O start event. This event marks entry into the physio(9F) fufnction which performs unbuffered I/O.	
<i>device</i>	Contains the major and minor numbers of the device of the transfer.
<i>offset</i>	The logical offset on the device for the transfer.
<i>size</i>	The number of bytes to be transferred.
<i>rw</i>	The direction of the transfer: read or write (see buf(9S)).
physio_end	
tnf_device	<i>device</i>
Raw I/O end event. This event marks exit from the physio(9F) fufnction.	
<i>device</i>	The major and minor numbers of the device of the transfer.

USAGE Use the `prex` utility to control kernel probes. The standard `prex` commands to list and manipulate probes are available to you, along with commands to set up and manage kernel tracing.

Kernel probes write trace records into a kernel trace buffer. You must copy the buffer into a TNF file for post-processing; use the `tnfextract` utility for this.

You use the `tnfdump` utility to examine a kernel trace file. This is exactly the same as examining a user-level trace file.

The steps you typically follow to take a kernel trace are:

1. Become superuser (`su`).
2. Allocate a kernel trace buffer of the desired size (`prex`).
3. Select the probes you want to trace and enable (`prex`).
4. Turn kernel tracing on (`prex`).
5. Run your application.
6. Turn kernel tracing off (`prex`).
7. Extract the kernel trace buffer (`tnfextract`).
8. Disable all probes (`prex`).
9. Deallocate the kernel trace buffer (`prex`).
10. Examine the trace file (`tnfdump`).

A convenient way to follow these steps is to use two shell windows; run an interactive `prex` session in one, and run your application and `tnfextract` in the other.

ts_dptbl(4)

NAME	ts_dptbl – time-sharing dispatcher parameter table								
DESCRIPTION	<p>The process scheduler (or dispatcher) is the portion of the kernel that controls allocation of the CPU to processes. The scheduler supports the notion of scheduling classes where each class defines a scheduling policy, used to schedule processes within that class. Associated with each scheduling class is a set of priority queues on which ready to run processes are linked. These priority queues are mapped by the system configuration into a set of global scheduling priorities which are available to processes within the class. (The dispatcher always selects for execution the process with the highest global scheduling priority in the system.) The priority queues associated with a given class are viewed by that class as a contiguous set of priority levels numbered from 0 (lowest priority) to <i>n</i> (highest priority—a configuration-dependent value). The set of global scheduling priorities that the queues for a given class are mapped into might not start at zero and might not be contiguous (depending on the configuration).</p> <p>Processes in the time-sharing class which are running in user mode (or in kernel mode before going to sleep) are scheduled according to the parameters in a time-sharing dispatcher parameter table (<code>ts_dptbl</code>). Processes in the inter-active scheduling class are also scheduled according to the parameters in the time-sharing dispatcher parameter table. (Time-sharing processes and inter-active processes running in kernel mode after sleeping are run within a special range of priorities reserved for such processes and are not affected by the parameters in the <code>ts_dptbl</code> until they return to user mode.) The <code>ts_dptbl</code> consists of an array (<code>config_ts_dptbl []</code>) of parameter structures (<code>struct tsdpent_t</code>), one for each of the <i>n</i> priority levels used by time-sharing processes and inter-active processes in user mode. The structures are accessed via a pointer, (<code>ts_dptbl</code>), to the array. The properties of a given priority level <i>i</i> are specified by the <i>i</i>th parameter structure in this array (<code>ts_dptbl [i]</code>).</p> <p>A parameter structure consists of the following members. These are also described in the <code>/usr/include/sys/ts.h</code> header.</p> <table><tr><td><code>ts_globpri</code></td><td>The global scheduling priority associated with this priority level. The mapping between time-sharing priority levels and global scheduling priorities is determined at boot time by the system configuration. <code>ts_globpri</code> is the only member of the <code>ts_dptbl</code> which cannot be changed with <code>dispadm(1M)</code>.</td></tr><tr><td><code>ts_quantum</code></td><td>The length of the time quantum allocated to processes at this level in ticks (Hz).</td></tr><tr><td><code>ts_tqexp</code></td><td>Priority level of the new queue on which to place a process running at the current level if it exceeds its time quantum. Normally this field links to a lower priority time-sharing level that has a larger quantum.</td></tr><tr><td><code>ts_slpret</code></td><td>Priority level of the new queue on which to place a process, that was previously in user mode at this level, when it returns to user mode after sleeping. Normally</td></tr></table>	<code>ts_globpri</code>	The global scheduling priority associated with this priority level. The mapping between time-sharing priority levels and global scheduling priorities is determined at boot time by the system configuration. <code>ts_globpri</code> is the only member of the <code>ts_dptbl</code> which cannot be changed with <code>dispadm(1M)</code> .	<code>ts_quantum</code>	The length of the time quantum allocated to processes at this level in ticks (Hz).	<code>ts_tqexp</code>	Priority level of the new queue on which to place a process running at the current level if it exceeds its time quantum. Normally this field links to a lower priority time-sharing level that has a larger quantum.	<code>ts_slpret</code>	Priority level of the new queue on which to place a process, that was previously in user mode at this level, when it returns to user mode after sleeping. Normally
<code>ts_globpri</code>	The global scheduling priority associated with this priority level. The mapping between time-sharing priority levels and global scheduling priorities is determined at boot time by the system configuration. <code>ts_globpri</code> is the only member of the <code>ts_dptbl</code> which cannot be changed with <code>dispadm(1M)</code> .								
<code>ts_quantum</code>	The length of the time quantum allocated to processes at this level in ticks (Hz).								
<code>ts_tqexp</code>	Priority level of the new queue on which to place a process running at the current level if it exceeds its time quantum. Normally this field links to a lower priority time-sharing level that has a larger quantum.								
<code>ts_slpret</code>	Priority level of the new queue on which to place a process, that was previously in user mode at this level, when it returns to user mode after sleeping. Normally								

	this field links to a higher priority level that has a smaller quantum.
<code>ts_maxwait</code>	A per process counter, <code>ts_dispwait</code> is initialized to zero each time a time-sharing or inter-active process is placed back on the dispatcher queue after its time quantum has expired or when it is awakened (<code>ts_dispwait</code> is not reset to zero when a process is preempted by a higher priority process). This counter is incremented once per second for each process on a dispatcher or sleep queue. If a process' <code>ts_dispwait</code> value exceeds the <code>ts_maxwait</code> value for its level, the process' priority is changed to that indicated by <code>ts_lwait</code> . The purpose of this field is to prevent starvation.
<code>ts_lwait</code>	Move a process to this new priority level if <code>ts_dispwait</code> is greater than <code>ts_maxwait</code> .

An administrator can affect the behavior of the time-sharing portion of the scheduler by reconfiguring the `ts_dptbl`. Since processes in the time-sharing and inter-active scheduling classes share the same dispatch parameter table (`ts_dptbl`), changes to this table will affect both scheduling classes. There are two methods available for doing this: reconfigure with a loadable module at boot-time or by using `dispadmin(1M)` at run-time.

ts_dptbl Loadable Module

The `ts_dptbl` can be reconfigured with a loadable module which contains a new time sharing dispatch table. The module containing the dispatch table is separate from the TS loadable module which contains the rest of the time-sharing and inter-active software. This is the only method that can be used to change the number of time-sharing priority levels or the set of global scheduling priorities used by the time-sharing and inter-active classes. The relevant procedure and source code is described in the `REPLACING THE TS_DPTBL LOADABLE MODULE` section.

dispadmin Configuration File

With the exception of `ts_globpri` all of the members of the `ts_dptbl` can be examined and modified on a running system using the `dispadmin(1M)` command. Invoking `dispadmin` for the time-sharing or inter-active class allows the administrator to retrieve the current `ts_dptbl` configuration from the kernel's in-core table, or overwrite the in-core table with values from a configuration file. The configuration file used for input to `dispadmin` must conform to the specific format described below.

Blank lines are ignored and any part of a line to the right of a `#` symbol is treated as a comment. The first non-blank, non-comment line must indicate the resolution to be used for interpreting the `ts_quantum` time quantum values. The resolution is specified as

```
RES=res
```

ts_dptbl(4)

where *res* is a positive integer between 1 and 1,000,000,000 inclusive and the resolution used is the reciprocal of *res* in seconds (for example, RES=1000 specifies millisecond resolution). Although very fine (nanosecond) resolution may be specified, the time quantum lengths are rounded up to the next integral multiple of the system clock's resolution.

The remaining lines in the file are used to specify the parameter values for each of the time-sharing priority levels. The first line specifies the parameters for time-sharing level 0, the second line specifies the parameters for time-sharing level 1, etc. There must be exactly one line for each configured time-sharing priority level.

EXAMPLES

EXAMPLE 1 A Sample From a Configuration File

The following excerpt from a `dispadmin` configuration file illustrates the format. Note that for each line specifying a set of parameters there is a comment indicating the corresponding priority level. These level numbers indicate priority within the time-sharing and interactive classes, and the mapping between these time-sharing priorities and the corresponding global scheduling priorities is determined by the configuration specified in the `ts` master file. The level numbers are strictly for the convenience of the administrator reading the file and, as with any comment, they are ignored by `dispadmin`. `dispadmin` assumes that the lines in the file are ordered by consecutive, increasing priority level (from 0 to the maximum configured time-sharing priority). The level numbers in the comments should normally agree with this ordering; if for some reason they don't, however, `dispadmin` is unaffected.

```

EXAMPLE 2 Replacing The `ts_dptbl` Loadable Module

In order to change the size of the time sharing dispatch table, the loadable module which contains the dispatch table information will have to be built. It is recommended that you save the existing module before using the following procedure.

EXAMPLE 2 Replacing The ts_dptbl Loadable Module (Continued)

1. Place the dispatch table code shown below in a file called `ts_dptbl.c`. An example of this file follows.
2. Compile the code using the given compilation and link lines supplied.

```
cc -c -o -D_KERNEL
ts_dptbl.c
ld -r -o TS_DPTBL ts_dptbl.o
```

3. Copy the current dispatch table in `/kernel/sched` to `TS_DPTBL.bak`.
4. Replace the current `TS_DPTBL` in `/kernel/sched`.
5. You will have to make changes in the `/etc/system` file to reflect the changes to the sizes of the tables. See `system(4)`. The two variables affected are `ts_maxupri` and `ts_maxkmdpri`. The syntax for setting these is as follows:

```
set TS:ts_maxupri=(value for max time-sharing user priority)
set TS:ts_maxkmdpri=(number of kernel mode priorities - 1)
```

6. Reboot the system to use the new dispatch table.

Great care should be used in replacing the dispatch table using this method. If you do not get it right, panics may result, thus making the system unusable.

The following is an example of a `ts_dptbl.c` file used for building the new `ts_dptbl`.

```
/* BEGIN ts_dptbl.c */
#include <sys/proc.h>
#include <sys/priocntl.h>
#include <sys/class.h>
#include <sys/disp.h>
#include <sys/ts.h>
#include <sys/rtpriocntl.h>
/*
 * This is the loadable module wrapper.
 */
#include <sys/modctl.h>
extern struct mod_ops mod_miscops;
/*
 * Module linkage information for the kernel.
 */
static struct modlmisc modlmisc = {
    &mod_miscops, "Time sharing dispatch table"
};
static struct modlinkage modlinkage = {
    MODREV_1, &modlmisc, 0
};
_init()
{
    return (mod_install(&modlinkage));
}
_info(modinfop)
    struct modinfo *modinfop;
```

ts_dptbl(4)

EXAMPLE 2 Replacing The ts_dptbl Loadable Module (Continued)

```
{
    return (mod_info(&modlinkage, modinfop));
}
/*
 * array of global priorities used by ts procs sleeping or
 * running in kernel mode after sleep. Must have at least
 * 40 values.
 */
pri_t config_ts_kmdpris[] = {
    60,61,62,63,64,65,66,67,68,69,

System Administration Guide: Basic Administration

Programming Interfaces Guide

NOTES dispadmin does some limited sanity checking on the values supplied in the configuration file. The sanity checking is intended to ensure that the new ts_dptbl values do not cause the system to panic. The sanity checking does not attempt to analyze the effect that the new values will have on the performance of the system. Unusual ts_dptbl configurations may have a dramatic negative impact on the performance of the system.

No sanity checking is done on the ts_dptbl values specified in the TS_DPTBL loadable module. Specifying an inconsistent or nonsensical ts_dptbl configuration through the TS_DPTBL loadable module could cause serious performance problems and/or cause the system to panic.

NAME	ttydefs – file contains terminal line settings information for ttymon
DESCRIPTION	<p><code>/etc/ttydefs</code> is an administrative file that contains records divided into fields by colons (":"). This information used by <code>ttymon</code> to set up the speed and terminal settings for a TTY port.</p> <p>The <code>ttydefs</code> file contains the following fields:</p> <p><i>ttylabel</i> The string <code>ttymon</code> tries to match against the TTY port's <i>ttylabel</i> field in the port monitor administrative file. It often describes the speed at which the terminal is supposed to run, for example, 1200.</p> <p><i>initial-flags</i> Contains the initial <code>termio(7I)</code> settings to which the terminal is to be set. For example, the system administrator will be able to specify what the default erase and kill characters will be. <i>initial-flags</i> must be specified in the syntax recognized by the <code>stty</code> command.</p> <p><i>final-flags</i> <i>final-flags</i> must be specified in the same format as <i>initial-flags</i>. <code>ttymon</code> sets these final settings after a connection request has been made and immediately prior to invoking a port's service.</p> <p><i>autobaud</i> If the autobaud field contains the character 'A,' autobaud will be enabled. Otherwise, autobaud will be disabled. <code>ttymon</code> determines what line speed to set the TTY port to by analyzing the carriage returns entered. If autobaud has been disabled, the hunt sequence is used for baud rate determination.</p> <p><i>nextlabel</i> If the user indicates that the current terminal setting is not appropriate by sending a BREAK, <code>ttymon</code> searches for a <code>ttydefs</code> entry whose <i>ttylabel</i> field matches the <i>nextlabel</i> field. If a match is found, <code>ttymon</code> uses that field as its <i>ttylabel</i> field. A series of speeds is often linked together in this way into a closed set called a hunt sequence. For example, 4800 may be linked to 1200, which in turn is linked to 2400, which is finally linked to 4800.</p>

ttysrch(4)

NAME	ttysrch – directory search list for ttyname
DESCRIPTION	<p>ttysrch is an optional file that is used by the ttyname library routine. This file contains the names of directories in /dev that contain terminal and terminal-related device files. The purpose of this file is to improve the performance of ttyname by indicating which subdirectories in /dev contain terminal-related device files and should be searched first. These subdirectory names must appear on separate lines and must begin with /dev. Those path names that do not begin with /dev will be ignored and a warning will be sent to the console. Blank lines (lines containing only white space) and lines beginning with the comment character "#" will be ignored. For each file listed (except for the special entry /dev), ttyname will recursively search through subdirectories looking for a match. If /dev appears in the ttysrch file, the /dev directory itself will be searched but there will not be a recursive search through its subdirectories.</p> <p>When ttyname searches through the device files, it tries to find a file whose major/minor device number, file system identifier, and inode number match that of the file descriptor it was given as an argument. If a match is not found, it will settle for a match of just major/minor device and file system identifier, if one can be found. However, if the file descriptor is associated with a cloned device, this algorithm does not work efficiently because the inode number of the device file associated with a clonable device will never match the inode number of the file descriptor that was returned by the open of that clonable device. To help with these situations, entries can be put into the /etc/ttysrch file to improve performance when cloned devices are used as terminals on a system (for example, for remote login). However, this is only useful if the minor devices related to a cloned device are put into a subdirectory. (It is important to note that device files need not exist for cloned devices and if that is the case, ttyname will eventually fail.) An optional second field is used in the /etc/ttysrch file to indicate the matching criteria. This field is separated by white space (any combination of blanks or tabs). The letter M means major/minor device number, F means file system identifier, and I means inode number. If this field is not specified for an entry, the default is MFI which means try to match on all three. For cloned devices the field should be MF, which indicates that it is not necessary to match on the inode number.</p> <p>Without the /etc/ttysrch file, ttyname will search the /dev directory by first looking in the directories /dev/term, /dev/pts, and /dev/xt. If a system has terminal devices installed in directories other than these, it may help performance if the ttysrch file is created and contains that list of directories.</p>
EXAMPLES	<p>EXAMPLE 1 A sample display of /etc/ttysrch command.</p> <p>A sample /etc/ttysrch file follows:</p> <pre>/dev/term MFI /dev/pts MFI /dev/xt MFI /dev/slan MF</pre>

EXAMPLE 1 A sample display of `/etc/ttysrch` command. *(Continued)*

This file tells `ttyname` that it should first search through those directories listed and that when searching through the `/dev/slan` directory, if a file is encountered whose major/minor devices and file system identifier match that of the file descriptor argument to `ttyname`, this device name should be considered a match.

FILES `/etc/ttysrch`

ufsdump(4)

NAME ufsdump, dumpdates – incremental dump format

SYNOPSIS #include <sys/types.h>
#include <sys/inode.h>
#include <protocols/dumprestore.h>
/etc/dumpdates

DESCRIPTION Tapes used by ufsdump(1M) and ufsrestore(1M) contain:

- a header record
- two groups of bit map records
- a group of records describing directories
- a group of records describing files

The format of the header record and of the first record of each description as given in the include file <protocols/dumprestore.h> is:

```
#define TP_BSIZE                1024

#define NTREC                    10

#define HIGHDENSITYTREC        32

#define CARTRIDGETREC          63

#define TP_NINDIR                (TP_BSIZE/2)

#define TP_NINOS                 (TP_NINDIR / sizeof (long))

#define LBLSIZE                  16

#define NAMELEN                  64
```

```
#define NFS_MAGIC                (int) 60012

#define CHECKSUM                 (int) 84446
```

```
union u_data {
    char  s_addr[TP_NINDIR];
    long  s_inos[TP_NINOS];
union u_spl {
    char  dummy[TP_BSIZE];
    struct s_spl {
        long      c_type;
        time_t    c_date;
        time_t    c_ddate;
        long      c_volume;
        daddr_t   c_tapea;

ufsdump(4)

#define TS_TAPE	1
#define TS_INODE	2
#define TS_ADDR	4
#define TS_BITS	3
#define TS_CLRI	6
#define TS_END	5
#define TS_EOM	7

#define DR_NEWHEADER	1
#define DR_INODEINFO	2
#define DR_REDUMP	4
#define DR_TRUELIC	8
#define DUMPOUTFMT	"%-24s %c %s"
#define DUMPINFMT	"%24s %c %[^ \n] \n"

The constants are described as follows:

TP_BSIZE	Size of file blocks on the dump tapes. Note that TP_BSIZE must be a multiple of DEV_BSIZE.
NTREC	Default number of TP_BSIZE byte records in a physical tape block, changeable by the b option to ufsdump(1M).
HIGHDENSITYNTREC	Default number of TP_BSIZE byte records in a physical tape block on 6250 BPI or higher density tapes.
CARTRIDGETREC	Default number of TP_BSIZE records in a physical tape block on cartridge tapes.
TP_NINDIR	Number of indirect pointers in a TS_INODE or TS_ADDR record. It must be a power of 2.
TP_NINOS	The maximum number of volumes on a tape. Used for tape labeling in hsmdump and hsmrestore (available with Online:Backup 2.0 optional software package SUNWhsm).
LBLSIZE	The maximum size of a volume label. Used for tape labeling in hsmdump and hsmrestore (available with Online:Backup 2.0 optional software package SUNWhsm).

NAMELEN	The maximum size of a host's name.
NFS_MAGIC	All header records have this number in <code>c_magic</code> .
CHECKSUM	Header records checksum to this value.

The `TS_` entries are used in the `c_type` field to indicate what sort of header this is. The types and their meanings are as follows:

TS_TAPE	Tape volume label.
TS_INODE	A file or directory follows. The <code>c_dinode</code> field is a copy of the disk inode and contains bits telling what sort of file this is.
TS_ADDR	A subrecord of a file description. See <code>s_addr</code> s below.
TS_BITS	A bit map follows. This bit map has a one bit for each inode that was dumped.
TS_CLRI	A bit map follows. This bit map contains a zero bit for all inodes that were empty on the file system when dumped.
TS_END	End of tape record.
TS_EOM	floppy EOM — restore compat with old dump

The flags are described as follows:

DR_NEWHEADER	New format tape header.
DR_INFODEINFO	Header contains starting inode info.
DR_REDUMP	Dump contains recopies of active files.
DR_TRUEINC	Dump is a "true incremental".
DUMPOUTFMT	Name, <code>incon</code> , and <code>ctime</code> (date) for <code>printf</code> .
DUMPINFMT	Inverse for <code>scanf</code> .

The fields of the header structure are as follows:

<code>s_addr</code>	An array of bytes describing the blocks of the dumped file. A byte is zero if the block associated with that byte was not present on the file system; otherwise, the byte is non-zero. If the block was not present on the file system, no block was dumped; the block will be stored as a hole in the file. If there is not sufficient space in this record to describe all the blocks in a file, <code>TS_ADDR</code> records will be scattered through the file, each one picking up where the last left off
<code>s_inos</code>	The starting inodes on tape.
<code>c_type</code>	The type of the record.
<code>c_date</code>	The date of the previous dump.

ufsdump(4)

<code>c_ddate</code>	The date of this dump.
<code>c_volume</code>	The current volume number of the dump.
<code>c_tapea</code>	The logical block of this record.
<code>c_inumber</code>	The number of the inode being dumped if this is of type <code>TS_INODE</code> .
<code>c_magic</code>	This contains the value <code>MAGIC</code> above, truncated as needed.
<code>c_checksum</code>	This contains whatever value is needed to make the record sum to <code>CHECKSUM</code> .
<code>c_dinode</code>	This is a copy of the inode as it appears on the file system.
<code>c_count</code>	The count of bytes in <code>s_addrs</code> .
<code>u_data c_data</code>	The union of either <code>u_data c_data</code> or <code>s_inos</code> .
<code>c_label</code>	Label for this dump.
<code>c_level</code>	Level of this dump.
<code>c_filesys</code>	Name of dumped file system.
<code>c_dev</code>	Name of dumped service.
<code>c_host</code>	Name of dumped host.
<code>c_flags</code>	Additional information.
<code>c_firstrec</code>	First record on volume.
<code>c_spare</code>	Reserved for future uses.

Each volume except the last ends with a tapemark (read as an end of file). The last volume ends with a `TS_END` record and then the tapemark.

The dump history is kept in the file `/etc/dumpdates`. It is an ASCII file with three fields separated by white space:

- The name of the device on which the dumped file system resides.
- The level number of the dump tape; see `ufsdump(1M)`.
- The date of the incremental dump in the format generated by `ctime(3C)`.

`DUMPOUTFMT` is the format to use when using `printf(3C)` to write an entry to `/etc/dumpdates`; `DUMPINFMT` is the format to use when using `scanf(3C)` to read an entry from `/etc/dumpdates`.

ATTRIBUTES

updaters(4)

NAME	updaters – configuration file for NIS updating
SYNOPSIS	<code>/var/yp/updaters</code>
DESCRIPTION	<p>The file <code>/var/yp/updaters</code> is a makefile (see <code>make(1S)</code>) which is used for updating the Network Information Service (NIS) databases. Databases can only be updated in a secure network, that is, one that has a <code>publickey(4)</code> database. Each entry in the file is a make target for a particular NIS database. For example, if there is an NIS database named <code>passwd.byname</code> that can be updated, there should be a make target named <code>passwd.byname</code> in the <code>updaters</code> file with the command to update the file.</p> <p>The information necessary to make the update is passed to the update command through standard input. The information passed is described below (all items are followed by a NEWLINE except for 4 and 6):</p> <ol style="list-style-type: none">1. Network name of client wishing to make the update (a string).2. Kind of update (an integer).3. Number of bytes in key (an integer).4. Actual bytes of key.5. Number of bytes in data (an integer).6. Actual bytes of data. <p>After receiving this information through standard input, the command to update the particular database determines whether the user is allowed to make the change. If not, it exits with the status <code>YPERR_ACCESS</code>. If the user is allowed to make the change, the command makes the change and exits with a status of zero. If there are any errors that may prevent the <code>updaters</code> from making the change, it should exit with the status that matches a valid NIS error code described in <code><rpcsvc/ypclnt.h></code>.</p>
FILES	<code>/var/yp/updaters</code> The makefile used for updating the NIS databases.
SEE ALSO	<code>make(1S)</code> , <code>rpc.yppupdated(1M)</code> , <code>publickey(4)</code>
NOTES	The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

NAME	user_attr – extended user attributes database																
SYNOPSIS	/etc/user_attr																
DESCRIPTION	<p>/etc/user_attr is a local source of extended attributes associated with users and roles. user_attr can be used with other user attribute sources, including the user_attr NIS map and NIS+ table. Programs use the getuserattr(3SECDB) routines to gain access to this information.</p> <p>The search order for multiple user_attr sources is specified in the /etc/nsswitch.conf file, as described in the nsswitch.conf(4) man page. The search order follows that for passwd(4).</p> <p>Each entry in the user_attr databases consists of a single line with five fields separated by colons (:). Line continuations using the backslash (\) character are permitted. Each entry has the form:</p> <pre>user:qualifier:res1:res2:attr</pre> <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;"><i>user</i></td> <td>The name of the user as specified in the passwd(4) database.</td> </tr> <tr> <td style="vertical-align: top;"><i>qualifier</i></td> <td>Reserved for future use.</td> </tr> <tr> <td style="vertical-align: top;"><i>res1</i></td> <td>Reserved for future use.</td> </tr> <tr> <td style="vertical-align: top;"><i>res2</i></td> <td>Reserved for future use.</td> </tr> <tr> <td style="vertical-align: top;"><i>attr</i></td> <td> <p>An optional list of semicolon-separated (;) key-value pairs that describe the security attributes to apply to the object upon execution. Zero or more keys may be specified. There are five valid keys: <i>auths</i>, <i>profiles</i>, <i>roles</i>, <i>type</i>, and <i>project</i>.</p> <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;"><i>auths</i></td> <td>Specifies a comma-separated list of authorization names chosen from those names defined in the auth_attr(4) database. Authorization names may be specified using the asterisk (*) character as a wildcard. For example, solaris.printer.* means all of Sun's printer authorizations.</td> </tr> <tr> <td style="vertical-align: top;"><i>profiles</i></td> <td>Contains an ordered, comma-separated list of profile names chosen from prof_attr(4). Profiles are enforced by the profile shells, pfcsh, pfksh, and pfsh. See pfsh(1). If no profiles are assigned, the profile shells do not allow the user to execute any commands.</td> </tr> <tr> <td style="vertical-align: top;"><i>roles</i></td> <td>Can be assigned a comma-separated list of role names from the set of user accounts in this database whose type field indicates the</td> </tr> </table> </td> </tr> </table>	<i>user</i>	The name of the user as specified in the passwd(4) database.	<i>qualifier</i>	Reserved for future use.	<i>res1</i>	Reserved for future use.	<i>res2</i>	Reserved for future use.	<i>attr</i>	<p>An optional list of semicolon-separated (;) key-value pairs that describe the security attributes to apply to the object upon execution. Zero or more keys may be specified. There are five valid keys: <i>auths</i>, <i>profiles</i>, <i>roles</i>, <i>type</i>, and <i>project</i>.</p> <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;"><i>auths</i></td> <td>Specifies a comma-separated list of authorization names chosen from those names defined in the auth_attr(4) database. Authorization names may be specified using the asterisk (*) character as a wildcard. For example, solaris.printer.* means all of Sun's printer authorizations.</td> </tr> <tr> <td style="vertical-align: top;"><i>profiles</i></td> <td>Contains an ordered, comma-separated list of profile names chosen from prof_attr(4). <i>profiles</i>	Contains an ordered, comma-separated list of profile names chosen from prof_attr(4). Profiles are enforced by the profile shells, pfcsh, pfksh, and pfsh. See pfsh(1). If no profiles are assigned, the profile shells do not allow the user to execute any commands.																
<i>roles</i>	Can be assigned a comma-separated list of role names from the set of user accounts in this database whose type field indicates the																

user_attr(4)

	account is a role. If the <code>roles</code> key value is not specified, the user is not permitted to assume any role.
<code>type</code>	Can be assigned one of these strings: <code>normal</code> , indicating that this account is for a normal user, one who logs in; or <code>role</code> , indicating that this account is for a role. Roles can only be assumed by a normal user after the user has logged in.
<code>project</code>	Can be assigned a name of one project from the <code>project(4)</code> database to be used as a default project to place the user in at login time. For more information, see <code>getdefaultproj(3PROJECT)</code> .

EXAMPLES **EXAMPLE 1** Assigning a Profile to Root

The following example entry assigns to root the `All` profile, which allows root to use all commands in the system, and also assigns two authorizations:

```
root:::auths=solaris.*,solaris.grant;profiles=All;type=normal
```

The `solaris.*` wildcard authorization shown above gives root all the `solaris` authorizations; and the `solaris.grant` authorization gives root the right to grant to others any `solaris` authorizations that root has. The combination of authorizations enables root to grant to others all the `solaris` authorizations. See `auth_attr(4)` for more about authorizations.

FILES `/etc/nsswitch.conf`
`/etc/user_attr`

NOTES When deciding which authorization source to use, keep in mind that NIS+ provides stronger authentication than NIS.

The root user is usually defined in local databases for a number of reasons, including the fact that root needs to be able to log in and do system maintenance in single-user mode, before the network name service databases are available. For this reason, an entry should exist for root in the local `user_attr` file, and the precedence shown in the example `nsswitch.conf(4)` file entry under **EXAMPLES** is highly recommended.

Because the list of legal keys is likely to expand, any code that parses this database must be written to ignore unknown key-value pairs without error. When any new keywords are created, the names should be prefixed with a unique string, such as the company's stock symbol, to avoid potential naming conflicts.

user_attr(4)

In the `attr` field, escape the following symbols with a backslash (\) if you use them in any value: colon (:), semicolon (;), carriage return (\n), equals (=), or backslash (\).

utmp(4)

NAME	utmp, wtmp – utmp and wtmp database entry formats
SYNOPSIS	<pre>#include <utmp.h> /var/adm/utmp /var/adm/wtmp</pre>
DESCRIPTION	<p>The utmp and wtmp database files are obsolete and are no longer present on the system. They have been superseded by the extended database contained in the utmpx and wtmpx database files. See utmpx(4).</p> <p>It is possible for /var/adm/utmp to reappear on the system. This would most likely occur if a third party application that still uses utmp recreates the file if it finds it missing. This file should not be allowed to remain on the system. The user should investigate to determine which application is recreating this file.</p>
SEE ALSO	utmpx(4)

NAME	utmpx, wtmpx – utmpx and wtmpx database entry formats				
SYNOPSIS	<pre>#include <utmpx.h> /var/adm/utmpx /var/adm/wtmpx</pre>				
DESCRIPTION	<p>The utmpx and wtmpx files are extended database files that have superseded the obsolete utmp and wtmp database files.</p> <p>The utmpx database contains user access and accounting information for commands such as <code>who(1)</code>, <code>write(1)</code>, and <code>login(1)</code>. The wtmpx database contains the history of user access and accounting information for the utmpx database.</p>				
USAGE	Applications should not access these databases directly, but should use the functions described on the <code>getutxent(3C)</code> manual page to interact with the utmpx and wtmpx databases to ensure that they are maintained consistently.				
FILES	<table><tr><td><code>/var/adm/utmpx</code></td><td>user access and administration information</td></tr><tr><td><code>/var/adm/wtmpx</code></td><td>history of user access and administrative information</td></tr></table>	<code>/var/adm/utmpx</code>	user access and administration information	<code>/var/adm/wtmpx</code>	history of user access and administrative information
<code>/var/adm/utmpx</code>	user access and administration information				
<code>/var/adm/wtmpx</code>	history of user access and administrative information				
SEE ALSO	<code>wait(2)</code> , <code>getutxent(3C)</code> , <code>wstat(3XFN)</code>				

vfstab(4)

NAME	vfstab – table of file system defaults							
DESCRIPTION	<p>The file <code>/etc/vfstab</code> describes defaults for each file system. The information is stored in a table with the following column headings:</p> <table><thead><tr><th>device to mount</th><th>device to fsck</th><th>mount point</th><th>FS type</th><th>fsck pass</th><th>mount at boot</th><th>mount options</th></tr></thead></table> <p>The fields in the table are space-separated and show the resource name (<i>device to mount</i>), the raw device to fsck (<i>device to fsck</i>), the default mount directory (<i>mount point</i>), the name of the file system type (<i>FS type</i>), the number used by fsck to decide whether to check the file system automatically (<i>fsck pass</i>), whether the file system should be mounted automatically by mountall (<i>mount at boot</i>), and the file system mount options (<i>mount options</i>). (See respective mount file system man page below in SEE ALSO for <i>mount options</i>.) A '-' is used to indicate no entry in a field. This may be used when a field does not apply to the resource being mounted.</p> <p>The <code>getvfsent(3C)</code> family of routines is used to read and write to <code>/etc/vfstab</code>.</p> <p><code>/etc/vfstab</code> can be used to specify swap areas. An entry so specified, (which can be a file or a device), will automatically be added as a swap area by the <code>/sbin/swapadd</code> script when the system boots. To specify a swap area, the <i>device-to-mount</i> field contains the name of the swap file or device, the <i>FS-type</i> is "swap", <i>mount-at-boot</i> is "no" and all other fields have no entry.</p>	device to mount	device to fsck	mount point	FS type	fsck pass	mount at boot	mount options
device to mount	device to fsck	mount point	FS type	fsck pass	mount at boot	mount options		
EXAMPLES	<p>The following are vfstab entries for various file system types supported in the Solaris operating environment.</p> <p>EXAMPLE 1 NFS and UFS Mounts</p> <p>The following entry invokes NFS to automatically mount the directory <code>/usr/local</code> of the server <code>example1</code> on the client's <code>/usr/local</code> directory with read-only permission:</p> <pre>example1:/usr/local - /usr/local nfs - yes ro</pre> <p>The following example assumes a small departmental mail setup, in which clients mount <code>/var/mail</code> from a server <code>mailsvr</code>. The following entry would be listed in each client's vfstab:</p> <pre>mailsvr:/var/mail - /var/mail nfs - yes intr,bg</pre> <p>The following is an example for a UFS file system in which logging is enabled:</p> <pre>/dev/dsk/c2t10d0s0 /dev/rdisk/c2t10d0s0 /export/local ufs 3 yes logging</pre> <p>See <code>mount_nfs(1M)</code> for a description of NFS mount options and <code>mount_ufs(1M)</code> for a description of UFS options.</p>							

EXAMPLE 2 pcfs Mounts

The following example mounts a `pcfs` file system on a fixed hard disk on an (Intel Architecture) IA machine:

```
/dev/dsk/c1t2d0p0:c - /win98 pcfs - yes -
```

The example below mounts a Jaz drive on a SPARC machine. Normally, the volume management daemon (see `vold(1M)`) handles mounting of removable media, obviating a `vfstab` entry. If you choose to specify a device that supports removable media in `vfstab`, be sure to set the mount-at-boot field to `no`, as below. Such an entry presumes you are not running `vold`.

```
/dev/dsk/c1t2d0s2:c - /jaz pcfs - no -
```

For removable media on a SPARC machine, the convention for the slice portion of the disk identifier is to specify `s2`, which stands for the entire medium.

For `pcfs` file systems on IA machines, note that the disk identifier uses a `p` (`p0`) and a logical drive (`c`, in the `/win98` example above) for a `pcfs` logical drive. See `mount_pcfs(1M)` for syntax for `pcfs` logical drives and for `pcfs`-specific mount options.

EXAMPLE 3 CacheFS Mount

Below is an example for a CacheFS file system. Because of the length of this entry and the fact that `vfstab` entries cannot be continued to a second line, the `vfstab` fields are presented here in a vertical format. In re-creating such an entry in your own `vfstab`, you would enter values as you would for any `vfstab` entry, on a single line.

```
device to mount: svr1:/export/abc
device to fsck: /usr/abc
mount point: /opt/cache
FS type: cachefs
fsck pass: 7
mount at boot: yes
mount options:
local-access,bg,nosuid,demandconst,backfstype=nfs,cachedir=/opt/cache
```

See `mount_cachefs(1M)` for CacheFS-specific mount options.

EXAMPLE 4 Loopback File System Mount

The following is an example of mounting a loopback (`lofs`) file system:

```
/export/test - /opt/test lofs - yes -
```

See `lofs(7FS)` for an overview of the loopback file system.

SEE ALSO `fsck(1M)`, `mount(1M)`, `mount_cachefs(1M)`, `mount_hsf(1M)`, `mount_nfs(1M)`, `mount_tmpfs(1M)`, `mount_ufs(1M)`, `swap(1M)`, `getvfsent(3C)`

vfstab(4)

System Administration Guide: Basic Administration

vold.conf(4)

<i>special</i>	This sh(1) expression specifies the device or devices to be used. Path usually begins with /dev.
<i>shared_object</i>	The name of the program that manages this device. vold(1M) expects to find this program in /usr/lib/vold.
<i>symname</i>	The symbolic name that refers to this device. The <i>symname</i> is placed in the device directory.
<i>options</i>	The user, group, and mode permissions for the media inserted (optional).

The *special* and *symname* parameters are related. If *special* contains any shell wildcard characters (i.e., has one or more asterisks or question marks in it), then the *symname* must have a "%d" at its end. In this case, the devices that are found to match the regular expression are sorted, then numbered. The first device will have a zero filled in for the "%d", the second device found will have a one, and so on.

If the *special* specification does not have any shell wildcard characters then the *symname* parameter must explicitly specify a number at its end (see EXAMPLES below).

Actions Field Here are the explanations of the syntax for the Actions field.

<code>insert eject notify</code>	The media event prompting the event
<i>regex</i>	This sh(1) regular expression is matched against each entry in the /vol file system that is being affected by this event.
<i>options</i>	You can specify what user or group name that this event is to run as (optional).
<i>program</i>	The full path name of an executable program to be run when <i>regex</i> is matched.
<i>program args</i>	Arguments to the program.

Default Values The default vold.conf file is shown here.

```
#
# Volume Daemon Configuration file
#

# Database to use (must be first)
db db_mem.so

# Labels supported
label dos label_dos.so floppy
label cdrom label_cdrom.so cdrom
label sun label_sun.so floppy

# Devices to use
use cdrom drive /dev/dsk/c*s2 dev_cdrom.so cdrom%d
use floppy drive /dev/diskette[0-9] dev_floppy.so floppy%d
```

```
# Actions
insert /vol*/dev/fd[0-9]/* user=root /usr/sbin/rmmount
insert /vol*/dev/dsk/* user=root /usr/sbin/rmmount
eject /vol*/dev/fd[0-9]/* user=root /usr/sbin/rmmount
eject /vol*/dev/dsk/* user=root /usr/sbin/rmmount
notify /vol*/rdsk/* group=tty user=root /usr/lib/vold/volmissing -p

# List of file system types unsafe to eject
unsafe ufs hsfs pcfs
```

EXAMPLES **EXAMPLE 1** A sample vold.conf file.

To add a CD-ROM drive to the vold.conf file that does not match the default regular expression (/dev/rdsk/c*s2), you must explicitly list its device path and what symbolic name (with %d) you want the device path to have. For example, to add a CD-ROM drive that has the path /dev/rdsk/my/cdroms? (where s? are the different slices), add the following line to vold.conf (all on one line):

```
use cdrom drive /dev/rdsk/my/cdroms2 dev_cdrom.so cdrom%d
```

Then, when a volume is inserted in this CD-ROM drive, volume management will assign it the next symbolic name. For example, if two CD-ROMs match the default regular expression, they would be named cdrom0 and cdrom1; and any that match the added regular expression would be named starting with cdrom2.

For a diskette that does not match the vold.conf default regular expression (/dev/floppy[0-9]), a similar line would have to be added for the diskette. For example, to add a diskette whose path was /dev/my/fd0, you would add the following to vold.conf:

```
use floppy drive /dev/my/fd0 dev_floppy.so floppy%d
```

SEE ALSO sh(1), volcancel(1), volcheck(1), volmissing(1), rmmount(1M), rpc.smserverd(1M), vold(1M), rmmount.conf(4), volfs(7FS)

NOTES Volume Management manages both the block and character device for CD-ROMs and floppy disks; but, to make the configuration file easier to set up and scan, only one of these devices needs to be specified. If you follow the conventions specified below, Volume Management figures out both device names if only one of them is specified. For example, if you specify the block device, it figures out the pathname to the character device; if you specify the pathname to the character device, it figures out the block device.

CD-ROM Naming Conventions

The CD-ROM pathname must have a directory component of rdsk (for the character device) and dsk for the block device. For example, if you specify the character device using the line:

```
use cdrom drive /dev/rdsk/my/cdroms2 dev_cdrom.so cdrom%d
```

vold.conf(4)

then it is assumed that the block device is at

```
/dev/dsk/my/cdroms2
```

**Floppy Disk
Naming
Conventions**

For floppy disks, Volume Management requires that the device pathnames end in either `rfd[0-9]` or `rdiskette[0-9]` for the character device, and `fd[0-9]` or `diskette[0-9]` for the block device. As with the other removable disks, it generates either the block name given the character name, or the character name given the block name.

NAME	warn.conf – Kerberos warning configuration file
SYNOPSIS	<code>/etc/krb5/warn.conf</code>
DESCRIPTION	<p>The <code>warn.conf</code> file contains configuration information specifying how users will be warned by the <code>ktkt_warnd</code> daemon about ticket expiration on a Kerberos client. Each Kerberos client host must have a <code>warn.conf</code> file in order for users on that host to get Kerberos warnings from the client. Entries in the <code>warn.conf</code> file must have the following format:</p> <pre><i>principal</i> <i>syslog</i> <i>terminal</i> <i>mail</i> <i>time</i> [<i>email_address</i>]</pre> <p><i>principal</i> The principal name to be warned. The '*' wildcard can be used to specify groups of principals.</p> <p><i>syslog</i> Sends the warnings to the system's syslog. Depending on the <code>/etc/syslog.conf</code> file, syslog entries are written to the <code>/var/adm/messages</code> file and/or displayed on the terminal.</p> <p><i>terminal</i> Sends the warnings to display on the terminal.</p> <p><i>mail</i> Sends the warnings as email to the address specified by <i>email_address</i>.</p> <p><i>time</i> Specifies how much time before the TGT expires when a warning should be sent. The default time value is seconds, but you can specify <i>h</i> (hours) and <i>m</i> (minutes) after the number to specify other time values.</p> <p><i>email_address</i> Specifies the email address at which to send the warnings. This field must be specified only with the <code>mail</code> field.</p>
EXAMPLES	<p>EXAMPLE 1 Specifying warnings</p> <p>The following <code>warn.conf</code> entry specifies that warnings will be sent to the syslog 5 minutes before the expiration of the TGT for all principals, in the form:</p> <pre>"jdb@ACME.COM: your kerberos credentials expire in 5 minutes".</pre> <pre>* syslog 5m</pre>
FILES	<code>/usr/lib/krb5/ktkt_warnd</code> Kerberos warning daemon
SEE ALSO	<code>ktkt_warnd(1M)</code> , <code>SEAM(5)</code>

xferlog(4)

NAME	xferlog – FTP Server transfer log file																																						
SYNOPSIS	/var/log/xferlog																																						
DESCRIPTION	<p>The xferlog file contains transfer logging information from the FTP Server, in <code>ftpd(1M)</code>. You can use the logfile capability to change the location of the log file. See <code>ftpaccess(4)</code>.</p> <p>Each server entry is composed of a single line of the following form. All fields are separated by spaces.</p> <pre><i>current-time transfer-time remote-host file-size filename</i> <i>transfer-type special-action-flag direction access-mode username</i> <i>service-name authentication-method authenticated-user-id completion-status</i></pre> <p>The fields are defined as follows:</p> <table><tr><td><i>current-time</i></td><td>The current local time in the form DDD MMM dd hh:mm:ss YYYY, where:</td></tr><tr><td>DDD</td><td>Is the day of the week</td></tr><tr><td>MMM</td><td>Is the month</td></tr><tr><td>dd</td><td>Is the day of the month</td></tr><tr><td>hh</td><td>Is the hour</td></tr><tr><td>mm</td><td>Is the minutes</td></tr><tr><td>ss</td><td>Is the seconds</td></tr><tr><td>YYYY</td><td>Is the year</td></tr><tr><td><i>transfer-time</i></td><td>The total time in seconds for the transfer</td></tr><tr><td><i>remote-host</i></td><td>The remote host name</td></tr><tr><td><i>file-size</i></td><td>The number of bytes transferred</td></tr><tr><td><i>filename</i></td><td>The name of the transferred file</td></tr><tr><td><i>transfer-type</i></td><td>A single character indicating the type of transfer:</td></tr><tr><td>a</td><td>Indicates an ascii transfer</td></tr><tr><td>b</td><td>Indicates a binary transfer</td></tr><tr><td><i>special-action-flag</i></td><td>One or more single character flags that indicate any special action taken. The <i>special-action-flag</i> can have one of more of the following values:</td></tr><tr><td>C</td><td>File was compressed</td></tr><tr><td>U</td><td>File was uncompressed</td></tr><tr><td>T</td><td>File was archived, for example, by using <code>tar(1)</code></td></tr></table>	<i>current-time</i>	The current local time in the form DDD MMM dd hh:mm:ss YYYY, where:	DDD	Is the day of the week	MMM	Is the month	dd	Is the day of the month	hh	Is the hour	mm	Is the minutes	ss	Is the seconds	YYYY	Is the year	<i>transfer-time</i>	The total time in seconds for the transfer	<i>remote-host</i>	The remote host name	<i>file-size</i>	The number of bytes transferred	<i>filename</i>	The name of the transferred file	<i>transfer-type</i>	A single character indicating the type of transfer:	a	Indicates an ascii transfer	b	Indicates a binary transfer	<i>special-action-flag</i>	One or more single character flags that indicate any special action taken. The <i>special-action-flag</i> can have one of more of the following values:	C	File was compressed	U	File was uncompressed	T	File was archived, for example, by using <code>tar(1)</code>
<i>current-time</i>	The current local time in the form DDD MMM dd hh:mm:ss YYYY, where:																																						
DDD	Is the day of the week																																						
MMM	Is the month																																						
dd	Is the day of the month																																						
hh	Is the hour																																						
mm	Is the minutes																																						
ss	Is the seconds																																						
YYYY	Is the year																																						
<i>transfer-time</i>	The total time in seconds for the transfer																																						
<i>remote-host</i>	The remote host name																																						
<i>file-size</i>	The number of bytes transferred																																						
<i>filename</i>	The name of the transferred file																																						
<i>transfer-type</i>	A single character indicating the type of transfer:																																						
a	Indicates an ascii transfer																																						
b	Indicates a binary transfer																																						
<i>special-action-flag</i>	One or more single character flags that indicate any special action taken. The <i>special-action-flag</i> can have one of more of the following values:																																						
C	File was compressed																																						
U	File was uncompressed																																						
T	File was archived, for example, by using <code>tar(1)</code>																																						

	<u> </u>	No action was taken.
<i>direction</i>		The direction of the transfer. <i>direction</i> can have one of the following values:
	o	Outgoing
	i	Incoming
<i>access-mode</i>		The method by which the user is logged in. <i>access-mode</i> can have one of the following values:
	a	For an anonymous user.
	g	For a passworded guest user. See the description of the <code>guestgroup</code> capability in <code>ftppaccess(4)</code> .
	r	For a real, locally authenticated user
<i>username</i>		The local username, or if anonymous, the ID string given
<i>service-name</i>		The name of the service invoked, usually <code>ftp</code>
<i>authentication-method</i>		The method of authentication used. <i>authentication-method</i> can have one of the following values:
	0	None
	1	<i>RFC 931</i> authentication
<i>authenticated-user-id</i>		The user ID returned by the authentication method. A <code>*</code> is used if an authenticated user ID is not available.
<i>completion-status</i>		A single character indicating the status of the transfer. <i>completion-status</i> can have one of the following values:
	c	Indicates complete transfer
	i	Indicates incomplete transfer

ypfiles(4)

NAME	ypfiles – Network Information Service Version 2, formerly known as YP																		
DESCRIPTION	<p>The NIS network information service uses a distributed, replicated database of dbm files (in ASCII form) contained in the <code>/var/yp</code> directory hierarchy on each NIS server. NIS has been replaced by NIS+, the new version of the Network Information Service. See <code>nis+(1)</code>. This release only supports the client functionality of NIS, (see <code>ypclnt(3NSL)</code>). The client functions are either supported by the <code>ypserv</code> process running on a machine with an earlier version of SunOS or by the NIS+ server in "YP-compatibility" mode, (see <code>rpc.nisd(1M)</code>).</p> <p>A dbm database served by the NIS server is called an NIS <i>map</i>. An NIS <i>domain</i> is a subdirectory of <code>/var/yp</code> containing a set of NIS maps on each NIS server.</p> <p>Standard nicknames are defined in the file <code>/var/yp/nicknames</code>. These names can be used in place of the full map name in the <code>ypmatch</code> and <code>ypcat</code> commands. The command <code>ypcat -x</code> can be used to display the current set of nicknames. The command <code>ypwhich -m</code> can be used to display all the available maps. Each line of the nickname file contains two fields separated by white space. The first field is the nickname and the second field is the name of the map that it expands to. The nickname cannot contain a ".".</p>																		
FILES	<code>/var/yp/nicknames</code> nicknames file																		
SEE ALSO	<code>nis+(1)</code> , <code>nisaddent(1M)</code> , <code>nissetup(1M)</code> , <code>rpc.nisd(1M)</code> , <code>ypbind(1M)</code> , <code>ypinit(1M)</code> , <code>dbm(3UCB)</code> , <code>secure_rpc(3NSL)</code> , <code>ypclnt(3NSL)</code>																		
NOTES	<p>The NIS+ server, <code>rpc.nisd</code>, when run in "YP-compatibility mode", can support NIS clients only for the standard NIS maps listed below, provided that it has been set up to serve the corresponding NIS+ tables using <code>nissetup(1M)</code> and <code>nisaddent(1M)</code>. The NIS+ server should serve the directory with the same name (case sensitive) as the domainname of the NIS client. NIS+ servers use secure RPC to verify client credentials but the NIS clients do not authenticate their requests using secure RPC. Therefore, NIS clients can look up the information stored by the NIS+ server only if the information has "read" access for an unauthenticated client (i.e. one with "nobody" NIS+ credentials).</p> <table><thead><tr><th><i>NIS maps</i></th><th><i>NIS+ tables</i></th></tr></thead><tbody><tr><td><code>passwd.byname</code></td><td><code>passwd.org_dir</code></td></tr><tr><td><code>passwd.byuid</code></td><td><code>passwd.org_dir</code></td></tr><tr><td><code>group.byname</code></td><td><code>group.org_dir</code></td></tr><tr><td><code>group.bygid</code></td><td><code>group.org_dir</code></td></tr><tr><td><code>publickey.byname</code></td><td><code>cred.org_dir</code></td></tr><tr><td><code>hosts.byaddr</code></td><td><code>hosts.org_dir</code></td></tr><tr><td><code>hosts.byname</code></td><td><code>hosts.org_dir</code></td></tr><tr><td><code>mail.byaddr</code></td><td><code>mail_aliases.org_dir</code></td></tr></tbody></table>	<i>NIS maps</i>	<i>NIS+ tables</i>	<code>passwd.byname</code>	<code>passwd.org_dir</code>	<code>passwd.byuid</code>	<code>passwd.org_dir</code>	<code>group.byname</code>	<code>group.org_dir</code>	<code>group.bygid</code>	<code>group.org_dir</code>	<code>publickey.byname</code>	<code>cred.org_dir</code>	<code>hosts.byaddr</code>	<code>hosts.org_dir</code>	<code>hosts.byname</code>	<code>hosts.org_dir</code>	<code>mail.byaddr</code>	<code>mail_aliases.org_dir</code>

compver — compatible versions file, 67
configuration file for default router(s) —
 defaultrouter, 77
configuration file for IKE policy —
 ike.config, 189
configuration file for in.named —
 named.conf, 278

- configuration file for LDAP display template routines
 - `ldaptemplates.conf`, 242
- configuration file for LDAP filtering routines
 - `ldapfilter.conf`, 236
- configuration file for LDAP search preference routines
 - `ldapsearchprefs.conf`, 238
- configuration file for mapping between NIS+ and LDAP — NIS+LDAPmapping, 336
- configuration file for Mobile IP mobility agent
 - `mipagent.conf`, 269, 305
- configuration file for NIS security — `securenets`, 522
- configuration file for NIS+ service daemon — `rpc.nisd`, 494
- configuration file for security policy — `policy.conf`, 408
- configuration file for Service Location Protocol agents — `slp.conf`, 529
- configuration file, system log daemon — `syslogd`, 559
- copyright — copyright information file, 68
- core — core image of a terminated process file, 69

D

- default Internet protocol type — `inet_type`, 203
- defaultdomain — specify host's domain name, 75
- default_fs — specify the default file system type for local or remote file systems, 76
- defaultrouter — configuration file for default router(s), 77
- depend — software dependencies file, 78
- device instance number file — `path_to_inst`, 385
- device_allocate
 - device access control file, 80
- device_maps
 - device access control file, 82
- devices
 - access control file — `device_allocate`, 80, 82
- devices, capabilities
 - terminal and printers — `terminfo`, 570

- dfs utilities packages
 - list — `fstypes`, 129
- dfstab — file containing commands for sharing resources, 84
- DHCP
 - client identifier to IP address mappings — `dhcp_network`, 92
 - configuration parameter table— `dhcptab`, 98
 - `dhcp_network`, *See also* `pntadm`
 - `dhcp_network` — DHCP network database, 92
 - `dhcpsvc.conf` — file containing service configuration parameters for the DHCP service, 95
 - `dhcptab` — DHCP configuration parameter table, 98
- dial-up password file — `d_passwd`, 104
- dialups — list of terminal devices requiring a dial-up password, 102
- directory of files specifying supported platforms — `platform`, 402
- `dir_ufs` — format of ufs directories, 103
- disk drive configuration for the format command — `format.dat`, 123
- disk space requirement file — `space`, 540
- dispatcher, real-time process
 - parameters — `rt_dptbl`, 509
- dispatcher, time-sharing process
 - parameters — `ts_dptbl`, 634
- `d_passwd` — dial-up password file, 104
 - Generating An Encrypted Password, 105
- `driver.conf` — driver configuration file, 106
- drivers
 - driver for ISA devices — `isa`, 551
 - driver for PCI devices — `pci`, 387
 - driver for pseudo devices — `pseudo`, 467
 - driver for SBus devices — `vme`, 514
 - driver for SCSI devices — `scsi`, 520

E

- `eisa` — configuration file for EISA bus device drivers, 551
- ELF files — `a.out`, 26
- `environ` — user-preference variables files for AT&T FACE, 109

- .environ — user-preference variables files for AT&T FACE, 109
- environment
 - setting up an environment for user at login time — profile, 457
- ethers — Ethernet addresses of hosts on Internet, 111
- exec_attr — execution profiles database, 112
- Executable and Linking Format (ELF) files — a.out, 26
- execution profiles database — exec_attr, 112

F

- FACE
 - alias file — pathalias, 384
 - object architecture information — ott, 369
- FACE object architecture information — ott, 369
- fd — file descriptor files, 114
- file containing service configuration parameters for the DHCP service — dhcpcsvc.conf, 95
- file descriptor files — fd, 114
- file formats
 - intro, 16
- file listing users to be disallowed ftp login privileges — ftpusers, 155
- file system
 - defaults — vfstab, 656
 - mounted — mnttab, 275
 - stripe — stripe, 262
 - unstripe — stripe, 262
- file that maps sockets to transport providers — sock2path, 539
- files used by programs
 - /etc/md.conf — table of file systems to be striped, 266
 - /etc/security/device_allocate — device_allocate file, 81
 - /etc/security/device_maps — device_maps file, 82
- flash_archive — format of flash archive, 115
- format of a ufs file system volume — fs_ufs, 130
 - inode, 130
 - inode_ufs, 130

- format of flash archive — flash_archive, 115
- format.dat — disk drive configuration for the format command, 123
 - Keywords, 123
 - Syntax, 123
- forward — mail forwarding file, 22
- fspec — format specification in text files, 127
- fstypes — file that lists utilities packages for distributed file system, 129
- fs_ufs — format of a ufs file system volume, 130
- FTP Server configuration file — ftpaccess, 133
- FTP Server conversions database — ftpconversions, 149
- FTP Server individual user host access file — ftphosts, 152
- FTP Server transfer log file — xferlog, 664
- FTP Server virtual hosting configuration file — ftpservers, 153
- ftpaccess — FTP Server configuration file, 133
- ftpconversions — FTP Server conversions database, 149
- ftpgroups — FTP Server enhanced group access file, 151
- ftphosts — FTP Server individual user host access file, 152
- ftpservers — FTP Server virtual hosting configuration file, 153
- ftpusers — file listing users to be disallowed ftp login privileges, 155
- fx_dptbl — fixed priority dispatcher parameter table, 157

G

- geniconvtbl — geniconvtbl input file format, 163
- geniconvtbl input file format — geniconvtbl, 163
- graphics interface files — plot, 406
- group — local source of group information, 181

H

holidays — prime/nonprime hours for accounting system, 183
host name database — hosts, 184
hosts — host name data base, 184
hosts.equiv — trusted hosts list, 186

I

ike.config — configuration file for IKE policy, 189
ike.preshared — pre-shared keys file for IKE, 198
inetd.conf — Internet server database, 200
inet_type — default Internet protocol type, 203
init.d — initialization and termination scripts for changing init states, 204
initialization and termination scripts for changing init states — init.d, 204
inittab — script for init, 206
inode — format of a ufs file system volume, 130
inode_ufs — format of a ufs file system volume, 130
installation
 defaults file — admin, 18
Internet
 DHCP database — dhcp_network, 92
 Ethernet addresses of hosts — ethers, 111
 network name database — networks, 329
 protocol name database — protocols, 460
 services and aliases — services, 524
Internet servers database — servers, 200
ipnodes — local database associating names of nodes with IP addresses, 209
isa — configuration file for ISA bus device drivers, 551
issue — issue identification file, 211

K

Kerberos configuration file — krb5.conf, 227
Kerberos warning configuration file — warn.conf, 663

keyboard table descriptions for loadkeys and dumpkeys — keytables, 220
keytables — keyboard table descriptions for loadkeys and dumpkeys, 220
krb5.conf — Kerberos configuration file, 227

L

ldapfilter.conf — configuration file for LDAP filtering routines, 236
ldapsearchprefs.conf — configuration file for LDAP search preference routines, 238
ldaptemplates.conf — configuration file for LDAP display template routines, 242
legal annotations
 specify — note, 356
limits — header for implementation-specific constants, 246
link editor output — a.out, 26
list of network groups — netgroup, 321
list of terminal devices requiring a dial-up password — dialups, 102
llc2 — LLC2 Configuration file, 250
LLC2 Configuration file — llc2, 250
local database associating names of nodes with IP addresses — ipnodes, 209
login-based device permissions — logindevperm, 256
logindevperm — login-based device permissions, 256
loginlog — log of failed login attempts, 257
lutab, 258

M

magic — file command's magic numbers table, 259
mddb.cf — file, 261
message displayed to users attempting to log on in the process of a system shutdown — nologin, 355
mipagent.conf — configuration file for Mobile IP mobility agent, 269, 305
mnttab — mounted file system table, 275
mounted file system table — mnttab, 275

N

- name service cache daemon configuration —
 - nscd.conf
 - nscd.conf, 357
- name service switch
 - configuration file — nsswitch.conf, 360
- named.conf — configuration file for
 - in.named, 278
- nca.if — the NCA configuration file that specifies physical interfaces, 306
- ncakmod.conf — the ncakmod configuration file, 308
- ncalogd.conf — the ncalogd configuration file, 310
- netconfig — network configuration database, 316
- netgroup — list of network groups, 321
- netid — netname database, 323
- netmasks — network masks for subnetting, 325
- netname database — netid, 323
- .netrc — ftp remote login data file, 327
- Network Information Service Version 2, formerly knows as YP — ypfiles, 666
- networks connected to the system — netconfig, 316
- networks — network name database, 329
- NFS
 - remote mounted file systems — rmtab, 492
- NIS databases
 - updating — updaters, 650
- nisfiles — NIS+ database files and directory structure, 333
- NIS+LDAPmapping — configuration file for mapping between NIS+ and LDAP, 336
- nologin — message displayed to users attempting to log on in the process of a system shutdown, 355
- nonprime hours
 - accounting system — holidays, 183
- note — specify legal annotations, 356
- nscd.conf — name service cache daemon configuration, 357
- nsswitch.conf — configuration file for the name service switch, 360
- .order — installation order of software packages on product distribution media, 368

P

- package characteristics file
 - pkginfo, 393
- package contents description file
 - pkgmap, 399
- package information file — prototype, 462
- package installation order file
 - order, 368
- package table of contents description file
 - .clustertoc — clustertoc, 63
 - packetoc, 370
- .packagetoc — listing of software packages on product distribution media, 370
- packing rules file for cachefs and filesync —
 - packingrules, 374
- packingrules — packing rules file for cachefs and filesync, 374
- pam.conf — configuration file for pluggable authentication modules, 377
- passwd — password file, 381
- passwords
 - access-restricted shadow system file — shadow, 525
- pathalias — alias file for FACE, 384
- path_to_inst — device instance number file, 385
- PCI devices
 - driver class — pci, 387
- pci — drivers for PCI devices, 387
- pcmcia — PCMCIA nexus driver, 391
- PCMCIA nexus driver — pcmcia, 391
- per-user auditing data file — audit_user, 52
- phones — remote host phone numbers, 392
- pkginfo — software package characteristics file, 393
- pkgmap — listing of software package contents, 399
- platform — directory of files specifying supported platforms, 402
- plot — graphics interface files, 406
- policy.conf — configuration file for security policy, 408
- Power Management configuration file —
 - power.conf, 409
- power.conf — Power Management configuration file, 409

- .pref — user-preference variables files for AT&T
FACE, 109
- pre-shared keys file for IKE —
ike.preshared, 198
- prime hours
 - accounting system — holidays, 183
- printers — printer alias database, 417
- printers.conf — printing configuration
database, 421

 - PCSXREG, 448
 - PCUNKILL, 444
 - PCWATCH, 445
- /proc, the process file system — proc, 427
- process file system — proc, 427
- process scheduler (or dispatcher), real-time
 - parameters — rt_dptbl, 509
- process scheduler (or dispatcher), time-sharing
 - parameters — ts_dptbl, 634
- processes
 - core image of a terminated process file —
core, 69
- profile — setting up an environment for user at
login time, 457
- project — project file, 458
- project file — project, 458
- project identification file — issue, 211

- protocols — names of known protocols in
Internet, 460
- prototype — package information file, 462
- pseudo devices, 467
- pseudo — drivers for pseudo devices, 467
- publickey — publickey database for secure
RPC, 468

Q

- queuedefs — queue description file for at,
batch, and cron spooled by at or batch or
atrm, 469

R

- real-time process dispatcher
 - parameters — rt_dptbl, 509
- real-time process scheduler
 - parameters — rt_dptbl, 509
- remote authentication for hosts and users —
hosts.equiv, rhosts, 186
- remote — remote host descriptions, 481
- remote host
 - phone numbers — phones, 392
- remote login data for ftp — netrc, 327
- remote mounted file systems
 - rmtab, 492
- Remote Program Load (RPL) server
 - configuration file — rpld.conf, 507
- resolv.conf — resolver configuration file, 485
- resolver configuration file — resolv.conf, 485
- rmmount.conf — removable media mounter
configuration file
 - Default Values, 488
 - Examples, 488
- rpc — rpc program number database, 493
- RPC program names
 - for program numbers — rpc, 493
- RPC security
 - public key database — publickey, 468
- rpc.nisd — configuration file for NIS+ service
daemon, 494
- RPCSEC_GSS mechanism file
 - mech, 267

RPCSEC_GSS QOP file
—, 267
rpld.conf — Remote Program Load (RPL) server
configuration file, 507

S

SBus devices
driver class — sbus, 514
sbus — drivers for SBus devices, 514
scsfile — format of SCCS history file, 517
scheduler, real-time process
parameters — rt_dptbl, 509
scheduler, time-sharing process
parameters — ts_dptbl, 634
SCSI devices
driver class — scsi, 520
scsi — drivers for SCSI devices, 520
securenets — configuration file for NIS
security, 522
sendmail aliases file — aliases, 22
serialized registration file for the service
location protocol daemon (slpd) —
slpd.reg, 537
services — Internet services and aliases, 524
shadow password file, 525
share resources across network, commands —
dfstab, 84
shared resources, local
— sharetab, 527
sharetab — shared file system table, 527
shell database — shells, 528
shells — shell database, 528
slp.conf — configuration file for Service
Location Protocol agents, 529
slpd.reg — serialized registration file for the
service location protocol daemon
(slpd), 537
sock2path — file that maps sockets to transport
providers, 539
software dependencies — depend, 78
space — disk space requirement file, 540
specify the default file system type for local or
remote file systems — default_fs, 76
specify host's domain name —
defaultdomain, 75

sshd configuration file — sshd_config, 546
sshd_config — sshd configuration file, 546
stripe — stripe file system, 262
su command log file — sulog, 550
sulog — su command log file, 550
sysbus — drivers for system bus, 551
sysbus — drivers for EISA devices
eisa, 551
sysbus — drivers for ISA devices
isa, 551
sysidcfg — system identification configuration
file, 554
Keyword Syntax Rules, 554
Where To Put the sysidcfg File, 554
syslogd.conf — system log daemon
configuration file, 559
system — system configuration
information, 562
system identification configuration file —
sysidcfg, 554
system log configuration file —
syslogd.conf, 559

T

telnet default options file — telnetrc, 566
telnetrc — file for telnet default options, 566
term — format of compiled term file, 567
terminals
line setting information — ttydefs, 641
termination and initialization scripts for
changing init states — init.d, 204
terminfo — System V terminal capability data
base, 570
test files
format specification — fspec, 127
the NCA configuration file that specifies
physical interfaces — nca.if, 306
the ncakmod configuration file —
ncakmod.conf, 308
the ncalogd configuration file —
ncalogd.conf, 310
timezone — set default time zone, 625
timed event services
queue description file for at, batch and cron
— queuedefs, 469

- time-sharing process dispatcher
 - parameters — ts_dptbl, 634
- time-sharing process scheduler
 - parameters — ts_dptbl, 634
- timezone — default timezone data base, 626
- timezone information — zoneinfo, 668
- TNF kernel probes — tnf_kernel_probes, 627
- tnf_kernel_probes — TNF kernel probes, 627
- ttydefs — terminal line settings
 - information, 641
- ttyname
 - list of directories with terminal-related device files — ttysrch, 642

U

- ufs
 - format — dir_ufs, 103
- ufsdump — incremental dump format, 644
- updaters — configuration file for NIS
 - updating, 650
- user-preference variables files for AT&T FACE
 - environ, 109
- utmp — utmp and wtmp database entry
 - formats, 654
- utmpx — utmpx and wtmpx database entry
 - formats, 655
- .variables — user-preference variables files for AT&T FACE, 109

V

- vfstab — defaults for each file system, 656
- vold.conf — Volume Management configuration file, 659
 - Actions Field, 660
 - CD-ROM Naming Conventions, 661
 - Default Values, 660
 - Devices to Use Field, 659
 - File Format, 659
 - Floppy Disk Naming Conventions, 662
- Volume Management
 - configuration file — vold.conf, 659

W

- warn.conf — Kerberos warning configuration file, 663
- wtmp — utmp and wtmp database entry
 - formats, 654
- wtmpx — utmpx and wtmpx database entry
 - formats, 655

X

- xferlog — FTP Server transfer log file, 664

Y

- ypfiles — Network Information Service Version 2, formerly known as YP, 666

Z

- zoneinfo — timezone information, 668
